Kepler, in his *Epitom. Astron. Copern.*, and after him Dr. Halley, in his *Inquiry into the Causes of the Variation of the Needle*, Phil. Trans. N<sup>o</sup> 195, suppose our earth may be composed of several crusts or shells, one within another, and concentric to each other. If this be the case, it is possible the ring of Saturna may be the fragment or remaining ruin of his former exterior shell, the rest of which is broken or fallen down upon the body of the planet.

RING is also the name of an instrument used in navigation, for taking the altitudes of the sun, &c.

It is usually of brass, about nine inches diameter, suspended by a little swivel, 45° from the point of which is a perforation, which is the centre of a quadrant of 90°, divided in the inner concave surface.

To use it, they hold it up by the swivel, and turn it to the sun, till the sun-beams, falling through the hole, make a spot among the degrees, which marks the altitude required.

This instrument is preferred to the astrolabe, because the divisions are here larger than on the astrolabe. See *ASTROLABE*.

RING is also used for the sound or tone of a bell; which see.

The ringing of bells, though now a recreation chiefly of the lower class of people, is a very curious exercise. As for the tolling of a bell, this is nothing more than the producing of a sound by the stroke of the clapper against the side of a bell; the bell itself being in a pendant position, and at rest. In ringing, the bell, by means of a wheel and rope, is elevated to a perpendicular: in its motion to this situation, the clapper strikes forcibly on one side, and, in its return downwards, on the other side of the bell, producing at each stroke a sound. The music of bells is altogether melody; but the pleasure arising from it consists in the variety of interchanges, and the various succession and general predominance of the consonances in the sounds produced.

The practice of ringing bells in change is said to be peculiar to this country, which for this reason is called the ringing island; but the antiquity of it is not easily ascertained. There are in London several societies of ringers, particularly one known by the name of the College Youths. Merfennus has said nothing of the ringing of bells in changes; and Kircher has only calculated the possible combinations arising from a given number. See *ALTERNATIONS*.

In England, the practice of ringing is reduced to a science; and peals have been composed, which bear the names of the inventors. Some of the most celebrated peals now known were composed about fifty years ago, by Mr. Patrick, so well known as the maker of barometers.

For the method of ringing in the Low Countries, see *CARILLONS*.

RING, or *Annulus*, in *Geometry*. See *ANNULUS*.

The area of the ring included between the circumferences, A B P A, D E Q D, of two concentric circles, (*Plate XII. Geometry, fig. 12.*) is obtained by the rule given under *ANNULUS: viz.* Multiply the sum of the diameters by their difference, and the product by .7854, and the ultimate product will be the area required: for the ring being equal to the difference of the two circles, if the diameters be called D, d, and .785398, &c. = a, we shall have the ring =  $aD - ad = a \times \overline{D+d} \times \overline{D-d}$ . Hence if DW be a perpendicular to the radius CDA, DW<sup>2</sup> will be equal to  $\overline{AD \times AC + CD} = \overline{D-d} \times \overline{D+d}$ , and  $aDW^2$ , or the area of a circle whose radius is DW, will

be =  $aD^2 - ad^2$  = the area of the ring. Hence also it appears, that the ring is equal to an ellipse whose axes are  $\overline{D+d}$  and  $\overline{D-d}$ . See *ELLIPSE*.

The area of the ring may also be had, by multiplying half the sum of the circumferences by half the difference of the diameters, the product being the area. For the circumferences are equal to  $4aD$ ,  $4ad$ : therefore  $a \times \overline{D+d} = \frac{1}{2}C + \frac{1}{2}c$ ; which, by substitution in the last rule, will give  $a \times \overline{D+d} \times \overline{D-d} = \frac{1}{2}C + \frac{1}{2}c \times \overline{D-d} = \frac{1}{2}C + \frac{1}{2}c \times \frac{1}{2}\overline{D-d} = \frac{1}{2}C + \frac{1}{2}c \times \frac{1}{2}\overline{D-d}$ , as in the rule. The same rule will serve also for a part of the ring, A B E D A, included between the parts, AD, BE, of two radii, using for C and c the lengths of the intercepted arcs.

Another rule for finding the area of the ring is as follows: Multiply the perpendicular breadth of the ring, that is, the difference of the radii, by the circumference RST, (or part RS for the part A B E D A,) having the same centre with, and equally distant from, the bounding arcs. For this circumference, being equally distant from the other two, will be equal to half their sum. Hence the whole ring, or any part of it A B E D A, included between two radii, is equal to a parallelogram on the same base AD, and whose altitude is equal to RS, the middle circumference.

RING, *Solid*, is a solid returning into itself; of which every section perpendicular to the axis, or line passing through the middle, of the solid, is every where the same figure, and of the same magnitude.

To find the Surface of a solid Ring.—Multiply the axis by the perimeter of a section perpendicular to it, and the product will be the surface. *E. gr.* a workman having made for a jeweller a circular ring, or a ring whose axis forms the circumference of a circle; it is required to find the expence of the gilding, at a penny the square inch; the thickness of the ring, or the diameter of a section of it, being 2 inches; and the inner diameter, across from side to side, 18 inches. Here  $18 + 2 = 20$  = the diameter of the circle formed by the axis; and consequently  $20 \times 3.14159$  = the length of the axis. But  $2 \times 3.14159$  = the circumference of a section of it; therefore  $20 \times 3.14159 \times 2 \times 3.14159 = 40 \times 3.14159^2 = 394.785$  square inches, nearly, = 394.785 pence = 1*l.* 12*s.* 10½*d.* nearly, the expence required.

To find the Solidity of a Ring.—Multiply the axis by a section perpendicular to it, and the product will be the solidity. *E. gr.* required the price of a ring of iron, whose dimensions are the same with those in the last example, at four-pence a pound; a cubic inch of iron weighing 4.423 ounces avoirdupois. Here the area of a section being  $2 \times .785398 = 3.14159$ , which expresses half the circumference, and the axis being the same as before, the solidity will evidently be expressed by half the surface in the last example; *i. e.* the solidity = 197.3925 cubic inches, which multiplied by 4.423, gives 873.065 ounces = 54.56657 pounds; which, at 4*d.* each, will amount to 18*s.* 2¼*d.*, the price required.

It is needless to multiply examples, as the mode of operation is the same in all forms, with those for prisms, both with regard to the surfaces and solidities: for it is evident that any ring is equal to a prism, whose altitude and end are respectively equal to the axis and section of the ring, both as to surface and solidity, and, therefore, the rules for them both must be the same; and, on this account, any demonstration of the rules for rings is unnecessary. Hutton's *Mensuration*.

RINGS of Colours, in *Optics*, a phenomenon first observed

in thin plates of various substances, by Mr. Boyle, and Dr. Hooke, but afterwards more fully explained by Sir Isaac Newton. Mr. Boyle having exhibited a variety of colours in colourless liquors, by shaking them till they rose in bubbles, as well as in bubbles of soap and water, and also in turpentine, procured glass blown so thin as to exhibit similar colours; and he observes, that a feather of a proper shape and size, and also a black ribbon held at a proper distance between his eye and the sun, shewed a variety of little rainbows, as he calls them, with very vivid colours. Boyle's Works by Shaw, vol. ii. p. 70.

Dr. Hooke, about nine years after the publication of Mr. Boyle's Treatise on Colours, exhibited the coloured bubble of soap and water, and observed, that though at first it appeared white and clear, yet as the film of water became thinner, there appeared upon it all the colours of the rainbow. He also described the beautiful colours that appear in thin plates of Muscovy glass; which appeared, through the microscope, to be ranged in rings surrounding the white specks or flaws in them, and with the same order of colours as those of the rainbow, and which were often repeated ten times. He also took two thin pieces of glass, ground plain and polished, and putting them one upon another, pressed them till there began to appear a red coloured spot in the middle; and pressing them closer, he observed several rings of colours encompassing the first place, till, at last, all the colours disappeared out of the middle of the circles, and the central spot appeared white. The first colour that appeared was red, then yellow, then green, then blue, then purple, then red again; yellow, green, blue, and purple; and again in the same order, so that he sometimes counted nine or ten of these circles, the red immediately next to the purple; and the last colour that appeared before the white was blue; so that it began with red, and ended with purple. These rings, he says, would change their places, by changing the position of the eye, so that, the glasses remaining the same, that part which was red in one position of the eye, was blue in a second, green in the third, &c. Birch's Hist. of the Royal Society, vol. iii. p. 54.

Sir Isaac Newton, having demonstrated that every different colour consists of rays which have a different and specific degree of refrangibility, and that natural bodies appear of this or that colour, according to their disposition to reflect this or that species of rays (see COLOUR), pursued the hint suggested by the experiments of Dr. Hooke, already recited, and casually noticed by himself, with regard to thin transparent substances. Upon compressing two prisms hard together, in order to make their sides touch one another, he observed, that in the place of contact they were perfectly transparent, which appeared like a dark spot; and when it was looked through, it seemed like a hole in that air, which was formed into a thin plate, by being impressed between the glasses. When this plate of air, by turning the prisms about their common axis, became so little inclined to the incident rays, that some of them began to be transmitted, there arose in it many slender arcs of colours, which increased, as the motion of the prisms was continued, and bended more and more about the transparent spot, till they were completed into circles, or rings, surrounding it; and afterwards they became continually more and more contracted.

By another experiment with two object-glasses, he was enabled to observe distinctly the order and quality of the colours from the central spot, to a very considerable distance. Next to the pellucid central spot, made by the contact of the glasses, succeeded blue, white, yellow, and red.

The next circuit immediately surrounding these consisted of violet, blue, green, yellow, and red. The third circle of colours was purple, blue, green, yellow, and red. The fourth circle consisted of green and red. All the succeeding colours became more and more imperfect and dilute, till, after three or four revolutions, they ended in perfect whiteness.

In order to determine the thickness of the plate of air, by which he supposed the colours were produced, he measured the diameters of the first six circles, at their most lucid parts, and found their squares to be in the arithmetical progression of the odd numbers 1, 3, 5, 7, 9, 11; and hence he concluded, that the intervals of the glasses at these circles must be in the same progression. He also measured the diameters of the dark or faint rings between the more lucid colours, and found their squares to be in the arithmetical progression of the even numbers 2, 4, 6, 8, 10, 12; and he concluded, after an accurate mensuration, the thickness of the air at the darkest part of the first dark ring, made by perpendicular rays, to be in the nearest round numbers  $\frac{3}{10000}$ th part of an inch, half of which, multiplied by the progression 1, 3, 5, 7, 9, 11, &c. gives the thickness of the air at the most luminous parts of all the brightest rings, their arithmetical means being its thickness at the darkest parts of all the dark ones. In examining the under side of the thin plate, in order to observe what light was transmitted, he found that the central spot was white, and the order of the colours was yellowish-red; black, violet, blue, white, yellow, red; violet, blue, green, yellow, red, &c.; but these colours were very faint and dilute, except when the light was transmitted very obliquely through the glasses. When he put water between the glasses, and measured the rings again, he found the proportion of their diameters to the diameters of the like circles made by air, to be about 7 to 8; so that the intervals of the glasses, at similar circles, caused by water and air, were about 3 to 4.

When these rings were examined in a darkened room, by the coloured light of a prism cast on a sheet of white paper, they became more distinct, and visible to a far greater number than in the open air. He sometimes saw more than twenty of them, whereas in the open air he could not discern above eight or nine.

From other curious observations on these rings, made by different kinds of light thrown upon them, he inferred, that the thicknesses of the air between the glasses, where the rings are successively made, by the limits of the seven colours, red, orange, yellow, green, blue, indigo, and violet, in order, are one to another as the cube roots of the squares of the eight lengths of a chord, which found the notes in an octave, *sol, la, fa, sol, la, mi, fa, sol*; that is, as the cube roots of the squares of the numbers 1,  $\frac{3}{2}$ ,  $\frac{4}{3}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ ,  $\frac{2}{3}$ ,  $\frac{1}{6}$ ,  $\frac{1}{2}$ . These rings appeared of that prismatic colour with which they were illuminated; and by projecting the prismatic colours immediately upon the glasses, he found that the light, which fell on the dark places between the coloured rings, was transmitted through the glasses without any change of colour. From this circumstance he thought that the origin of these rings is manifest; because the air between the glasses is disposed, according to its various thickness, in some places to reflect, and in others to transmit the light of any particular colour, and in the same place to reflect that of one colour, where it transmits that of another.

In examining the phenomena of colours made by a denser medium surrounded by a rarer, such as those which appear in plates of Muscovy glass, bubbles of soap and water, &c. the colours were found to be much more vivid than the others, which were made with a rarer medium surrounded

by a denser. From the preceding phenomena it is an obvious deduction, that the transparent parts of bodies, according to their several sizes, reflect rays of one colour, and transmit those of another; on the same account that thin plates, or bubbles, reflect or transmit those rays; and this Newton supposed to be the reason of all their colours. Hence also he has inferred, that the size of those component parts of natural bodies that affect the light, may be conjectured by their colours. See COLOUR and REFLECTION.

Sir Isaac Newton, pursuing his discoveries concerning the colours of thin substances, found that the same were also produced by plates of a considerable thickness, divisible into lesser thicknesses. The rings formed in both cases have the same origin, with this difference, that those of the thin plates are made by the alternate reflections and transmissions of the rays at the second surface of the plate, after one passage through it; but that, in the case of a glass speculum, concave on one side, and convex on the other, and quicksilver over on the convex side, the rays go through the plate, and return before they are alternately reflected and transmitted. Newton's Optics, p. 169, &c. or Newton's Opera, Horsley's edit. vol. iv. p. 121, &c. p. 184, &c.

The abbé Mazeas, in his experiments on the rings of colours that appear in thin plates, has discovered several important circumstances attending them, which were overlooked by the sagacious Newton, and which tend to invalidate his theory for explaining them. In rubbing the flat side of an object-glass against another piece of flat and smooth glass, he found that they adhered very firmly together after this friction, and that the same colours were exhibited between these plane glasses, which Newton had observed between the convex object-glass of a telescope, and another that was plane; and that the colours were in proportion to their adhesion. When the surfaces of pieces of glass, that are transparent and well polished, are equally pressed, a resistance will be perceived; and wherever this is felt, two or three very fine curve lines will be discovered, some of a pale red, and others of a faint green. If the friction be continued, the red and green lines increase in number at the place of contact; the colours being sometimes mixed without any order, and sometimes disposed in a regular manner; in which case the coloured lines are generally concentric circles, or ovals, more or less elongated, as the surfaces are more or less united. When the colours are formed, the glasses adhere with considerable force; but if the glasses be separated suddenly, the colours will appear immediately upon their being put together, without the least friction. Beginning with the slightest touch, and increasing the pressure by insensible degrees, there first appears an oval plate of a faint red, and in the centre of it a spot of light green, which enlarges by the pressure, and becomes a green oval, with a red spot in the centre; and this enlarging, in its turn, discovers a green spot in its centre. Thus the red and green succeed one another in turns, assuming different shades, and having other colours mixed with them. The greatest difference between these colours exhibited between plane surfaces, and those by curve ones, is, that, in the former case, pressure alone will not produce them, except in the case above-mentioned. In rubbing together two prisms, with very small refracting angles, which were joined so as to form a parallelepiped, the colours appeared with a surprising lustre at the places of contact, and differently coloured ovals appeared. In the centre there was a black spot, bordered by a deep purple; next to this appeared violet, blue, orange, red tinged with purple, light green, and faint purple. The other rings appeared to the naked eye to consist of nothing but faint reds and greens. When

these coloured glasses were suspended over the flame of a candle, the colours disappeared suddenly, though they still adhered; but being suffered to cool, the colours returned to their former places, in the same order as before. At first the abbé Mazeas had no doubt but that these colours were owing to a thin plate of air between the glasses, to which Newton has ascribed them; but the remarkable differences in the circumstances attending those produced by the flat plates, and those produced by the object-glasses of Newton, convinced him that the air was not the cause of this appearance. The colours of the flat plates vanished at the approach of flame, but those of the object-glasses did not. Nor was this difference owing to the plane glasses being less compressed than the convex ones; for though the former were compressed ever so much by a pair of forceps, it did not in the least hinder the effect of the flame. Afterwards he put both the plane glasses and the convex ones into the receiver of an air-pump, suspending the former by a thread, and keeping the latter compressed by two strings; but he observed no change in the colours of either of them, in the most perfect vacuum that he could make. Suspecting still that the air adhered to the surface of the glasses, so as not to be separated from them by the force of the pump, he had recourse to other experiments, which rendered it still more improbable that the air should be the cause of these colours. Having laid the coloured plates, after warming them gradually, on burning coals; and thus, when they were nearly red, rubbing them together, he observed the same coloured circles and ovals as before. When he ceased to press upon them, the colours seemed to vanish; but they returned, as he renewed the friction. In order to determine whether the colours were owing to the thickness of some matter interposed between the glasses, he rubbed them together with suet and other soft substances between them; yet his endeavours to produce the colours had no effect. However, by continuing the friction with some degrees of violence, he observed, that a candle appeared through them encompassed with two or three concentric greens, and with a lively red inclining to yellow, and a green like that of an emerald; and at length the rings assumed the colours of blue, yellow, and violet. The abbé was confirmed in his opinion that there must be some error in Newton's hypothesis, by considering that, according to his measures, the colours of the plates varied with the difference of a millionth part of an inch; whereas he was satisfied that there must have been much greater differences in the distance between his glasses, when the colours remained unchanged. From other experiments he concluded, that the plate of water introduced between the glasses was not the cause of their colours, as Newton apprehended; and that the coloured rings could not be owing to the compression of the glasses. After all he adds, that the theory of light, thus reflected from thin plates, is too delicate a subject to be completely ascertained by a small number of observations. Berlin Mem. for 1752, or Memoirs Prentes, vol. ii. p. 28—43.

For M. du Tour's experiments and observations, see Mem. Pref. vol. iv. p. 288.

M. Muschenbroeck is also of opinion, that the colours of thin plates do not depend upon the air; but as to the cause he is not satisfied. Introd. ad Phil. Nat. vol. ii. p. 738. See on this subject Priestley's Hist. of Light, &c. per. 6. sect. 5. p. 498, &c.

Sir Isaac Newton's explanation of the appearance of the above-mentioned coloured concentric rings, who accounts for the production of them by ascribing to the rays of light certain fits of easy reflection and easy transmission alternately returning and taking place with each ray at certain

certain stated intervals, not being satisfactory to Dr. Herschel, he instituted a series of experiments with a view of investigating the cause of these phenomena. Newton's hypothesis appears to him not easily reconcilable with the minuteness and extreme velocity of the particles of which these rays, according to the Newtonian theory, are composed. The detail of this celebrated astronomer's experiments would far exceed our limits; we must therefore content ourselves with referring for an account of them to the Phil. Trans. for 1807, vol. xvii. pt. 2. and with merely stating the consequences which he has deduced from them.

It is evident, says our author, that the phenomena of concentric rings must have an adequate cause, either in the very nature or motion of the rays of light, or in the modifications that are given to them by the two essential surfaces that act upon them at the time of the formation of the rings. Hence he infers, that the true cause may be reduced to an alternative that may be determined: for if it can be shewn, that a disposition of the rays of light to be alternately reflected and transmitted cannot account for the phenomena which this hypothesis is to explain, a proposal of accounting for them by modifications that may be proved, even on the principles of sir Isaac Newton, to have an existence, will be readily admitted. Accordingly Dr. Herschel offers some arguments for removing an obstacle to the investigation of the real cause of the formation of the concentric rings; for after the very plausible supposition of the alternate fits, which agrees so wonderfully well with a number of facts that have been related, it will hardly be attempted, if these should be set aside, to ascribe some other inherent property to the rays of light, by which we might account for them: and thus we shall be at liberty to turn our thoughts to a cause, that may be found in the modifications arising from the action of the surfaces, which have been proved to be the only essential ones in the formation of rings. Our author proceeds to observe, that concentric rings cannot be formed by an alternate reflection and transmission of the rays of light; for if we adopt one of the most simple methods of obtaining a set of concentric rings, which is that of laying a convex lens upon a plain metalline mirror, we can in this case have no transmission of rays, nor consequently any alternate reflection and transmission of them. He further observes, that alternate fits of easy reflection and easy transmission, if they exist, do not exert themselves according to the various thicknesses of thin plates of air. In the following experiment, he placed a plain well-polished piece of glass 5.6 inches long, and 2.3 thick, upon a plain metalline mirror of the same length with the glass, and in order to keep the mirror and glass at a distance from each other, he laid between them, at one end, a narrow strip of such paper as is commonly put between prints. The thickness of that which was used in this case was the 640th part of an inch. Upon the glass was put a 39-inch double convex lens; and having exposed this combination to a proper light, two complete sets of coloured rings were visible in this arrangement. The rays which convey the secondary set of rings to the eye must pass through a thin wedge of air, and if these rays are endowed with permanent fits of easy reflection and easy transmission, or absorption, their exertion, according to sir I. Newton, should be repeated at every different thickness of the plate of air, which amounts to the 388th part of an inch, of which he says, "*hac est crassitudo aeris in primo annulo obscuro radii ad perpendiculariculum incidentibus exhibitio, qua parte is annulus obscu-*

*rissimus est.*" The length of the thin wedge of air, reckoned from the line of contact, to the beginning of the interposed strip of paper, is 5.2 inches, from which, by calculation, it will have the above-mentioned thickness at  $\frac{1}{4}$ th of an inch from the contact; and therefore at  $\frac{2}{4}$ ,  $\frac{3}{4}$ ,  $\frac{4}{4}$ ,  $\frac{5}{4}$ ,  $\frac{6}{4}$ ,  $\frac{7}{4}$ ,  $\frac{8}{4}$ , &c. we shall have the thickness of air between the mirror and glass equal to  $\frac{1}{4}$ ,  $\frac{2}{4}$ ,  $\frac{3}{4}$ ,  $\frac{4}{4}$ ,  $\frac{5}{4}$ ,  $\frac{6}{4}$ ,  $\frac{7}{4}$ ,  $\frac{8}{4}$ , &c. of which the same author says that they give "*crassitudines aeris in omnibus annulis lucidis, qua parte illi lucidissimi sunt.*" Hence it follows that, according to the above hypothesis, the rings of the secondary set, which extended over a space of  $\frac{1}{4}$  of an inch, should suffer more than seven interruptions of shape and colour in the direction of the wedge of air.

In order to ascertain whether such an effect had any existence, Dr. Herschel viewed the secondary set of rings upon every part of the glass-plate, by moving the convex lens from one end of it gradually to the other; and his attention being particularly directed to the third, fourth, and fifth rings, which were extremely distinct, he saw them retain their shape and colour all the time without the smallest alteration.

The same experiment was repeated with a piece of plate-glass instead of the metalline mirror, in order to give room for the fits of easy transmission, if they existed, to exert themselves, but the result was still the same; and the constancy of the brightness and colours of the rings of the secondary set plainly proved, that the rays of light were not affected by the thickness of the plate of air through which they passed.

Our author next proceeds to shew, that alternate fits of easy reflection and easy transmission, if they exist, do not exert themselves according to the various thicknesses of thin plates of glass. In proof of this he selected a well-polished plate of coach-glass 17 inches long, and about 9 broad. Its thickness at one end was  $\frac{3}{16}$ ths, and at the other  $\frac{1}{16}$ th of an inch; so that in its whole length it differed  $\frac{1}{16}$ th of an inch in thickness; and it was regularly tapering from one end to the other. This plate, with a double convex lens of 55 inches laid upon it, being placed upon a small metalline mirror, and properly exposed to the light, exhibited the usual two sets of rings. In the secondary set, which was the object of attention, 12 rings were counted, and the central space between them was estimated to be about  $1\frac{1}{2}$  times as broad as the space occupied by the 12 rings on either side; so that the whole space taken up might be reckoned equal to the breadth of 40 rings of a mean size; for the 12 rings, as usual, were gradually contracted in breadth as they receded from the centre, and by a measure of the whole space thus occupied, it was found that the breadth of a ring of a mean size was about the 308th part of an inch.

According to sir I. Newton's calculation of the action of the fits of easy reflection and easy transmission in thick glass-plates, an alternation from a reflecting to a transmitting fit requires a difference of  $\frac{1}{171}$ th part of an inch in thickness (Newton's Optics, p. 277.); and by calculation this difference took place in the glass-plate, that was used at every 80th part of an inch of its whole length. The 12 rings, as well as the central colour of the secondary set, should consequently have been broken by the exertion of the fits at every 80th part of an inch; and from the space over which these rings extended, which was about  $\frac{1}{4}$  inch, it was found, that there must have been more than 10 such interruptions or breaks in a set of which the 308th part was plainly to be distinguished. But when the glass-

plate was drawn gently over the small mirror, keeping the secondary set of rings in view, their shape and colour were found to be always completely formed.

This experiment was also repeated with a small plain glass, instead of the metalline mirror put under the large plate. In this manner it still gave the same result, with no other difference but that only six rings could be distinctly seen in the secondary set, on account of the inferior reflection of the subjacent glass.

Our author next shews, that coloured rings may be completely formed without the assistance of any thin or thick plates, either of glass or of air. Sir I. Newton placed a concave glass mirror at double its focal length from a chart, and observed, that the reflection of a beam of light admitted into a dark room, when thrown upon this mirror, gave "four or five concentric irises or rings of colours like rain-bows" (*Optics*, p. 265.); and he accounts for them by alternate fits of easy reflection and easy transmission, exerted in their passage through the glass-plate of the concave mirror. *Ibid.* p. 277.

The duke de Chaulnes concluded from his own experiments of the same phenomena, that these coloured rings depended upon "the first surface of the mirror, and that the second surface, or that which reflects them after they had passed the first, only served to collect them, and throw them upon the pasteboard, in a quantity sufficient to make them visible." (*Priestley's Hist. &c.* p. 515.) Mr. Brougham, after having considered what the two last-mentioned authors had done, says, "that upon the whole there appears reason to believe, that the rings are formed by the first surface out of the light, which, after reflection from the second surface, is scattered, and passes on to the chart." *Phil. Transf.* for 1796, p. 216.

Dr. Herschel's experiment is as follows. He placed a highly polished seven-foot mirror, but of metal instead of glass, that he might not have two surfaces, at the distance of fourteen feet from a white screen, and through a hole in the middle of it, one-tenth of an inch in diameter, he admitted a beam of the sun into his dark room, so directed as to fall perpendicularly on the mirror. In this arrangement the whole screen remained perfectly free from light, because the focus of all the rays, which came to the mirror, was by reflection thrown back into the hole through which they entered. After this preparation, an assistant strewed some hair-powder with a puff into the beam of light, while he kept his attention fixed upon the screen. As soon as the hair-powder reached the beam of light the screen was suddenly covered with the most beautiful arrangement of concentric circles, displaying all the brilliant colours of the rainbow. A great variety in the size of the rings was obtained by making the assistant strew the powder into the beam at a greater distance from the mirror; for the rings contract by an increase of the distance, and dilate on a nearer approach of the powder. This experiment, says our author, is so simple, and points out the general causes of the rings which are here produced in so plain a manner, that we may confidently say, they arise from the flexion of the rays of light on the particles of the floating powder, modified by the curvature of the reflecting surface of the mirror. From this experiment our author concludes, that the principle of thin or thick plates, either of air or glass, on which the rays might alternately exert their fits of easy reflection and easy transmission, must be given up: and that the fits themselves of course cannot be shewn to have any existence. It will hardly be necessary to add further, that the whole theory relating to the size of the parts of natural

bodies and their interstices, which Sir I. Newton has founded upon the existence of fits of easy reflection and easy transmission, exerted differently, according to the different thickness of the thin plates of which he supposes the parts of natural bodies to consist, will remain unsupported; for if these fits have no existence, the whole foundation on which the theory of the size of such parts is placed, will be taken away, and it will be necessary to explore another basis for a similar edifice. This basis, our author conceives, is to be found in the modifying power, which the two surfaces that have been proved to be essential to the formation of rings, exert upon the rays of light.

Our author having pointed out a variety of methods that serve to produce coloured concentric rings between two glasses of a proper figure applied to each other, and having proved that only two surfaces, namely, those that are in contact with each other, are essential to their formation, proceeds in the investigation of the subject to shew, that prismatic phenomena assume the shape of rings, in consequence of the sole use of spherical curves in producing them. Our author found, by an appropriate experiment, that, as spherical curves gave circular rings, cylindrical forms produce streaks; that cylindrical and spherical surfaces combined produce coloured elliptical rings; and that irregular curves produce irregular figures. Hence he infers, that the curvature of surfaces is the cause of the appearance, as well as of the shape of the coloured phenomena which are produced. If we can invariably predict, from the nature of the curves that are employed in an experiment, what will be the appearance and form of the colours that will be seen, it certainly must prove the efficacy of these curvatures in the production of such phenomena. This conclusion is further confirmed by the consideration, that coloured appearances cannot be produced between the plain surfaces of two parallel pieces of glass applied to one another.

Having proved that no more than two surfaces are essential to the formation of Newton's coloured rings, and that the configuration of the coloured phenomena arises from the curvature of one or both of the two essential surfaces, Dr. Herschel infers from these principles, that we are to distinguish between the production of the colours and that of their configuration when produced. The cause of the configuration has been already explained; and our author next proceeds to investigate the production and arrangement of the colours. The order of the colours is prismatic; that is, red, orange, yellow, green, blue, indigo, and violet. Dr. Herschel's experiments for ascertaining this arrangement are too numerous and various to be here recited. We shall therefore state the general proposition, and specify the results of the experiments by which it is established. The general proposition is, that the critical separation of the colours, which takes place at certain angles of incidence, is the primary cause of the Newtonian coloured rings between optic glasses. The results of the experiments are as follow: these experiments (for which we refer to *Phil. Transf.* for 1809, vol. xcix. pt. 2.) explain in what manner a critical separation of the colours, which takes place at certain angles of incidence, is the cause of the appearance of the blue and red bows; since the different reflexivity of the rays of light, by which Newton has accounted for the blue bow, brings on a critical separation of the blue colours, and since also the different intromissibility by which the author has explained the red bow, occasions an equally critical separation of the red ones. Dr. Herschel has not only proved that all the various appearances, which were produced by convex glasses, may be equally

equally well obtained by the use of a prism, but he has also shewn, that the great simplicity of this valuable optical instrument has cleared up great difficulties, by pointing out to us that the colours which are modified into such various shapes, are in all prismatic experiments exclusively produced by the critical separation of the rays of light. As this fact must be admitted, it certainly will not be philosophical to look for a different cause of the same or similar effects, when convex glasses, which have all the required prismatic properties, are used to produce them. In order to shew the great similarity, or rather the identity of these effects, it will be sufficient to take the most simple case of each, namely, the coloured rings that are produced when a plano-convex lens is laid with its convex side upon a plain reflecting surface: and the coloured streaks which are produced when the base of a right-angled prism is in the same manner placed upon such a surface. The results of the experiments, with the reasonings annexed to them, are contained in the following propositions. The form of rings arises from the spherical figure of the lens: the right-lined appearance of the streaks is owing to the straight figure of the plain surface of the prism. The colour of the rings may suddenly be changed; the colours of the blue bow-streak may as instantly be converted into those of the red bow. The cause of the sudden change of the rings has been shewn to be that the sets of one colour are seen by reflection, and those of the other by transmission; it has also been shewn, that the blue bow-streaks are seen by reflection, and those of the red bow by transmission. In a lens we may, at the same time, see, in half the set, the colours of the reflected, and in the other half, the colours of the transmitted rings; and in a prism held before an open window, when the eye is close to it, and when half the bow falls on the side of the room, we may see blue streaks by reflection from half the blue bow, and green streaks by transmission from half the red bow. When deep convex, or concave, glasses are laid upon the first surface of a lens, the rings are not affected by it; and when the same glasses are laid upon the first surface of a prism the streaks remain unaltered. When the convexity of the lens, which is placed on the reflecting surface, is changed, the size of the rings is also changed; and when the angle of the prism is increased or diminished, the distance of the streaks undergoes a proportional alteration. When the lens is pressed upon the plain glass, the rings increase in diameter; and by a pressure of the plain glass against the prism the distance of the streaks grows larger. To form rings by a lens, scattered rays only are required: and the same light is best for the production of streaks by a prism. Many other instances of similarity might be adduced, but it is needless. Now, as it has been clearly proved, that the critical separation of the colours, which takes place at certain angles of incidence, occasions all the phenomena of the blue and red bows, and of the streaks, rings, and other regular or irregular appearances, that may be seen in a prism, it cannot be doubted that the Newtonian rings observed between object-glasses are owing to the same cause.

Dr. Herschel concludes an elaborate paper on this subject with the following remarks on the Newtonian alternate fits of easy reflection and easy transmission.

“ In attempting to rescue the science of optics from what has been so long considered as unsatisfactory for explaining the great question about the cause of the coloured rings, I have made use of a principle, the effects of which have so near a resemblance to those of the supposititious fits of easy reflection and easy transmission, that the author of them might easily be misled by appearances. But although the principle of a critical separation of the colours, substituted for these fits, admits the reflection of some rays at the same angles of

incidence at which others are transmitted, yet since the Newtonian different refrangibility of light will account for these critical reflections within glass, and equally critical intromissions from without, we can have no longer any reason to ascribe original fits to the rays of light, which in the first part of this paper they have already been proved not to possess, and which now, in all prismatic experiments, I have shewn are not necessary for explaining appearances that may be accounted for without them.”

In the *Philos. Transactions* for 1810, vol. c. pt. 2, we have a third paper, as a supplement to the other two papers, containing additional observations on the cause of coloured concentric rings between object-glasses, and other appearances of a similar nature, in which Dr. Herschel further explains what some may have thought obscure, and obviates certain objections against his theory. His fundamental principle for explaining the colour of the rings, which he has illustrated both by reasoning and experiment, is this: that the colours in all prismatic phenomena are produced either by the interior critical separation arising from the different reflexivity of the rays which cause the blue bow, or by the exterior critical separation arising from the different intromissibility of the rays which cause the red bow. In this paper he subjects some additional arguments to those before given, in order to prove, that there are two primary prismatic bows, a blue one and a red one; and he maintains, that the red bow is a phenomenon of equal originality with the Newtonian blue bow, and that as one of these bows cannot be the converse of the other, we have two critical separations essentially different, *viz.* the reflective and intromissive. But we must refer to the author's own account, *ubi supra*.

For an account of the rings of colours produced by electrical explosions, see *COLOURS of Natural Bodies*, *CIRCULAR Spots*, and *FAIRY Circles*.

*RINGS of Flies*, in *Natural History*, the several rounds or circular portions, of which the bodies of these and other insects are composed.

In the fly kind these are crustaceous or cartilaginous, and consequently of a matter little capable of extension; many actions of these insects require, however, that their bodies, or a part at least of their bodies, should be able to inflate or distend, and contract their size occasionally. Were every ring of the body one entire scale, or shelly substance, these changes could not be easily effected; nature has therefore so provided, that the tender bodies of these little creatures are sufficiently defended, and yet all the necessary motions may be performed.

*RING*, in *Agriculture*, a sort of hoop made of iron, which is used for various purposes, as fastening horses and cattle by in the stalls. In these cases they should be made large and strong.

*RING*, in *Commerce*, a term used in reckoning at *Ham-burgh*, and is equivalent to 240 of things that are sold by number. Staves are sold in rings of 4 schoaks (a schoak being 60) and 8 pieces: 3 rings of hoghead staves, or 6 rings of barrel staves, are reckoned equal to 2 rings of pipe staves.

*RING*, a stout circle of iron in the upper part of the shank of an anchor, to which the cable is bent.

*RINGS* are also circles of iron or other metal, let over the points of bolts, whereon they are clenched, to prevent their drawing. Hatch-rings, or ring and starts, are those which are fixed in the hatches or scuttles to open or shut them with.

*RINGS in Timber*, in *Rural Economy*, the concentric layers by which the wood is formed. These rings are, according to Dr. Darwin, annually produced from the albumen, and

are supposed to be thicker on that side of the trunk of the tree which has a southern aspect than on the contrary, and thicker in those summers most favourable to vegetation than in others. It is added, that these rings, as they lose their vegetable life, and at the same time a part of their moisture, by evaporation or absorption, gradually become harder and of a darker colour, inasmuch, that by counting their number, it is said, that not only the age of the tree, but the mildness or moisture of each summer, during the time of its growth, may be estimated by the respective thickness of the rings of timber.

RING, *Base*. See BASE.

RING-Bolt, in a *Ship*, is an iron bolt with an eye at one end, in which is fitted a circular ring, and used for various purposes; particularly for hooking the tackles, by which the cannon of a ship is managed and secured. They are driven by the sides of the gun-ports in ships for securing the guns; and in the deck for stopping the cable, and are therefore called stopper-bolts. The rings are sometimes made angular, to receive many turns of lashing; such are the ring-bolts driven through the ship's side along the waist for lashing the booms and spare anchors.

RING-Bone, among *Farriers*, &c. a hard callous substance, growing in the hollow circle of the little pastern of a horse, above the coronet.

It sometimes goes quite round, like a ring, whence its name; sometimes it is hereditary, derived from the stallion or mare; but it oftener comes by accident, as from a strain, a blow of a horse, &c.

RING, *Corniche*. See CORNICHE.

RING-Dial. See DIAL.

RING-Dove. See DOVE, and COLUMBA *Palumbus*.

RING, *Fairy*. See FAIRY.

RING-Head, an engine used in stretching of cloth.

RING, *Natal*. See NATAL.

RING Ouzel or *Amsel*. See OUZEL, and TURDUS *torquatus*.

RING, *Reinforce*. See REINFORCE.

RING-Ropes, in a *Ship*, short pieces of rope, tied occasionally to the ring-bolts of the deck, to fasten the cable more securely, when the ship rides in a tempest, or turbulent sea, or rapid current. They are used more particularly in veering away the cable gradually in those circumstances, in order to freshen the haul.

RING-Scalpel. We have a description and a figure of a ring-scalpel, for assisting the delivery of women in child-birth, by Dr. Thomas Simson, in the *Medical Essays of Edinburgh*, vol. v. art. 39.

RING-Tail, in *Ornithology*, the English name for the *sub-buteo*, or *pygargus accipiter*; which has been generally supposed to be the female of the hen-harrier; but males have lately been found of this species. See FALCO *Pygargus*.

The ring-tail is a moderately large bird. It has a sort of ring, or chain of feathers, round the back part of its head, reaching to its chin on each side, which stand erect, and are brown in the middle, and of a reddish-white at the edges, and make a sort of crown, which surrounds the head; on the top of the head and cheeks the feathers are dusky, bordered with rust-colour; under each eye is a white spot; the back is dusky, the rump white, with oblong yellowish spots on each shaft; the tail is long, and its tip white; the breast and belly are of a yellowish-brown, marked with oblong dusky spots; its legs are yellow, and the inside of its mouth is black; it feeds on small birds, and its eggs are of a reddish hue, with very little clear white appearing in them. These birds fly higher than the hen-harrier, and sometimes perch on trees.

RING-Tail Eagle. See *White-tailed EAGLE*, and FALCO *Albicilla*.

RING-Tail, in a *Ship*, is a quadrilateral sail, occasionally hoisted abaft the after-leech of the boom-mainsails, to which the fore-leech is made to correspond. The head is bent to a small yard at the outer end of the gaff, and the foot is spread on the boom, which is prolonged by a piece lashed to the outer end. A triangular sail of this sort is used in light favourable winds, extended on a small mast, occasionally erected for that purpose on the taffarel of small vessels.

RING, *Trunnion*. See TRUNNION.

RING-Walk, among *Hunters*, a round walk. See HUNTING.

RING-Worm, in *Medicine*. See RINGWORM.

RING Island, in *Geography*, a small island off the coast of Massachusetts, opposite to Newbury port, to the eastward.

RINGAN, a town of Germany, in the principality of Culmbach; 14 miles S. of Culmbach.

RINGANDEE, a town of Bengal; 30 miles W. of Rogonatpour.

RINGELBERGIUS, JOACHIM-FORTIUS, in *Biography*, vernacularly Sterck, an eminent Flemish philosopher and mathematician, who flourished in the 16th century, was born at Antwerp. He was patronized by the emperor Maximilian I., in whose palace he had an apartment, and he there received his first instructions in the rudiments of learning. When he was seventeen years of age, he was sent to the university of Louvain, where he studied the learned languages, philosophy, and the mathematical sciences. He became a public professor in that university, and taught rhetoric, cosmography, the mathematics, and the Greek language, with very high reputation. So numerous were the classes which attended his lectures, that they frequently occupied his attention twelve hours every day, for a month together. In the year 1528 he went into Germany, and taught the mathematical sciences and the Greek tongue in various seminaries of that country. From Germany he went to France, where he filled the professor's chair at Paris, Orleans, Bourdeaux, and other places. He died about the year 1536. He wrote a number of esteemed works, which were published at Basil, Antwerp, and other places, and reflected honour on his learning and judgment. The titles of some of them are, "De Ratione Studii;" "De Usu et Differentiis vocum quarundam apud Latinos;" "De Usu Vocum quæ non flectuntur;" "Grammaticæ Græcæ Elementa;" "Dialectica, et Tabulæ Dialecticæ;" "De conscribendis Epistolis Lib.;" "Rhetoricæ, et quæ ad eam spectant;" "Sententiæ;" "De Formis dicendi, Lib.;" "De Periodis;" "Synonyma;" "Sphæra, five Institutionum Astronomicarum, Lib. iii.;" "Cosmographia;" "Optica;" "Chaos Mathematicum;" "Arithmetica." The whole of his works were collected and published at Leyden, in 1531.

RINGELSLOFF, in *Geography*, a town of Austria; 4 miles E.N.E. of Zisterdorff.

RINGEN, a town of Russia, in the government of Riga; the birth-place of the empress Catharine I., near Dorpat.

RINGENDORF, a town of France, in the department of the Lower Rhine; 7 miles W. of Haguenau.

RINGENT COROLLA, in *Botany* and *Vegetable Physiology*, named from its resemblance to the mouth and snout of some animal; see COROLLA. Certain English authors, literally translating the original word (*ringens*), use the ludicrous term of a *grinning corolla*.

**RINGENTHAL**, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 1 mile N. of Mitweyda.

**RINGERIKE**, a town of Norway; 24 miles N.N.E. of Christiania.

**RINGES**, in *Rural Economy*, a provincial term, signifying rows of hay, mown corn, quicks, &c.

**RINGKIOBING**, in *Geography*, a town of Denmark, on the coast of a large gulf of the North sea, to which it gives name. The inhabitants are almost wholly employed in trading to Holland and Norway. The bay affords plenty of good fish, particularly oysters. It is of a good depth, and secure, except at the entrance, which is rendered dangerous by sand-banks; 48 miles N.W. of Ripen. N. lat.  $56^{\circ} 2'$ . W. long.  $8^{\circ} 18'$ .

**RINGLEBEN**, a town of Saxony, in the principality of Eisenach; 6 miles N. of Erfurt. N. lat.  $51^{\circ} 6'$ . E. long.  $11^{\circ} 2'$ .

**RINGO'S TOWN**, a town of America, in Hunterden county, New Jersey; 15 miles N.W. of Princeton.

**RINGSTED**, a town of Denmark, in the island of Zealand, anciently a large city, but reduced by fires into a small town: but it is still famous for its court of judicature, to which lies an appeal from almost all the courts of Zealand, whereas no appeal lies from this but to the supreme court at Copenhagen; 29 miles S.W. of Copenhagen. N. lat.  $55^{\circ} 28'$ . E. long.  $11^{\circ} 48'$ .

**RINGWOOD**, a town of America, in Hunterden county; 25 miles N. of Morristown, containing 2605 inhabitants.

**RINGWOOD**, a market-town and parish in the hundred of Ringwood, New Forest, west division, county of Southampton, England, is situated on the eastern bank of the river Avon, at the distance of 14 miles W. by S. from Southampton, and 90 miles S.W. by W. from London. This town is of great antiquity, and is supposed by Camden to have been the Regnum of the Romans, which others, however, have fixed, with greater probability, at Chichester, in Suffex. But whatever it may have been during the Roman government, it unquestionably attained considerable importance in the time of the Saxons; and in Domesday book, it is estimated at a higher value than Thuinam, or Christchurch.

Ringwood is noted for its breweries of strong beer and ale. A market is held here on Wednesday, weekly; and there are fairs on the 10th of July, and 11th of December. The petty sessions for New Forest, west division, are holden in this town. The unfortunate duke of Monmouth is very generally stated to have been taken in a field near Ringwood, after his defeat at Sedgemoor; but this statement is erroneous, that prince having been actually seized in the woodlands in Dorsetshire. According to the parliamentary returns of 1811, the town and parish contained 658 houses, and a population of 3269 persons.

North from Ringwood is the village of Ellingham, where formerly was a religious house, founded by William de Salariis, in the reign of Henry II., and appropriated as a cell to the abbey of St. Saviour le Vicompte, in Normandy. When the alien priories in this country were dissolved, Henry VI. granted Ellingham and its possessions to the college at Eton. Some remains of the buildings of this establishment are supposed to form the nave of the present church, and the opinion is certainly not improbable, as it is more ancient than the rest of the fabric. The altar-piece here is a painting of the Day of Judgment, presented to the parish by the late lord Windsor, whose ancestor, brigadier Windsor, brought it from Port St. Mary, in the bay of Cadiz, among the trophies of an expedition against that city in the year 1702.

In the church-yard is a plain stone, to the memory of dame Alicia Lisle, whom the blood-thirsty Jeffreys condemned to be executed in her old age, on a charge of harbouring known rebels in her mansion at Moyles-Court. This mansion is still standing, surrounded by a very pleasant, but small, park. Its former possessors, the Lisles, were originally settled in the Isle of Wight, where they had large estates, and whence they derived their name. Colonel John Lisle, husband to the above-mentioned Alicia, was one of the judges who passed sentence on king Charles I. and also one of the lords commissioners of the great seal during the protectorate of Cromwell. On the eve of the restoration he fled to the continent, was proscribed by the parliament of Charles II., and assassinated at Laufanne, in Switzerland, by three villains, hired for that purpose by some of the royal family, or their friends. Beauties of England and Wales, vol. vi. by John Britton, F.S.A. and E. W. Brayley, Lond. 1805.

**RINGWORM**, in *Medicine*, a popular appellation, applied to various superficial affections of the skin, which assume somewhat of a circular form. But the fact is, that almost all the partial cutaneous diseases have more or less a tendency to the annular figure, and rise in somewhat irregular patches, approximating to the oval or the circle, which is sometimes perfect, and sometimes broken. It is only by referring to an intelligible nomenclature, such as that proposed by the late Dr. Willan, that any discrimination can be clearly made in the varieties of these eruptions. If we examine these ringworms according to this system, we shall find, that there are several diseases, to which the term is applicable, and daily applied, and consequently the same remedies recommended for their cure, which are, nevertheless, very different in their nature, and therefore require very different modes of treatment. Thus there is a circular eruption, which consists of patches of *pimples*, the lichen circumscriptus of Dr. Willan; even the *scaly* lepra occurs in circles of various sizes, and is sometimes called ringworm: the *pustular* disease, called impetigo figurata, or moist tetter, and the *vesicular* eruption termed herpes circinatus, (see Dr. Bateman's Pract. Synops. of Cutan. Diseases,) are also distinguished by their circular form, and it is to these two last that the term *ringworm* is most popularly applied. And above all, the contagious disease of the scalp, the porrigo scutulata, is so distinctly circular in its form, as to be distinguished from the other species of the same disorder, by the appellation of *ringworm*, or by some the *ringworm of the scalp*. See the same Synopsis, ord. v. gen. 2. See also PORRIGO, LICHEN, HERPES, &c. above.

The general treatment recommended for ringworms by the vulgar, is the application of common *ink*; and this, by its astringency, which is slight, may be partially useful in the decline of the *herpetic* ringworm, above-mentioned, or in the mildest forms of that of the scalp: but it will be certainly injurious if applied to the moist *tetter*, or to the *lichen* in its early stage; and the same effect can be produced by similar astringents, in a more manageable and less dirty form; as by solutions of the sulphate of iron or zinc in rose-water or other distilled water. But in fact, the ringworm of the scalp requires much more active remedies, on the one hand; and on the other, the herpetic ringworm disappears in a short time spontaneously; so that the remedy may be deemed in both cases useless. It is obvious, then, that diseases, which are pustular, scaly, vesicular, and papular respectively; some of which are inflamed, and others not; some contagious, and others not; some disappearing spontaneously, and others resisting the most active applications; some connected with disorder of the constitution, and

others

others merely local, cannot be treated with advantage, or even with impunity, by the same set of medicines, and ought not to be confounded under the same appellation; but particularly, the name of a disease is alone inquired for, and the remedy is appropriated to the name. By discarding the term ringworm, or uniting with it the epithets pustular, vesicular, or herpetic, porriginous, &c. this practical error may be avoided.

**RINLING, or AINLING**, in *Geography*, a town of Bavaria; 8 miles N.N.W. of Aicha.

**RINNE**, a river of Thuringia, which runs into the Saale, two miles below Rudelstadt.

**RINOREA**, in *Botany*, a name of uncertain derivation, but probably bestowed on this genus by Aublet, from its native appellation in Guiana.—Aubl. Guian. 235. Juss. 287. Lamarck Dict. v. 6. 211. Illustr. t. 134.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Berberides*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, villous, cleft into five, oblong, acute segments. Cor. Petals ten, concave, ovate, oblong; the five inner ones smaller; all inserted below the germen. Stam. Filaments five, short, inserted at the base of the outer petals; anthers oblong, two-celled, with two valves bursting from the base to the top. Pist. Germen superior, roundish, villous; style oblong, villous; stigma obtuse. Peric. unknown.

Obf. Jussieu describes *Rinorea* as having five longer petals, each furnished with an inner one at its claw or base.

Ess. Ch. Calyx five-cleft. Petals ten, the five inner ones smaller. Style one. Stigma one.

1. *R. guianensis*. Aubl. Guian. t. 93.—Native of cultivated ground in Guiana, where it flowered in January.—A tree six or seven feet high, whose trunk is branched very thickly, to the very summit, in a straight alternate manner. Leaves alternate, stalked, ovate-oblong, acute, toothed. Stipulas short, deciduous. Flowers white, in axillary, terminal clusters, each placed on a short stalk, which is furnished with two scales at its base.

**RINTELN**, in *Geography*, a town of Germany, in the county of Schauenburg, situated on the S. side of the Weser. The university of Stadthagen was removed to this town in the year 1621; its professors of divinity are Lutherans, but those of the other faculties are Calvinists. The town church belongs to the Lutherans; the Calvinists and garrisons use the university church for their service. The ramparts, ditches, and bulwarks, that environ the town, were begun in 1665, and finished in 1668. The inhabitants are chiefly employed in agriculture, breeding of cattle, and brewing; 9 miles S.S.E. of Minden. N. lat. 52° 11'. E. long. 9° 8'.

**RINUCCINI, OTTAVIO**, in *Biography*, an Italian poet of Florence, who went into France in the suite of Mary of Medicis, queen to Henry IV. He was the inventor of the musical drama or opera, that is, of the manner of writing or representing comedies or tragedies in music, to which the first recitative was applied. (See RECITATIVE.) Others give this invention to a Roman gentleman of the name of Emilio del Cavaliere, who was more properly the inventor of the sacred drama or oratorio, in a similar species of music or recitative, so nearly at the same time, that it is difficult to determine which was first: both had their beginning in 1600. See CAVALIERE, and ORATORIO.

It is certain that Rinuccini was author of three lyric pieces, "Daphne," "Euridice," and "Ariadne," which all Italy applauded. Euridice, written for the nuptials of Mary of Medicis, was first performed with great splendour

and magnificence at Florence, at the court and expence of the grand duke.

The poetry of Rinuccini is truly lyrical, smooth, polished, and mellifluous. He died in 1621, at Florence; and his works were published in 1622, in the same city, in 4to. by his son, Pietro Francesco Rinuccini. The family is noble, and was subsisting in 1770.

**RINVEEL POINT**, in *Geography*, a cape of Ireland, in the county of Galway, N. of Ballinakiel bay. N. lat. 53° 41'. E. long. 9° 58'.

**RINUM**, a town of Persia, in the province of Segestan or Seistan; 60 miles E.N.E. of Zareng.

**RIO de los Anzuolos**, a river of Mexico, which runs into the Spanish Main, N. lat. 11° 10'.—*R. dos Apostolos*, a river of North America, which runs into the northern part of the gulf of California.—*R. de Bogota*, a river of New Granada, which collects all the waters of the valley of Bogota, the bottom of which valley, according to Humboldt, is no less than 7460 feet above the level of the sea, and finds its way through the mountains to the S.W. of the town of Santa Fé. (See BOGOTA.) The perfect level of the plain, its geological structure, and the form of the rocks, which resemble small islands in the middle of the Savannas, appeared to M. Humboldt to indicate the existence of an ancient lake. If the single outlet of the river were to be stopped, the valley would again be converted into a lake. The river, where it leaves the valley, is about 144 feet wide, half the breadth nearly of the Seine at Paris, between the Louvre and the Palace of the Arts. It then enters into a narrow rocky channel, not more than 40 feet wide, which appears, says the same intelligent and instructive traveller, to have been formed by an earthquake. After running for a little way in this crevice, the river precipitates itself, at two bounds, to the depth of 574 feet. After this tremendous fall, it pursues its way to the Magdalena, about 50 miles, still descending with great rapidity, and at the rate of 150 feet to a mile. Although this is not the greatest fall in the globe, there is not probably any which, from so great a height, precipitates so large a body of water. Bouguer makes the height between 1500 and 2000 feet; but he speaks only from the information of others who had seen the fall, and pointed out to him such heights as they thought might be nearly equal to it. The accompaniments of this waterfall, upon which the effect so much depends, are an assemblage of every thing that is sublime, beautiful, and picturesque. Independent, says M. Humboldt, of the height and the size of the column of water, the figure of the landscape, and the aspect of the rocks; the peculiar character stamped on these great scenes of nature is owing to the luxuriant form of the trees and herbaceous plants, their distribution into groups, or into scattered thickets, the extent of the craggy precipice, and the freshness of vegetation. Another feature in the character of this extraordinary cataract is probably quite peculiar to it:—the water descends from a cold region to a warm one. The plain of Bogota, especially near the fall, is extremely fertile, and is supposed to owe some of its fruitfulness to the irrigation occasioned by the great quantity of water from the fall, which is dissolved in the air, and afterwards precipitated. The fine crops of wheat, the oak, the elm, and other plants, recall to mind the vegetation of Europe. Looking down from this terrace, one sees, with surprise, at the bottom, a country producing the palm, the banana, and the sugar-cane. This cannot arise from the difference of height; as it is known, that no very great change of temperature can be produced by a difference of level of 570 feet. M. Humboldt suggests, that it is probably owing to the shelter which

which the high country affords to the low. It is one of the circumstances that has added much to the marvellous height of the cataract; as the height is naturally supposed to be great, that carries one at once from the temperature of Europe, and one where the thermometer is sometimes at the freezing point, to that of the torrid zone. Although the river loses a great part of its water in falling, which is reduced into vapour, the rapidity of the lower current forces the observer to keep at the distance of 150 yards from the basin dug out by the fall. The solitude of the place, the richness of the vegetation, and the dreadful roar that strikes the ear, contribute to render the foot of the cataract of Tequendama one of the wildest scenes that can be found in the Cordilleras. (Humboldt's Researches, &c. translated by Helm M<sup>r</sup>Williams, Lond. 1814.)—*R. Bueno*, a river of the island of Jamaica, which runs into the sea on the north coast, N. lat. 18° 30'. W. long. 77° 19'.—*R. de Cedros*, a river of South America, which runs into the Pacific ocean, N. lat. 2° 30'.—*R. Cobre*, a river of Jamaica, which passes by Spanish Town, and runs into the sea, 4 miles N.W. of Kingston.—*R. del Conchos*, or *de Salinas*, a river of Mexico, which joins the Brava at its mouth.—*R. Dolce*, or *Fresh-water river*, a river of Brazil, which runs into the Atlantic, S. lat. 19° 20'.—*R. Dolce*, or *Dulce*, a river of South America, in the province of Tucuman, formed by the confluence of several rivers. After passing by St. Yago del Estero, &c. and pursuing a course of about 300 miles, it loses itself in a salt lake, S. lat. 30° 40'.—*R. de los Dorados*, a river of Mexico, which runs into the Spanish Main, N. lat. 9° 45'.—*R. dos Esmeraldas*, a river of America, on the isthmus of Darien, which runs into the Pacific ocean, N. lat. 2° 42'.—*R. dos Esmeraldas*, a river of Peru, which runs into the Pacific ocean, N. lat. 0° 57'.—*R. Frisco*, a river of Africa, which runs from the Ivory coast into the Atlantic, N. lat. 5° 8'. W. long. 5° 55'.—*R. dos Galinas*. See MAGUALBARI.—*R. Grande*, a river of South America, which runs into the Spanish Main, between Carthagena and St. Martha.—*Alfo*, a river of the island of Jamaica, which runs into the sea, on the N. coast, N. lat. 18° 15'. W. long. 76° 14'.—*R. Grande*, or *Ciudad Nova*, a town of Brazil, in the jurisdiction of Pernambuco, formerly the seat of a jurisdiction. S. lat. 5° 44'.—*R. Grande*, a river of Brazil, scarcely deserving the name, the mouth of which is situated in S. lat. 3° 2'.—*Alfo*, a river of Africa, which passes the coast of Zanguebar, and runs into the Indian sea, forming the islands of Patta and Lamo at its mouth. S. lat. 2° 5'. E. long. 41° 30'.—*Alfo*, a river of Africa, navigable for boats near 400 miles from the mouth, which lies on the Atlantic, N. lat. 11°. W. long. 14° 36'.—*Alfo*, a river of America, which rises in the isthmus of Darien, and runs into the Pacific ocean, three miles W. of Panama. See also VERMEJO, PATINA, and HACHA.—*R. Hondo*, a river of Yucatan, which runs into the bay of Honduras.

*Rio de Janeiro*, a jurisdiction or independent government of Brazil, so called by the Portuguese when they became masters of the country, from the river Janeiro, which runs through the middle of it; and the river probably derived its name from its having been discovered on the day of the feast of St. Januarius, or on the 11th day of January, in 1516, by Solis. The province and the river are called by the natives "Genabara." At the mouth of the river, on the east side, is the fort of Santa Cruz, and on the west, that of St. Jago, together with the capital. The rivers in this government are few, and none of them large, except the Janeiro, which is rather a salt bay or gulf than a river, and two rivers that discharge themselves into this bay. At the mouth of it are several small islands, that render its entrance

somewhat difficult and dangerous. Although the soil of this province is for the greatest part rich and fertile, the inhabitants manifest little industry either in the cultivation of the soil or the improvement of the country. It consists chiefly, at least near the capital, in raising garden vegetables for the whites, and rice and manioc for the blacks. Wheat is found to grow in other parts of the Brasils, with an increase beyond what is known in Europe. A corn-mill, distinguished by the simplicity of its structure, attracted the notice of sir George Staunton; and he has thought it worthy of being described. A wheel, a few feet only in diameter, was placed horizontally, much below the current of a stream, as it fell from a steep bank, and was received in hollows, 10 or 12 in number, so obliquely scolloped into the upper rim of the wheel, as to impel it to a quick rotatory motion, while its upright shaft, passing through an opening in the centre of an immoveable mill-stone above the wheel, but of a narrower diameter, was fixed to a smaller mill-stone, which, forced round with the motion of the wheel and dependent shaft, crushed between it and the larger stone beneath, the grain insinuated between them from a hopper. Thus that effect was produced by one wheel only, which is generally the result of a much more expensive and complicated machinery. A similar mill, it is said, is in use in the Crimea. A forest, not far from the capital, was found, by sir George and his associates, to abound in palms and mastic wood; also mango and gouyava trees are found growing to the size of trees, besides many other vegetables, never observed before by those who were then travelling through it. The ipecacuanha plant is said to grow at St. Catharine's within the government of Rio. The size and vivid hue of many of the flowers throughout the forest, and the gaudy plumage of the birds, which came occasionally in sight, were very striking. The woods, it is said, abound in snakes, some of which are extremely large and formidable. But their hissing noise puts those who hear it on their guard, and they seldom, without provocation, advance to an attack. The forest now mentioned led to the cultivated valley of "Tijouca," situated, as it were, in the bottom of a funnel, being surrounded on all sides by mountains, excepting to the southward, where a small opening admitted an arm of the sea. The valley was watered by a clear stream, which, upon first entering it, was precipitated down a steep and broad rock of granite, forming a magnificent cascade. Very little labour appeared necessary in the plantations of Tijouca. Indigo, manioc, coffee, cacao, and chocolate-trees, sugar-canes, plantains, and orange and lime trees, were commonly seen all growing promiscuously, and some spontaneously, in the space of 20 square yards. Coffee and indigo were the principal objects of attention. The temperature of the valley was excessively hot, on account of its confined situation, and the reflection of the sun's rays from the sides of the mountains, which in many places were very rocky. Fahrenheit's thermometer, about four in the afternoon, stood, in the shade, at 88°. Several districts of the government of Rio produced cotton, sugar, coffee, and cacao or chocolate, rice, pepper, and tobacco, in great abundance. That of Rio Grandé yielded plenty of excellent wheat. The vine grew in great perfection; but the grape is not suffered to be pressed for wine, as such a process might interfere with the sale of the same article from Portugal. But probably less caution may be exercised in this respect since the removal of the Portuguese government to the Brasils. Most of the land, as far as Cook and his companions had an opportunity of observing it, was laid down in grass, upon which cattle were pastured in great plenty; but they were so lean, that an Englishman would

scarcely eat their flesh: the herbage of these pastures consists chiefly of cresses, and consequently is so short, that though it may afford a bite for horses and sheep, it can hardly be grazed by horned cattle in a sufficient quantity for keeping them alive. For other particulars relating to the climate, productions, commerce, and inhabitants of this province, see *BRASIL*, and the next article.

*Rio de Janeiro*, a city of Brasil, and capital of the above-mentioned government, and also of the whole country, and the Portuguese dominions in America, situated on a river, or rather an arm of the sea, of the same name. Formerly *Bahia dos Todos*, or *Santos*, was the principal seat of government, and chief mart for commerce in the *Brasilis*; but the discovery and improvement of the gold and diamond mines, within about 100 leagues of *Rio de Janeiro*, and communicating immediately with it, gave a decided preponderancy to the latter. The city stands on a plain, close to the shore, on the W. side of the bay, at the foot of several high mountains which rise behind it. It is neither ill-designed nor ill-built; the houses in general are of stone, and two stories high; every house having, after the manner of the Portuguese, a little balcony before its windows, and a lattice of wood before the balcony. Its circuit was computed by lieutenant, afterwards captain, Cook, to be about three miles, and it appeared to be equal in size to the largest country towns of England, Bristol and Liverpool not excepted; the streets are straight, and conveniently broad, intersecting each other at right angles; most of them, however, lie in a line with the citadel, called *St. Sebastian*, which stands on the top of a hill, that commands the town. The harbour is safe and capacious, and very convenient for commerce. Captain Mackintosh, from experience, recommends to ships bound for this harbour, after getting in with *cape Frio*, instead of steering along shore, to shape their course between S.W. and S.W. by W. for 12 or 14 leagues. To this distance the land wind extends. The forenoon in general are calm, but almost every afternoon a fresh sea-breeze sets in from the S.W. It is proper to steer, in a direct course, from hence to the small islands lying under the great inclining *Sugar-loaf* on the western side of the entrance into *Rio* harbour. From these small islands the wind will carry the ship to the opposite side of the harbour's mouth, where the fort of *Santa Cruz* is situated, and which may be approached within 50 yards, and from thence, safely and quickly, into harbour. The entrance of the harbour, as *sr Erasmus Gower* observes, will shew itself by discovering the castle or fort of *Santa Cruz*, and a small fortified island, called *Fort Lucia*, nearly abreast of it. Between these is the channel into the harbour, near a mile wide; both shores are steep; that of *Santa Cruz* is perpendicular, there being six fathoms in the wash of the sea. The narrowness of the channel causes strong tides; but as the sea-breeze blows fresh, they do not impede entering into the harbour. In going in it is best to keep mid channel, or even nearer to *Santa Cruz*. About four miles outside the harbour's mouth, the depth of water is 18 and 19 fathoms, which will decrease gradually to 8 or 7; and this, being the shallowest part, may be called the bar, which is about two miles outside the fort. The water again deepens, on approaching to *Santa Cruz*, to 17 and 18 fathoms, nor will less be found in the fair way of the great road. Large ships may moor in shoaler water, but that depth, or thereabouts, is more advisable, as such a situation affords the full advantage of the sea-breeze, as well as that of avoiding the insects, which are very troublesome when nearer to the shore. In the inner harbour, formed by an island called "*Ilheo dos Cobras*," or *Serpent island*, are proper wharfs for heaving ships down by;

but the mode of doing it alongside hulks is now preferred. In the same harbour will ships anchor, which are loading or unloading goods, or want repairing; but the outer is the more healthy situation. *Rio* is situated in S. lat.  $22^{\circ} 54'$ , and W. long.  $42^{\circ} 44'$ . The variation of the compass is  $4^{\circ} 55'$  W. of the pole. The tide flows  $7\frac{1}{2}$  hours, and rises about  $5\frac{1}{2}$  feet perpendicular. Fahrenheit's thermometer, during *sr G. Staunton's* stay, was between  $77^{\circ}$  and  $82^{\circ}$ .

The entrance into the harbour, from the sea, is bounded, on one side, by the leaning cone already mentioned, measuring 700 feet in height, and by the huge mass of granite, supporting the castle of *Santa Cruz*, on the other; and is interrupted, near the middle, by the little island on which *Fort Lucia* is erected. On entering into the harbour it was found to enlarge to a width of three or four miles, and to penetrate, in several branches, farther than the eye could reach. It is interrupted with many islands, some entirely green, and some covered with batteries or habitations. The shores of the harbour were diversified and embellished with villages, farms, and plantations, separated by rivulets, ridges of the rocks, indentures of little sandy bays, or the skirts of a forest; the whole terminated, in distant prospect, by an amphitheatre or screen of mountains, rising in a vast variety of rude and fantastic forms, but covered with trees to their very summits.

Within four miles of the harbour's mouth is situated, on the W., the city of *St. Sebastian*, usually called *Rio*, built on a projecting tongue of land; but all the ground behind it is broken into hills and rocks, with woods, houses, convents, and churches on their tops. A convent of *Benedictines*, and also a fort commanding the town, are situated upon the extreme point jetting into the harbour; opposite to this point is *Serpent island*, between which and the town is a narrow channel, sufficiently deep, however, for the passage of the largest ships. Upon the island are, a dock-yard, magazines, and naval store-houses; and round its shores are the usual anchoring places for the shipping which frequent this port. Beyond the town the harbour begins to widen considerably, and resembles a large lake with many islands upon its surface. In the late improved state of the town, the streets are paved, with the addition of foot-paths, and though some of them are narrow, they are convenient in a hot climate by the shade which they afford. In the squares are refreshing fountains, which supply the water conveyed to them by an aqueduct of considerable length; a circumstance of moment, as *Rio* has no river close to it of any note. This aqueduct is carried over vallies by a double row of arches, one placed above another; and thus presents a structure that adds great ornament to the town. A guard constantly attends at the fountains throughout *Rio*, to regulate the distribution of the water, which is, probably, scanty, as there are people who wait a long time with buckets for their share. A sufficient proportion of the water from the fountain upon the quay opposite to the palace, is allotted for the use of the shipping, and is conveyed to the casks, remaining in the boat, by means of a woollen or canvas tube, called a hose, stretching from the fountain to the cask. *Capt. Cook* complained that the water was not good; but this circumstance *sr Erasmus Gower* ascribes to some accidental impurities that must have remained in the casks which he filled with it.

The shops of *Rio*, says *Staunton*, were full of *Manchester* manufactures, and other British goods, even to English prints, both serious and caricature. A Portuguese merchant advertising to these supplies of goods, and the advantages gained by the country that furnished them, observed that the prosperity both of *Portugal* and its dependencies redounded

redounded chiefly to the benefit of England. The benefit has probably been reciprocal; and, it is hoped, will thus continue. The exterior appearance of the inhabitants indicated ease and comfort; their dwellings were generally in good condition, many of them large, and well adapted to the climate; the magazines and markets well stored with merchandize; new buildings, private and public, erected; tradefinen busily employed; and besides the aqueduct and fountains, which adorned the city, it had some public walks, and a spacious quay of granite, of which material, found upon the spot, many of the chief edifices were constructed. The place, however, is said to be unhealthy; and instances of longevity are rare. This insalubrity may be owing, perhaps, to local and temporary circumstances, more than to the necessary influence of the climate. The situation of the town upon a plain, almost wholly surrounded by hills thickly covered with forest trees, deprives it of a free circulation of air, and exposes it to the morning and evening damps of humid nights, preceded by scorching days, and of course putrid and intermitting fevers mult often be the consequence. Water is also suffered to stagnate in marshes near the town; and to these disadvantages we may add the tormenting influence of infinite swarms of musquitoes, or large gnats, which attack strangers for some time after their arrival. But none of these real, or any imaginary, evils restrain the propensity of all classes of society towards gaiety and pleasures. See BRASIL.

The inhabitants of Rio are very numerous, and consist of Portuguese, Negroes, and Indians, the original natives of the country. This township, which is but a small part of the capitanea, or province, is said, according to Cook, to contain 37,000 white persons, and 629,000 blacks, many of whom are free, amounting together to 666,000, in the proportion of 17 to 1. The Indians, who are employed to do the king's work in this neighbourhood, can scarcely be considered as inhabitants; their residence is at a distance, from whence they come by turns to their task, which they are obliged to perform for a small pay. The guard-boat was constantly rowed by these people, who are of a light copper colour, and have long black hair. See BRASIL.

When walking abroad, men of the lower classes generally wear cloaks; and those of the middling and higher ranks never appear without swords. The ladies wear their hair hanging down in tresses, tied with ribbands, and adorned with flowers; their heads being uncovered. In their visits to the churches, both at matins and vespers, they are regular; at other times they are generally seated at their windows or balconies. Many of them have fine dark eyes, with animated countenances. In the evenings they amuse themselves by playing on some kind of musical instrument, chiefly the harpsichord or guitar. At this time the doors and windows are thrown open for the admission of cool air. If a stranger should happen to stop to hear the music, it often happens that the father, husband, or brother of the lady that is playing, steps out and politely invites him into the house; and the ladies, not unfrequently, having bunches of flowers in their hands, exchange them with gentlemen as they pass by. This practice may perhaps be an imitation of that of the ladies of Lisbon, who on particular days, called "days of intrusion," throw nosegays from their balconies upon persons walking under them. Captain Cook charges the same indelicate want of reserve on the ladies of Rio; but we trust the accusation which some persons have brought against them, that there is not one modest woman among them, is not only too general, but founded on a misrepresentation of what they may conceive to be an allowable practice, founded in custom and courtesy. Some of the

men, however, have been accused of much worse practices, in yielding to depraved and unnatural appetites.

Among the more innocent pleasures of both sexes are operas, plays, and masquerades. Company often assembles at a garden, situated near the sea, at one extremity of the town, and laid out in grass plats, shrubberies, and parterres, ornamented in various ways. In these recesses the gay society of Rio, after taking the exercise of walking in the evening, and after hearing songs and music, sit down to partake of banquets, occasionally accompanied by music and fire-works. On the side of this garden next the sea is a terrace, and at the extremities of the terrace there are two neat square buildings, like English summer-houses. In one the walls are decorated with paintings, representing views of the harbour, and particularly of the whale-fishery, which was formerly carried on in it; until the large black whale, which formerly frequented it, was disturbed and driven away, in consequence of the increased concourse of shipping. The cycling of this and the other summer-house are covered with various appropriate devices, in shell or feather work; and the walls of the latter are decorated with eight large paintings, descriptive of the principal productions to which the country is indebted for its opulence, including views of the diamond and gold mines, with the operations performed in them; of the cultivation of the sugar-cane, and the processes by which its juice is extracted and granulated into sugar; of the manner of collecting the small animals which produce the cochineal, and preparing the rich dye from them; of the culture of the manioc, with the process of making cassada and tapioca; and of the culture and preparation of coffee, rice, and indigo. Near the town is another garden, originally intended for promoting the progress of botany, but now chiefly curious for a small manufacture of cochineal; but the garden at Rio does not produce annually above 30 pounds of this commodity. The preparation of cochineal, however, is now encouraged by the trade being laid open, which was formerly a monopoly to the crown. Another species of manufacture is carried on in the vicinity of Rio; an exclusive privilege having been given to a company, upon paying one-fifth of its profits to the crown. To this harbour was brought, for the purpose of converting it into oil, the blubber or firm fat of the black whales. The whale-bone or cartilages of the jaw were also properly separated and cleaned here, before they were sent to Europe. In another part of the harbour of Rio, called Val Lengo, are warehouses for the reception and sale of slaves. See BRASIL.

The establishment for the defence of Rio consists of two squadrons of cavalry, two regiments of artillery, six regiments of infantry, two battalions of disciplined militia, beside above 200 disciplined free Negroes; making, in the whole, a body of at least 10,000 men, exclusively of a very numerous registered but undisciplined militia, of whom a considerable proportion is in the city and its neighbourhood. The entrance of the harbour, which is scarcely a mile from point to point, is crossed in every direction by heavy batteries. The fort of Santa Cruz is a work of some strength, and the principal defence of the harbour. But the defence of the city of Rio is supposed to depend chiefly on the works erected on the Serpent island, which is about 300 yards long; it mounts 46 guns, 20 facing the south and south-east, and the remainder looking to the opposite points. The parapet, along the front of the town, recently constructed, will afford a good line for musquetry and light guns.

The high conical rocks at the entrance of the harbour of Rio, and the surrounding hills, are all of granite, in which

the only remarkable circumstance is the large proportion of feld-spath contained in it. About two miles within the harbour, on the south-west side, is one high rock, entirely composed of columnar masses, bearing the resemblance of basaltes: it rests upon clay. In all the quarries of granite it is found incumbent upon clay and sand. Here are three species of granite: the first, red-coloured, soft, and shining; the second, deep blue coloured, harder, and of a closer texture; and the third of a whitish shining colour, containing much mica, and little feld-spath; its texture soft, and incapable of a good polish.

The government of Rio is, as to its form, mixed; and yet, in fact, very despotic. It consists (we are now speaking of its state before the removal of the Portuguese government thither) of the viceroy, the governor of the town, and a council. To restrain the people from travelling into the country, and penetrating into any district where gold or diamonds may be found, certain bounds are prescribed to them, at the discretion of the viceroy, sometimes at a few, and sometimes at many, miles distance from the city. On the verge of these limits a guard constantly patrols, and any person that goes beyond it is seized and thrown into prison.

The riches of this place consist chiefly in the mines, that lie at a considerable distance in the country, from which much gold is brought, at the expence of many lives. Precious stones are also found here in such plenty, that a certain quantity only is allowed to be collected in a year: they are diamonds, topazes of several kinds, and amethysts. The mines called "general" are the nearest to the city, at the distance, according to the statement of M. Bougainville, in his account of his voyage round the world, of about 75 leagues. They yield to the king every year, for his right of fifths, at least 112 arrobas of gold: in 1762 they yielded 119. Under the captaincy, the *MINAES Geraes* (which see) are comprehended those of Rio de Morte, of Sabara, and of Serro-frio. The last, besides gold, produces all the diamonds that come from Brasil. They are found at the bottom of a river, of which they turn the course, in order to separate from the pebbles in its bed the diamonds, topazes, chrysolites, and other stones of inferior quality. Of all these stones, the diamonds alone are contraband: they belong to the undertakers, who are obliged to give an exact account of the diamonds found, and to place them in the hands of the intendant appointed by the king for this purpose, who deposits them immediately in a casket encircled with iron, and shut with three locks. He has one of the keys, the viceroy another, and the assayer of the royal treasury the third. This casket is enclosed in a second, sealed by the three persons above-mentioned, and which contains the three keys of the first. The viceroy has not the power of visiting its contents: he only consigns the whole to a third strong coffer, which he sends to Lisbon, after having set his seal on the lock. They are opened in the presence of the king, who chooses what diamonds he pleases, and pays the price to the undertakers at the rate fixed by their agreement. The undertakers pay to his most faithful majesty the value of a piastre Spanish money, for every slave employed in searching for diamonds; and the number of these slaves may amount to 800. Of all kinds of contraband trade, that of diamonds is the most severely punished.

The gold drawn from the mines cannot be carried to Rio de Janeiro, without being first brought to the smelting houses established in each district, where the right of the crown is received. What remains to private persons is remitted in bars, with their weight, number, and the royal arms.

Those bars belonging to individuals are registered in the factory of La Prayburia, 30 leagues from Rio de Janeiro. In this station are a captain, lieutenant, and 50 men; here is paid the right of fifths; and, besides, a toll of a real and a half *per head* on men, cattle, and beasts of burthen. Half of the product of this duty belongs to the king, and the other half is divided between the detachment according to rank. As it is impossible to return from the mines without passing by this office, all persons are there stopped, and searched with the greatest severity. Individuals are afterwards obliged to carry all the gold in bars, which belongs to them, to the mint of Rio de Janeiro, where the value is given in coin, commonly in half doubloons, each worth eight Spanish dollars. Upon each of these half doubloons the king gains a dollar, by the alloy and the right of coinage. The mint of Rio Janeiro is one of the most beautiful which exist; it is furnished with every convenience to work with the greatest celerity. As the gold arrives from the mines at the same time that the fleets arrive from Portugal, it is necessary to accelerate the work of the mint, and the coinage proceeds with surprising quickness. The arrival of these fleets renders the commerce of Rio Janeiro very flourishing, but chiefly that of the Lisbon fleet. The mines of St. Paolo and Parnaqua yield to the king four arrobas for the fifths every year. The most distant mines, as those of Pracaton and Quiaba (Cuyaba), depend on the captaincy of Matogrosso. The fifth of the above mines is not received at Rio Janeiro, but that of the mines of Goyas is deducted. This captaincy also possesses diamond mines, the working of which is prohibited.

The whole of the expence of the king of Portugal at Rio Janeiro, for the payment of the troops and civil officers, and for the charges of the mines, the maintenance of the public buildings, the careening of vessels, amounts to about 600,000 dollars. The expences of building ships of the line and frigates there stationed are not included.

Recapitulation, and Amount of the Average of different Objects of royal Revenue.

	Dollars.
150 arrobas of gold, the average produced by the royal fifths, are in Spanish money	- 1,125,000
The duty on diamonds	- 240,000
The duty on coinage	- 400,000
Ten <i>per cent.</i> from the custom-house	- 350,000
Two and a half <i>per cent.</i> of free gift	- 87,000
Right of toll, sale of employments, officers, and generally all the profits of the mines	- 225,000
Duty on slaves	- 110,000
Duty on fish-oil, salt, soap, and the tenth on the provisions of the country	- 130,000
Total	<u>2,667,000</u>

From which, deducting the above expences, it will appear that the king of Portugal draws from Rio Janeiro a revenue exceeding 10,000,000 of French livres, or 416,666*l.*

The coin that is current here, is either that of Portugal, consisting chiefly of 36*s.* pieces, or pieces both of gold and silver, which are struck at this place: the pieces of silver, which are very much debased, are called patacks, and are of different value, being easily distinguished by the number of rees marked on the outside. Here is also a copper coin, like that in Portugal, of five and ten ree pieces. See REE.

Upon the whole, Rio de Janeiro is a very good place for ships to put in at that want refreshment: the harbour is safe and commodious; and provisions, except wheat bread and flour, may be easily procured: as a succedaneum for bread, here

here are yams and cassada in plenty: beef, both fresh and jerked, may be bought, says Cook in 1768, at about  $2\frac{1}{4}d$ . a pound, but it is very lean. The people here jerk their beef by taking out the bones, cutting it into large but thin slices, then curing it with salt, and drying it in the shade: it eats very well, and if kept dry, will remain good a long time at sea. Mutton is scarcely to be procured, and hogs, and poultry, are dear. Of garden-stuff and fruit there is abundance; but none can be kept at sea except the pumpkin: rum, sugar, and molasses, all excellent in their kind, may be had at a reasonable price; tobacco is also cheap, but not good. Cook's Voyages by Hawkeſworth, vol. ii. Staunton's Embaſſy, vol. i.

Rio Infanta. See Great FISH river.

Rio de Limones, a river of the island of Cuba, which runs into the Spanish Main, N. lat.  $20^{\circ} 21'$ . W. long.  $78^{\circ}$ .—R. Mino, a river of Jamaica, which runs into the sea, on the W. side of Carlisle bay.

Rio das Mortes, a town of Brazil, in the jurisdiction of Minaes Geraes, situated on a river of the same name, which runs into the Parana.

Rio Negro, a considerable river of South America, which runs from the river Oronoko, in the kingdom of Granada, and enters the river of the Amazons, near Fort Rio Negro. S. lat.  $3^{\circ} 15'$ . W. long.  $61^{\circ} 31'$ .—R. Nuevo Bay, a bay on the N. coast of Jamaica. N. lat.  $18^{\circ} 26'$ . W. long.  $76^{\circ} 46'$ .—R. de Oro, a river of the island of Chiloe, which runs into the Pacific ocean, S. lat.  $42^{\circ} 45'$ .—R. de Ouro, a river of Africa, which runs into the Atlantic, N. lat.  $23^{\circ} 52'$ . W. long.  $16^{\circ}$ .—R. de las Palmas. See PALMAS.—R. das Palmas. See SCHERBRO.—R. de la Plata. See PLATA.—R. des Patos, a river of Brazil, which runs into the Atlantic, S. lat.  $28^{\circ} 30'$ .—R. des Pedras, a river of Africa, which runs into the Atlantic, N. lat.  $9^{\circ} 10'$ .—R. de Pinos, a river of the Isthmus of Darien, which runs into the Spanish Main, N. lat.  $9^{\circ} 12'$ . W. long.  $80^{\circ} 25'$ .—R. de Puercos, a harbour on the N. coast of Cuba, S.W. of Bahia Honda.—R. de los Rabados, a river of Chili, which runs into the Pacific ocean, S. lat.  $45^{\circ} 10'$ .—R. dos Ramos, a river of Africa, which runs into the Atlantic, S. lat.  $14^{\circ} 37'$ .—R. Real, a river of Brazil, which divides the captainship of Serrippe from that of All-Saints. This river, if it were not for the bar at the entrance, on which there is but ten feet of water, would be an inlet to the most fertile and pleafant part of the Brasils. Over the bar there is room enough, and depth of water sufficient, for the whole navy of England to ride in safety. About four leagues above the mouth, this river divides itself into four large branches, one running N.N.W. called Rio Fundo, another N.W. navigable for any vessel that can get near the bar, as far as the towns of St. Lucia and St. Eustatia, from the latter of which it takes its name, a third, called Rio de Pao Grand, or Great Timber river, which runs W.N.W. The main branch, which runs W.S.W. is also navigable as far as the town of Bahia, about 20 leagues from its mouth. On the banks of these branches there are many fine plantations, and small villages, which send great quantities of sugar, tobacco, and mandioc to Bahia or Fernambuco, as the wind permits. This river runs into the sea through four channels, formed by three small sandy islands, lying in the mouth of it. About 12 leagues to the S. of Rio Real is a small harbour, called Torre Garcia de Avilla, defended by four pieces of cannon; the town lies about a mile above the port, on the highest land on this coast; and it is the best for a ship to make, that is bound to Bahia, while the N.E. wind blows.—R. del Rey, or River Real, a river of Africa, which runs into the At-

lantic, N. lat.  $4^{\circ} 30'$ . E. long.  $8^{\circ} 5'$ . This river may be distinguished by the extreme high lands of Amboyes, between it and the river Camarones, situated S.E. from the mouth. It appears like a deep large bay running N., 21 or 24 miles wide at the entrance, where the ground is oozy; the channel being exactly in the middle, free from shoals and sands, except near the E. side, which is foul; the shore on both sides is low and marshy. The river which comes far from the N., is wide for a long interval into the country, and receives several considerable rivers in its course: the adjacent lands are populous and full of villages. The principal trade consists in slaves and large elephants' teeth, and akkori or blue coral. The inhabitants are called Calbongas (which see).—R. dos Reyes Magos, a river of Brazil, which runs into the Atlantic, S. lat.  $19^{\circ} 20'$ .—R. St. Balarido, a river of New Albion, which runs into the Pacific ocean, N. lat.  $34^{\circ} 44'$ .—R. St. Andre, a river of Chili, which runs into the Pacific ocean, S. lat.  $35^{\circ} 40'$ .—R. St. Maria, a river of Chili, which runs into the Pacific ocean, S. lat.  $51^{\circ} 36'$ .—R. de Sal, a river of Mexico, which rises in the province of Culiacan, on the borders of New Biscay, and runs into the Pacific ocean, N. lat.  $23^{\circ} 40'$ .—R. Salado, a river of South America, in the province of Tucuman, which rises about 60 miles W. of Salta, and first bears the name of "Rio del Passage," but being joined by several smaller streams, it changes its name to Salado, and runs into the Parana at Santa Fé, in the province of Buenos Ayres; its whole course being about 500 miles.—R. Salado, or R. des Apaches, a river of North America, one of the branches of the river Bravo, which joins the main stream, about N. lat.  $30^{\circ} 40'$ . W. long.  $86^{\circ}$ .—R. Salado, a river of South America, which in the latter part of its course, divides Chili from Peru, and runs into the Pacific ocean, S. lat.  $26^{\circ} 15'$ .—R. de los Sauces, a river of South America, which rises in Patagonia, and runs into the Atlantic by two streams, forming between them a considerable island and the southern mouth of the bay of Aneгада, S. lat.  $39^{\circ} 45'$ .

Rio Seco, a town of Portugal, in the province of Beira, on the borders of Spain; 7 miles S.S.E. of Almeida.—R. Seco, a river of Peru, which runs into the Pacific ocean, S. lat.  $7^{\circ} 6'$ .

Rio Secundo, a town of South America, in the province of Cordova, on the river Secundo; 30 miles S. of Cordova.—R. Selbota. See SCHERBRO.—R. Sin Fondo, a river of Chili, which runs into the Pacific ocean, S. lat.  $43^{\circ} 50'$ .—R. del Spiritu Santo. See MANICA.—R. das Trombetas, a river of Brazil, which runs into the river of the Amazons at Pauxi.—R. de Vacas, a river of Mexico, which runs into the Pacific ocean, N. lat.  $14^{\circ}$ .—R. Verde, a river of Peru, which runs into the Pacific ocean, N. lat. 1.

Rio Verde, a town of Mexico, in the province of Guaftea; 90 miles N.W. of St. Yago de los Valles.

RIOBAMBA, a jurisdiction of South America, in the vicerealty of New Granada and audience of Quito; situated to the south of the asiento of Latacunga. This jurisdiction is divided into two departments; the corregidor, who resides at Riobamba, appointing a deputy, who lives at the asiento of Hambato, situated between the capital and Latacunga. The first department contains 18 principal villages. The productions and manufactures of the province of Riobamba excel all the rest of the provinces of Peru. In various parts it has rich mines of gold and silver. The jurisdictions of Riobamba, Alausi, and Cuença, by means of the warehouses at Yaguache and Noraujel, carry on a considerable trade with Guayaquil. This trade, in the manufactures of the country, which consist only of three forts, cloth,

cloth, bags, and linen, is attended with considerable profit to the dealers, and advantage to the country, as all the poor people, who are remarkably numerous, and persons of substance, except those of the capital, wear the goods manufactured in the country. Part of the wheat produced in the jurisdiction of Riobamba and Chimbo is sent to Guayaquil. This jurisdiction is (by mistake) described under *Hambato* (which see). We shall here subjoin an account of *Hambato*. This assiento stands in a wide plain at the bottom of a mountain, N. of Riobamba. On its N. side runs a large river, which has a bridge; the river having never been fordable on account of its depth and extreme rapidity. It is finely situated, and in extent of populousness nearly equal to Latacunga; the number of its inhabitants amounting to eight or nine thousand. The houses are built of unburnt bricks, well planned, and make a good appearance. They are of low elevation, for the purpose of avoiding the destructive effects of earthquakes. Here are a parish church, two chapels of ease, and a convent of Franciscans. The earthquake which made such terrible havoc in the assiento of Latacunga proved also fatal to this, the horrors of which were augmented by the terrible eruptions from mount Carguarifo, in consequence of which a muddy torrent, formed of ashes, cinders, and snow melted by the flames of the aperture, precipitated down the sides of the mountain, overflowing the fields, sweeping away the cattle, and every thing else in the way by its violence. The inhabitants, in their manners and customs, resemble those of Quero; but it has fewer families of distinction than Riobamba. The bread made at this assiento is famous all over the province, and accordingly it is sent to Quito and other parts, without being deteriorated by length of time. It has six villages. The Indian inhabitants of the village of Quero make all sorts of cabinet work; that of Petate is equally famous for abundance of sugar-canes and the excellent quality of its sugar; and that of Santa Rosa de Pilaguin, which, with its fields, lies on the side of Carguarifo, is famous for the goodness of its barley, as the district bordering on the assiento is for its exquisite fruits; and to this district Quito owes most of the European kinds sold in that city. See QUITO and GRANADA.

RIOBAMBA, the capital of the jurisdiction above-mentioned, and described under *HAMBATO*. This elegant town, by the devastation occasioned by the terrible earthquake on the 4th of February 1797, became a heap of ruins, and soon totally disappeared; for the peak of Sicalpa falling on the town, and flopping the two rivers which pass by it, formed a lake, so that even the ruins were not visible. Of 9000 inhabitants, only about 400 escaped. Although Quito sustained little damage, Latacunga, and all the hamlets in its corregimiento, were utterly destroyed. Many persons perished, and the survivors were infected by the putridity of the dead bodies. Near *Hambato* many mountains split, and by their sudden fall occasioned still more awful destruction among the human race. Quero, mentioned in the preceding article, with all its people were buried, in an instant, under a cliff which fell on the town. Pelileo was overwhelmed by a stream of water and mud; the circumjacent lands were all transposed; and a deadly silence indicated the general ruin. Alausi and Guaranda also suffered greatly. The fate of Cuenca, Loja, Jaen, and Guayaquil, was, at that time, unknown; but the shocks do not seem to have extended so far. The cause of this desolation seems to have proceeded from the volcano Tangarunga or Tangurugua, between Latacunga and Riobamba; as the tremendous subterraneous thunders all proceeded from

that quarter, and the greatest ruin was in its vicinity; towards the N. the earthquake was faintly perceived at Pafto. Riobamba is distant 90 miles S. from Quito. S. lat.  $1^{\circ} 20'$ . W. long.  $78^{\circ} 30'$ . See QUITO.

RIOCHICO, a town of New Mexico, in the province of Hiaqui, on the river Hiaqui; 800 miles N.W. of Mexico. N. lat.  $29^{\circ} 4'$ . W. long.  $111^{\circ} 36'$ .

RIOFRIO, a town of Spain, in Old Castile; seven miles S. of Segovia.

RIOJA, a town of South America, in the province of Tucuman; 240 miles W.S.W. of St. Yago del Estero. N. lat.  $29^{\circ} 15'$ . W. long.  $70^{\circ}$ .

RIOLAN, JOHN, in *Biography*, an able French physician, was born at Amiens. He was greatly distinguished by his attainments both in literature and science, and is said not only to have written and spoken the learned languages with facility, but to have been thoroughly intimate with the contents of almost all the writings of the ancients. He gave lessons in natural philosophy at the college of Boncour, at Paris, where he took his degree in the year 1574. Little is recorded respecting his life, but that he was elected dean of the faculty in 1586, and continued in that office in the following year. He died on the 18th of October 1606. He was one of the greatest ornaments of the profession at Paris in his time; and was a strenuous advocate for the doctrine of Hippocrates and the ancients, whom he defended with great ardour against the chemists. His works are indicative of genius; they were collected and published, together with some posthumous tracts, at Paris, in 1610, under the title of "Opera Omnia." Separately, we find the following; "De Primis Principiis Rerum Naturalium, Libri tres." Paris, 1571. "Ad Impudentiam quorundam Chirurgorum, qui Medicis æquare et Chirurgiam publicè profiteri volunt; pro veteri dignitate Medicinæ Apologia philosophica," ib. 1577. This was a sort of declaration of war against the surgeons, whom he attacked for attempting to teach without any knowledge of literature; it was followed by several pieces on both sides. "Commentarii in sex posteriores Physiologiæ Fernellii Libros," 1577. "Ars bene Medendi," Lugd. 1589. "Ad Libros Fernellii de abditis rerum causis Commentarii," Par. 1598. "Univerſæ Medicinæ Compendium," 1598. "Ad Libavii Maniam Responſio, pro Censura Scholæ Parisiensis contra Alchymiam latâ," 1600. "Chirurgia," Lips. 1601. "Prælectiones in Libros Physiologicos et de abditis rerum causis. Accesserunt Opuscula quædam Philosophica," 1602. "De Febribus," 1640.

RIOLAN, JOHN, the son of the preceding, was born at Paris in the year 1577. His father did not fail to afford every encouragement and opportunity for the cultivation of his rising talents, and his mind was naturally turned to the study of medicine by the reputation, zeal, and love of the profession, which the former possessed; his early studies were also greatly facilitated, and many difficulties removed, by the domestic instruction which he thus received. His progress accordingly was uncommonly rapid; and a very few years after he had received his degree in 1604, he came forward as an author in a way that laid the foundation of his subsequent reputation. In 1613 he was appointed royal professor of anatomy and botany by Louis XIII.; and in this latter capacity he petitioned the king for the establishment of a botanic garden in the university of Paris. He subsequently held the appointment of physician to queen Mary de Medicis, and accompanied that princess in her travels; he arrived at Cologne, after her death, in July 1642, and returned to Paris, where he resumed the practice of

of his profession. After having twice undergone the operation of lithotomy, he lived to the age of eighty years, and died at Paris in February 1657.

Riolan was devoted to the study of anatomy, and was one of the most expert and learned anatomists of his time; his learning, indeed, was rather an obstacle in the way of his progress as a discoverer, or perhaps we should say his devotion to the ancients; for, in many cases, he seemed to see only through their eyes. Yet he was arrogant in his claims to originality, and by his pertinacity and sarcastic contempt of others, he raised himself many opponents and enemies. He published several original observations, however, respecting many parts of anatomical science, especially respecting the structure of the colon, the biliary ducts, the uterus and vagina, the tongue, os hyoides, &c. None of his anatomical works contain any engravings; as he maintained that no representations could supersede the study of nature. All his studies, however, were not confined to anatomy, as the following list of his works will evince. "Brevis excursus in Battologiam Quercetani, quo Alchemie principia funditus diruuntur, et Artis veritas demonstratur," Par. 1604. "Comparatio veteris Medicinæ cum nova, Hippocraticæ in Hermetica, Dogmaticæ cum Spagyrica," 1605. "Disputatio de Monstro Lutetiæ 1605 nato." "Incurfionum Quercetani depulſio," id. "Censura demonstrationis Harveti pro veritate Alchymicæ," 1606. "Schola Anatomica novis et raris observationibus illustrata. Adjuncta est accurata fœtus humani historia," 1607; enlarged by the author with the title of "Anatome corporis humani," 1610. "In Librum Cl. Galeni de Offibus, ad Tyrones explanationes apologetica pro Galeno, adversus novitios et novatores Anatomicos," 1613. "Gigantomachie," 1613, written in refutation of Habieot's account of the discovery of the bones of the giant Teuto-bochus. Riolan published two other tracts, or more, upon this controversy, which ended with the appearance of his "Gigantologie; discours sur la grandeur des Géants, &c." in 1618. "Osteologia ex veterum et recentiorum præceptis descripta," 1614. "Discours sur les Hermaphrodites, où il est démontré, contre l'opinion commune, qu'il n'y a point de vrais Hermaphrodites," 1614. "Anatomica, seu Anthropographia," 1618. "Enchiridium anatomicum et pathologicum," 1648, and many times reprinted; the best edition is of Paris, 1658. "Opuscula anatomica nova," Lond. 1649, containing remarks on the anatomical works of the most celebrated physicians, and an attack upon Harvey, and his doctrine of the circulation, of which Riolan was a great antagonist. "Curieuses Recherches sur les écoles de Médecine de Paris et de Montpellier," 1651. He also published three different works, entitled "Opuscula anatomica," in 1650, and the three following years, opposing the doctrines of Bartholine and Pecquet, respecting the absorbents and lacteals, and Harvey's on the circulation; and two more on the same subjects, with the titles of "Responsio prima, et altera," 1652 and 1655. Eloy Dict. Hist. de la Med.

RIOLI, in *Geography*, a town of Naples, in Capitanata; 11 miles S. of Manfredonia.

RIOLO, a town of Italy, in the department of the Amone; nine miles W. of Faenza.

RIOM, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Mauriac; 15 miles E.N.E. of Mauriac. The place contains 714, and the canton 7498 inhabitants, on a territory of 210 kilometres, in 12 communes.

RIOM, a town of France, and principal place of a district, in the department of the Puy-de-Dôme; eight miles N. of

Clermont-Ferrand. The place contains 13,328 inhabitants in both its E. and W. divisions; the canton of the former includes 12,433, and the latter 12,441 inhabitants; the territory of the former being 70, and that of the latter 24½ kilometres, the former having seven, and the latter five, communes. N. lat. 45° 43'. E. long. 3° 11'.

RIONDO, in *Ichthyology*, a name used by some for the fish more commonly called *aper*, a small fish, of the shape of the faber or doree, caught in the Mediterranean.

RIONE, or RIONI, in *Geography*, a river of Asia, anciently called "Phasis," which rises in the principality of Georgia, and forming the southern boundary of Mingrelia, runs into the Black sea, N. lat. 42° 15'. E. long. 41° 25'.

RIONS, a town of France, in the department of the Gironde; three miles N.W. of Cadillac.

RIOPA, a town of Spain, in New Castile; 13 miles S. of Alcaraz.

RIOS, a town of France, in the department of the Upper Saone, and chief place of a canton, in the district of Vefoul. The place contains 578, and the canton 9028 inhabitants, on a territory of 230 kilometres, in 34 communes.

Rios, a town of Chili; 90 miles N.N.E. of Valparaiso.

RIOSECO, a town of Spain, in the province of Leon; 96 miles N.N.W. of Madrid. N. lat. 41° 52'. W. long. 5° 7'.

RIOT, in *Law*, the forcible doing of an unlawful thing, of a private nature, by three or more persons assembled together for that purpose; either with or without a common cause or quarrel (3 Inst. 176.): as if they beat a man; or hunt and kill game in another's park, chase, warren, or liberty; or do any other unlawful act with force and violence; or even do a lawful act, as removing a nuisance, in a violent and tumultuous manner.

The word is formed from the Latin *riota*, of *arietare*, to run at each other as rams do. Though, from an ancient Gaulish version of the bible, quoted by Skinner, *riot* should rather seem originally to signify luxury and excess; whence our law *riot* might proceed; because these are frequently attended with quarrels.

For the difference between a riot, rout, and unlawful assembly, see *ROUT*, and *UNLAWFUL Assembly*.

The punishment of riots and routs, where a number of persons from three to eleven are concerned, is, by the common law, fine and imprisonment only; to which, in very enormous cases, the pillory has been sometimes superadded. (1 Hawk. P.C. 159.) And by the stat. 13 Hen. IV. c. 7. any two justices, together with the sheriff or under-sheriff of the county, may come with the posse comitatus, if need be, and suppress any such riot, assembly, or rout, arrest the rioters, and record upon the spot the nature and circumstances of the whole transaction; which record alone shall be a sufficient conviction of the offenders; and it is held that any battery, wounding, or killing the rioters, that may happen in suppressing the riot, is justifiable. The riotous assembling of twelve persons or more, and not dispersing upon proclamation, was first made high treason by stat. 3 & 4 Edward VI. c. 5. but repealed by stat. 1 Mary, c. 1. Nevertheless, the offence was made a single felony by 1 Mar. stat. 2. c. 12. and by 1 Eliz. c. 16. with whom the law expired. However, it was revived, in order to support the execution of the act of settlement, and made perpetual by 1 Geo. I. c. 5. which enacts, that if any twelve persons are unlawfully assembled to the disturbance of the peace, and any one justice of the peace, sheriff, under-sheriff, or mayor of a town, shall think proper

proper to command them by proclamation to disperse, if they contemn his orders, and continue together for one hour afterwards, such contempt shall be felony, without benefit of clergy. And farther, if the reading of the proclamation be by force opposed, or in any manner wilfully hindered, such opposers and hinderers are felons, without benefit of clergy; and all persons concerned, knowing of such hindrance, and not dispersing, are felons, without benefit of clergy. And the act indemnifies the peace officers, and their assistants, if they kill any of the mob in endeavouring to disperse them. Moreover, if any persons, so riotously assembled, begin, even before proclamation, to pull down any church, chapel, meeting-house, dwelling-house, or out-houses, they shall be felons, without benefit of clergy. Blackst. Comm. book iv. ch. xi.

**RIOU**, in *Geography*, a small island in the Mediterranean, near the coast of France. N. lat.  $43^{\circ} 11'$ . E. long.  $6^{\circ} 25'$ .

**RIOU'S Island**, or *Rovaboga*, an island in the Pacific ocean, about 24 miles in circumference; discovered in the year 1792, by lieutenant Herget, commander of the *Dædalus* storeship. S. lat.  $8^{\circ} 50'$ . E. long.  $220^{\circ} 50'$ .

**RIOXA**, a province of Spain, situated in Old Castile, on the borders of Biscay, on the banks of the Ebro.

**RIPA CANDITA**, a town of Naples, in the province of Basilicata; six miles S.W. of Venosa.

**RIPA Limosara**, a town of Naples, in the county of Molise; nine miles E. of Molise.

**RIPA Tranfona**, a town of the marquisate of Ancona, the see of a bishop, suffragan of Fermo; 12 miles N.E. of Ascoli. N. lat.  $42^{\circ} 58'$ . E. long.  $13^{\circ} 49'$ .

**RIPAILLE**, a town of France, in the department of the Lemane lake, on the S. side of the lake of Geneva, with a convent; one mile N. of Thenon.

**RIPEN**, a sea-port of Denmark, in North Jutland, on the Gram; the see of a bishop, and capital of the diocese. This town was probably built about the time of the introduction of Christianity into this kingdom, and, next to Wiborg, is deemed the most ancient town in North Jutland. It was formerly one of the most celebrated and flourishing cities in the North; as it had four parish churches and five chapels, besides the cathedral, four convents with their churches, a strong castle, and between 600 and 700 free burghers. A considerable number of ships traded to Norway, France, England, Holland, &c. from this port; and the city had the privilege of coining money. But its grandeur and opulence were almost annihilated by a dreadful fire in 1580, and other conflagrations, by inundations, and by the ravages of war. The merchants' old Exchange is converted into a town-house. Some little trade is still carried on at this place, in grain, horned cattle, horses, &c.; but the shallowness of the river admits only small vessels to come up to the city, and these only at high water; 77 miles S. of Wiborg. N. lat.  $55^{\circ} 21'$ . E. long.  $8^{\circ} 46'$ .

**RIPENERS**, in *Medicine*, a sort of topical remedies, called also *drawers*, *digestives*, *naturantia*, *suppuratives*, &c. See **MATURATION**.

**RIPENING of Fruit**, in *Gardening*, may be forwarded several ways. See **CAPRIFICATION**, **HOT-Beds**, and **FORCING**.

**RIPERA**, in *Geography*, a town of Hindoostan, in Berar; 25 miles N.E. of Notchegong.

**RIPERTNAU**, a town of Westphalia, in the county of Lippe; three miles E.N.E. of Lemgow.

**RIPRIENO**, Ital. in *Musie*, implies full, in opposition to *solo*. In Corelli's concertos, the solo parts are said to

be *del concertino*, the little concert; and the *tutti* parts, or *ripieno*, *del concerto grosso*, of the great concert. The first eight of Corelli's concertos were composed for the church, *a due cori*, for two bands or choirs, which are often in dialogue. By *ripieno* is always meant a subordinate part, to which few difficulties are entrusted; being what the French call *complissage*, or parts to fill up and complete the harmony.

**RIPRIERS**, **RIPRIARI**, in our *Old Writers*, those that bring fish from the sea-coast to the inner parts of the land.

They were thus called a *fiscella*, *qua in devehendis piscibus utuntur*, *Anglice*, a rip.

**RIPLEY**, in *Geography*, a market-town and parish, partly in the lower, and partly in the upper division of the wapentake of Claro, West-riding of Yorkshire, England, is five miles N.W. from Knaresborough, and 214 miles N.N.W. from London. The town had formerly a castle attached to it, some part of which is yet standing. The market here is held on Monday, weekly; and there are annual fairs on Easter Monday, and the 25th, 26th, and 27th days of August, for horses, horned cattle, and sheep. A free-school at this place, as appears from an inscription over its entrance, was built and endowed in the year 1702, by Mary, and Catharine Ingilby, daughters of sir William Ingilby, then lord of the manor. The church is ancient, and contains many monumental erections in memory of that family. In the church-yard stands the pedestal of an ancient cross, which contains eight niches curiously ornamented, but the effigies are gone, as likewise the shaft of the cross. This parish, according to the parliamentary returns of 1811, contains 222 houses, and 1053 inhabitants.

Ripley-castle, the seat of sir John Ingilby, baronet, adjoins the town. The chief part of it was built by sir William Ingilby, in the reign of Philip and Mary, but the great tower is far more ancient, having belonged to a former structure. It has been much enlarged of late years; and is now a stately and commodious family mansion. Some of the apartments are finished with great elegance; and the staircase displays a large Venetian window of stained glass, on which is represented a series of shields, shewing the quarterings and inter-marriages of the Ingilby family, since their settlement at Ripley, towards the close of the fourteenth century.

Eastward from Ripley is Copgrove, an elegant mansion belonging to H. Duncombe, esq. which contains an excellent collection of paintings, busts, and prints from the most celebrated masters. The pleasure-grounds are extensive, and are ornamented with a fine lake. Near this seat is that of Alerton-Mauleverer, the property of lord Stourton. The house is a modern edifice, built by his royal highness the duke of York. It is surrounded by a park, containing 400 acres of land, chequered by hills and dales. At this place was formerly a priory of Benedictines, subject to the abbey of Marmontier in France. It was founded by Richard Mauleverer in the reign of Henry II., and was dissolved by Henry VI. who settled its revenues on King's college, Cambridge. Beauties of England Wales, vol. xvi. by John Bigland.

**RIPOGONUM**, in *Botany*, so called by Fœrster, from  $\rho\acute{\iota}\nu\acute{\iota}$ ,  $\rho\acute{\iota}\nu\acute{\iota}\sigma$ , a slender twig, and  $\gamma\omicron\nu\nu$ , a joint, because of its slender, jointed, twining habit, was referred by the son of the author, as well as by the younger Linnæus, to **SMILAX**; (see that article.) Mr. Brown, nevertheless, retains *Ripogonum*, in Prodr. Nov. Holl. v. 1. 293, because of its hermaphrodite flowers, the two bractæas at the base of each, and the racemose inflorescence. Two species are mentioned,

*R. album* and *parviflorum*, the latter of which is Forster's plant, *Smilax Ripogonum*, Forst. Prodr. 70.

RIPOLL, in *Geography*, a town of Spain, in Catalonia; 14 miles N. of Vique.

RIPON, or RIPON, a market and borough town in the lower division of the wapentake of Claro, liberty of Ripon, West-riding of Yorkshire, England, is situated at the distance of 11 miles N. from Harrowgate, and 222 miles N.N.W. from London. It occupies the declivity of a gentle eminence, between the rivers Ure and Skell, and not far from their confluence. Over these rivers are six bridges, within a mile of the town. One of these is a very handsome structure of stone, and has seventeen arches. The town is large, and the buildings are in general good; particularly in the principal street. According to the parliamentary returns of 1811, the parish contains 452 houses, and 2346 inhabitants, but this does not appear to include the borough, which is omitted in the reports.

The origin of Ripon is to be referred to a very remote era. By Salmon, it is supposed to have been the Roman *Isurium*, but this opinion is erroneous. The probability on the subject is, that it owes its foundation to the monastery which was established here in the year 661, by Eata, abbot of Melros, in Scotland. About that period we find it first mentioned in historical record, when it is said to have consisted only of thirty houses. This town was destroyed by the Danes, and remained a heap of ruins for several years. At length, however, it was rebuilt; and in the year 886, king Alfred is said to have incorporated it as a royal borough, to be governed by a *vigillarius*, or wakerman, twelve elders, and twenty-four assistants. Ripon was destroyed a second time by king Edred in revenge of a revolt of the Northumbrian Danes. This event occurred in the year 950; after which Ripon was again rebuilt and began to flourish, but did not long remain in a state of tranquillity. In the year 1069 it once more shared in the fatal consequences of a revolt of the Northumbrians against the Norman Conqueror; and sixteen years later, at the time of the general survey, the town, and the country around it, still remained waste and uncultivated. Peace having been restored, however, Ripon again revived from its embers, and continued in a prosperous condition, till the wars between England and Scotland, in the reign of Edward II. subjected it to new misfortunes. In the year 1323, Robert I. king of Scotland, having driven Edward and his army out of his kingdom, invaded England, laying waste the country with fire and sword to the very walls of York. Ripon suffered in the general devastation, the houses having been destroyed by fire, and most of its inhabitants put to the sword. No sooner, however, had the victorious career of Edward III. freed the country from the invaders, than it was restored to a prosperous condition, principally through the exertions of the archbishop of York, and the liberality of the neighbouring gentry, many of whom fixed their residence here. Since that time Ripon has been occasionally honoured by royal visits. Henry IV. retired hither, with his whole court, in 1405, when the plague raged in London. In the year 1604, a similar cause occasioned the removal of the lord president's court from York to this town.

Ripon first sent members to parliament in the 23d year of Edward I., but this privilege was soon after discontinued, and was not revived till the reign of Edward VI. The patronage of the borough is vested in Miss Laurence, of Studley-Royal, who possesses all the burgage tenements to which the right of election is attached. The number of voters is 146, and the mayor is the returning officer. The corporation, by virtue of a charter granted by king James I., and since confirmed, and, in some degree, extended, by

succeeding monarchs, consists of a mayor, recorder, 12 aldermen, 24 assistants, a town-clerk, and other inferior officers. Ripon was formerly celebrated for its manufacture of spurs, which were, indeed, so highly esteemed, that it became a proverbial expression to say "As true steel as Ripon rowels," when speaking of a man of fidelity, honesty, or intrepidity. The manufacture of woollens likewise flourished here, in former times, but this branch of business is now completely decayed. The archbishop of York has his court and prison here for the liberty of Ripon. On the nomination of the archbishop, and by his majesty's commission, justices are appointed, who, in conjunction with the mayor and recorder, hold sessions for the town and liberty. The dean and chapter of Ripon minister have likewise a prison here, and hold a court for the decision of causes arising within their manor. The market day here is Thursday; and there are fairs on Thursday after 13th January, 12th and 13th May, first Thursday in June, first Thursday after 22d August, and 22d November. The market-place is a handsome and spacious square, surrounded by well-built houses, and having in the centre an obelisk 90 feet high, erected, in 1781, by William Aislaby, esq. of Studley, who represented this borough in parliament during the long period of sixty years. Here also stands the town-hall, built in 1801, from designs by Mr. Wyatt, and at the expence of the late Mrs. Allanson of Studley. A theatre was erected here in 1792, by the late George Hassell, esq. The free-grammar school was founded by king Edward VI., and was finished, and amply endowed, by his successor, queen Mary, in 1553. The other public establishments belonging to the town are, a dispensary, Sunday schools, a school of industry, and four hospitals, *viz.* that of St. Mary Magdalen, for six poor women; of St. John, a small building, appropriated to two poor women; St. Anne, which supports eight women; and Jepson's hospital, in which twelve poor boys are maintained, clothed, and educated. This hospital was founded, in 1672, by Zacharias Jepson, a citizen of York.

The monastery, previously mentioned as the probable nucleus which gave rise to the town, appears to have been of considerable celebrity. After the destruction of the original buildings in the reign of Alfred, king of Northumbria, it was re-erected in a style of more magnificence than was usual in that age, by the famous Wilfrid, archbishop of York. William of Malmesbury mentions the new structure as remarkable "for its curious arches, its fine pavements, and winding entries." The same author says it was much resorted to by the northern nobility, and was endowed with very extensive possessions. The memory of St. Wilfrid is still honoured by an annual feast and procession at this town. His monastery received extraordinary marks of royal munificence. The great king Athelstan granted to it many immunities, and particularly the privilege of sanctuary. From that period history records few particulars respecting this establishment, except its destruction by the Scotch in the reign of Edward II., when it ceased to be a monastic foundation. The church, however, was rebuilt and made collegiate by archbishop Melton, from whose time, till the reign of Henry VIII., it had seven prebends, with distinct revenues, attached to it; besides nine chantries within the church, which were dissolved by Edward VI. King James I. renewed the collegiate privileges of this church, by the establishment therein of a dean and six prebendaries, to whom he granted "divers lands, prebends, chantries, and rectories, belonging to the said church before the dissolution." In 1607 the same monarch added a subdean, and thus completed the college as it still exists.

Ripon church is dedicated to St. Peter and St. Wilfrid, and has, attached to it, a peculiar jurisdiction, under the archbishop of York. The king is patron of the deanery; and the subdean is nominated by the dean from among the prebendaries. When a vacancy occurs in the number of the latter, the dean and chapter present three persons to the archbishop, who collates one of them. As a building, this church has considerable claims to the notice of the antiquary, though its appearance has been much injured by additions and alterations executed at different periods and in different styles of architecture. Its general form is that of a cross, having two uniform square towers, each 110 feet high, at the west end, and a third, called St. Wilfrid's great tower, in the centre of the transept. From the last, there formerly rose a very noble spire, which was blown down Dec. 8th, 1660.

The sepulchral monuments in the church are too numerous to be mentioned in detail. There are many in commemoration of different branches of the principal families in the neighbourhood, especially the Blackets; the Kitchenmans; the Ridfdales; the Wanleys; the Oxleys; the Nortons, of Sawley; the Weddels, of Newby; the Mallories and Ailsabys, of Studley; and the Markenfields, of Markenfield. Among these may be noticed a beautiful monument to the memory of W. Weddel, esq. the design of which was taken from that curious relic of antiquity, the Lantern of Demosthenes, at Athens. An altar-tomb, of grey marble, situated in the south aisle of the nave, is said to commemorate an Irish prince, who died at Ripon on his return from the Holy Land. On the entablature are represented the sculptured figures of a man and a lion in a grove of trees.

The environs of Ripon are rich, fertile, well wooded, in a high state of cultivation, and interspersed with villages, and seats of the nobility and gentry. Among the latter the principal are, Studley-Royal, and Newby-Hall. The first is the property of Miss Laurence, and is situated at the distance of nearly three miles S.W. from Ripon. The house is commodious and elegant, and contains many excellent pictures, and portraits by the best masters. But the chief objects of attention here, are the park and pleasure-grounds, which are generally ranked among the finest in England. The park, which is situated nearest the house, is diversified with gentle swells and declivities, and is adorned with ranges of lofty trees. The entrance to the pleasure-grounds displays a mass of the most luxuriant foliage, and the widely extended plantations which compose them, are judiciously varied, and finely adapted to the different situations. On one hand the hills gradually ascend with tufts of shade, interspersed over the verdure; on the other side they precipitately rise with lofty woods covering their brows, below which the rivulet, in one place, glides with a silent stream, and in another falls in cascades. Near the entrance is a building, called the Cold Bath, which is constantly supplied by a spring of pure water. Adjoining is the figure of a dying gladiator, and further on is a fine rustic bridge with the river rushing through it, and the back-ground so darkened by trees as to excite the idea of a cascade foaming through a cavern. Near this is a statue of Hercules destroying Antæus. The view now opens with a beautiful assemblage of new objects, most charmingly diversified. From a little grotto not far distant a fine expansive lake is seen winding round the base of an eminence, called Tent Hill, encircled by a magnificent amphitheatre of hanging wood. The lawn is laid out with exquisite taste, and here the water divides itself into various and beautiful forms, embellished at different points by statues of Neptune, Bacchus, Galen, a dying gladiator, and Roman wrestlers. On rising grounds are situated a

temple of Piety, a Chinese temple, a temple of Fame, a banquetting-house, and various other ornamental buildings.

Near Studley-Royal are the venerable ruins of the once celebrated Abbey of Fountains, which was founded in the year 1132, for the monks of the Cistercian order, but soon afterwards suffered total demolition by fire. It was rebuilt, however, in 1204, in the early pointed style of architecture, which then began to prevail; this house continued to flourish till the general dissolution in the reign of Henry VIII., when its annual revenues, according to Speed, were valued at 1073*l.* or. 7½*d.* This abbey, with all its offices and appendages, covered about twelve acres of ground. The church, the walls of which are still almost entire, appears to have been a very large and magnificent structure. The nave, in particular, is a most majestic specimen of building, uniting simplicity with lightness and elegance. The Ancient and Modern History of the Loyal Town of Rippon, by Thomas Gent of York, 8vo. 1733. History of Rippon, 12mo. 1801. Beauties of England and Wales, vol. xvi. by John Bigland. Drake's Eboracum, folio.

RIPOSTE, in the *Manege*, is the vindictive motion of a horse that answers the spur with the kick of his foot.

RIPOUR, in *Geography*, a town of Hindoostan, in the circar of Gohud; 40 miles S.S.W. of Gwalior.

RIPPACANOT CREEK, a river of America, near the western branch of the river Wabash.

RIPPERDA, JOHN WILLIAM, in *Biography*, baron of, was born in 1680, of a noble family, in the province of Groningen. He was educated in the principles of the Catholic religion, but upon marrying a Protestant heiress, he conformed to the Protestant faith. He appears to have entered the army while he was young, and for some time he was in the service of the States-General as colonel of the infantry, which post he occupied in the year 1715, when he was sent from the States to the court of Spain, to negotiate a commercial treaty. Having ingratiated himself with the king, Philip V., he returned to the Catholic religion, and took up his abode at Madrid. His first wife being dead, he married, in 1721, a Castilian lady of high birth, and rapidly rose in the confidence of the king. In 1725 he was sent to Vienna to negotiate an accommodation with the imperial court. In the same year he signed a treaty at Luxembourg with the emperor's plenipotentiaries; and on his return to Madrid he was created a grandee of the third class, and duke of Ripperda. He also obtained the office of secretary of state for foreign affairs; and the management of the war, marine, and financial departments, was entrusted to him, so that he had all the power, without the name, of prime minister. In a short time he was not only dismissed from his employments, but confined in the castle of Segovia, where he remained two years, when, having found means to make his escape into Portugal, he passed from thence into England, where he remained till 1730, when he went to the Hague, and resumed the Protestant religion. After this he formed a connection with an envoy from Morocco, and in 1731 embarked for that country. He was favourably received by the sovereign, Muley Abdallah, to whom he proposed a scheme of uniting the Barbary states against Spain, and of invading that country. He engaged the Moors to undertake the siege of Ceuta, and having declared himself a convert to the Mahometan religion, and assumed the name of Osman, he was nominated to the chief command of the army employed for that purpose. By his military talents he inspired the Moors with confidence in their enterprise, when the arrival of a Spanish army in Africa, which laid siege to Oran, disconcerted his plans. Nevertheless, he persisted in the siege of Ceuta,

Ceuta, and defeated the garrison which had sallied out against him. But a nocturnal surprise of the Moors in the trenches broke up the siege, and Ripperda, who fled in his shirt to Tetuan, was received so coldly at the court of Morocco, that he meditated an escape to some other country. He was stopped by the emperor, and fully expected to pay the forfeit of his life, on account of his success; but he pleaded his cause with so much effect, that he was, after a short imprisonment, set at liberty. He now formed a new project, which was a consolidation of different religions, especially the Mahometan and Jewish, which he endeavoured to render compatible by admitting the prophetic character of Mahomet, and inculcating the expectations of a future Messiah. He made some converts to his opinions; but at length became suspected of dishonest motives, and was obliged to retire. His projecting spirit continued to the last, and he advanced considerable sums to Theodore for his attempts on the crown of Corsica. He died at Tetuan, in 1737. *Universal History. Gen. Biog.*

RIPPERS, in the *Wire-works*, are the people who attend in the mills, take the prepared small rods of iron, and work at the barrels where they are drawn into wire.

RIPPIN, or RUPULAM, in *Geography*, a town of Hungary; eight miles N.N.E. of Leopoldstadt.

RIPPINICA, a town of the duchy of Warsaw; 25 miles N. of Wladislaw.

RIPPLE, in *Agriculture*, a slight scratch or tear, sometimes applied to very slight ploughings, hence called ripplings.

RIPPLE, in *Rural Economy*, an implement of the comb kind, constructed with several upright triangular prongs, set near together in a strong piece of wood, for the purpose of rippling flax and hemp.

RIPPLING, in *Sea Language*, a broken and interrupted noise, produced by a current on or near the sea-coast.

RIPPLING of Flax, in *Rural Economy*, the operation of taking off the seed from the flax by drawing it through a ripple or large comb. See FLAX, and RIPPLE.

RIPPON, in *Geography*. See RAPON.

RIPRAPPS, a narrow shoal in the English channel, between Folkestone and Boulogne, S.W. and N.E. about 10 miles; with a strong bottom, and at a low spring-tide not covered above 14 feet with the sea.

RIPRESA, Ital. the same as *reprise* in French, and *repeat* in English; which see.

RIPSA, in *Geography*, a town of Sweden, in Sudermanland; 13 miles N. of Nykoping.

RIPTON, a township of America, in the county of Addison and state of Vermont; containing 15 inhabitants. RIQUEVILLI.E. See RICHENVEIR.

RIQUEURIA, in *Botany*, a name in the Flora Peruviana, destined to commemorate Lewis Riqueur, apothecary to king Philip V. of Spain. *De Theis.*

RIS, in *Geography*, a town of France, in the department of the Puy-de-Dôme, near the Allier; nine miles N. of Thiers.

RISACO, a town of Dalmatia, in the bay of Cataro; 20 miles N.N.W. of Ragusa.—Also, a river of Istria, which runs into the gulf of Trieste, about three miles from Capo d'Istria.

RISARD, FRANCIS, in *Biography*, a French mathematical writer in the eighteenth century, published several esteemed elementary works for the instruction of the young in the sciences. He was a native of Neufchateau, in Lorraine, and was made professor of philosophy in the college of Beauvais; he died at Paris in the year 1778. His pro-

ductions consist of "Elements of the Mathematics," in 4to., of which the author published an abridgment, in 8vo.; "A Treatise on the Sphere," in 8vo.; "A Treatise on Gnomonics," in 8vo.; "Tables of Sines," in 8vo.; "Rectilinear Trigonometry," 8vo.; "Elements of Geometry," in 4to.; and "Institutiones Philosophicæ," in 2 vols.

RISBOROUGH, or PRINCE'S RISBOROUGH, in *Geography*, a market-town and parish in the second division of the three hundreds of Aylebury, county of Buckingham, England, is situated at the distance of 5 miles S.W. from Wendover, and 37 N.W. from London. The right of holding a market was granted to the inhabitants by king Henry III., who, at the same time, bestowed upon the townsmen many privileges. The market day is Saturday, weekly; besides which there is an annual fair on the 6th of May. The manor here was anciently vested in the families of Gifford and Humet; but having subsequently become vested in the crown, it was granted to Richard, earl of Cornwall, and king of the Romans, who died in 1272. It was afterwards the property of Edward the black prince, who is said "to have had a palace here, supposed to have stood within the scite of a spacious moat, now dry, which is in a field adjoining the church-yard." In the reign of Henry V. this manor was assigned to his queen, Catharine, in dower. Charles I. sold it to certain citizens of London, who, in 1637, conveyed it to the family of the Chibnalls; one of whom gave a considerable sum of money to the parish to supply clothing annually to 24 poor women. Since the Chibnalls, it has been occupied successively by the families of Abraham, Adeane, Pelham, Panton, and Grub, the present possessors. According to the parliamentary returns of 1811, this parish contains 324 houses, and 1644 inhabitants.

Adjoining to Prince's Risborough is the village of Monk's Risborough, at which place, it is said, there was formerly a cell of Benedictine monks, subject to the monastery of Christ-church, in Hampshire. The church here is a handsome building, in the later pointed style of architecture, and contains many monuments. Lysons's *Magna Britannia*, vol. i. Bucks, 4to.

RISBY, a town of Sweden, in the province of Finland, near the gulf of Bothnia; 32 miles N. of Bjorneborg.

RISCHEBACH, a river of Saxony, which runs into the Elbe, near Wittenberg.

RISCHIN, a town of Bohemia, in the circle of Rakonitz; 30 miles S.E. of Rakonitz.

RISCLE, a town of France, in the department of the Gers; six miles S. of Nogaro.

RISCUS, among the Romans, sometimes signifies a chest or trunk covered with skins; sometimes it is used for a hamper, made of twigs or rushes to hold lint; and sometimes for a hollow place in the wall of a house, used likewise for holding lint, or the like.

RISEBERGA, in *Geography*, a town of Sweden, in the province of Skone; 28 miles N. of Lund.

RISENBURG, a town of Prussia, in the province of Oberland; 12 miles E. of Marienwerder.

RISENKIRCH, a town of Prussia, in the province of Oberland; 14 miles E. of Marienwerder.

RISENTI'FO, in the *Italian Music*, a brisk, lively, or expressive manner of playing.

RISHI, in *Hindoo Mythology*, is a general name for ancient sages or saints. Considerable difficulty occurs in determining, with any exactitude, who they were, whether they had any historical existence, or are merely the crea-

tures of the imagination. Seven of them are most frequently spoken of; by some said to be the first rational beings created by Brahma. Each has a wife, and a numerous offspring. The names of these seven differ in different authorities; but the following list is that usually received. 1. KASYAPA; 2. *Atri*; 3. VASISHTA; 4. VISWAMITRA; 5. Gautama or GODAMA; 6. JAMADAGNI; 7. *Bharadwaja*. (The names distinguished by capitals have furnished articles in this work.) The wives of these patriarchs have been transferred to the heavens, and are the stars called by western astronomers the Pleiades; by the Hindoos, KRITIKA, under which word will be found some information respecting them, shewing that the astronomical fabulists of both races have common legends. The Rishis are said to be the bright stars in the great bear. How they became so distant from their sparkling spouses is explained in the article just referred to. In several languages of India, a bear is called Rishi; and there may be some allusion both to the constellation and the sages in question. Sometimes the seven Rishis, and the seven Menus, are confounded. (See MENU.) Another race of patriarchal sages is also sometimes confounded with both. These are the Munis. See MUNI; in which article the reader is requested to correct a typographical error, in the second column, third line from bottom, for *many-mothered*, for, read *many-mothered son*. Jamadagni, for instance, is usually called a Rishi; yet in our article given under the name of his wife, RUNEKA, he is, on Puranic authority, called "a great Muni." The Rishis, as the immediate production of Brahma, are sometimes called Brahmadikas, of whom likewise there are seven; but they are not usually supposed to be the same with the Rishis; some lists have no names in common with those of the Rishis; others have several. As the production of Brahma, there is another set of seven beings of different names from any of the above-named lists, but employed in early days in peopling the world; these are called Sanakadikas, of whom something is said under the name of their principal, SANAKA. The Hindoo books differ very much in their accounts of these varieties of persons interposed between the Supreme Being and the created world; and it is not easy, if at all practicable, to reconcile their disagreements; nor perhaps worth the pains were it otherwise.

We shall not attempt to notice the disagreements, that could be picked out from high Hindoo authorities, respecting the equivocal personages named in this article. It may be briefly observed, that although the seven Rishis are very commonly adverted to, the appellation is by no means confined to that number. In the Siva Purana, Brahma is said to have produced Brighu and the seven Rishis, and after that Nareda, from his thigh, Kardama the Rishi from his shadow, and from the fore-finger of his right-hand, Daksha. These persons are sometimes called Rishis, Brahmadikas, Maharshis, Devarshis, &c. A sage of the name of Dadichi occurs in the Skanda Purana, as having swallowed the sacred books, for their security, at a period of great wickedness and tumult. He is called a Rishi; as is another named Uddalaka, who was half betrothed to Lakshmi, the goddess of wealth; but espoused her sister Jyestha, goddess of poverty. These allegories may be explained. (See UDDALAKA, and KARDAMA.) Other Puranas seem to identify in some parts the Rishis and Munis, calling both "the virtuous sages, who delight in protecting the people." In other parts distinctions are made. In the beginning of this article we have stated the term Rishi to be, as it were, generic; meaning sages, faints, patriarchs. This seems authorized by the Ramayana, where this note occurs.

"There are four kinds of Rishis, or sages; the Rajarshi, or royal sage; the Maharshi, or great sage; the Brahmarsi, or sacred sage; and the Devarshi, or divine sage. Of these the first is esteemed the lowest, and the last the highest." These appear to be the specific varieties. In addition to the articles already referred to, some farther points connected with the subjects of this will be found noticed under the following: MAHARSHIS, MATSYAVATARA, PIKESWARI, PITRIS, PULAHA, PULASTYA, RAJARSHI, RAVENA, RUNEKA.

RISIBILITY, the faculty of *laughter*; which see.

Risibility is commonly supposed an attribute peculiar to man; as being the only creature capable of judging what is ridiculous.

Some philosophers go so far as to assert, that the degree of judgment is always seen in that of laughter; fools always either have too little or too much of it.

Authors do not agree as to the peculiar mechanism in man, by which laughter is raised. It is usually attributed to the communication between the plexus nervosus, and the diaphragmatic nerves. See LUNGS.

RISIGALLUM, in the *Materia Medica*. See REALGAR.

RISING, in *Astronomy*, the appearance of the sun, a star, or other luminary, above the horizon, which before was hid beneath it.

By reason of the refraction of the atmosphere, the heavenly bodies always rise before their time; *i. e.* they are seen above the horizon, while they really are below it. See REFRACTION of the Atmosphere.

There are three poetical kinds of rising of the stars. The *Acronychal*, *Cosmical*, and *Helical*; which see respectively.

To find the rising, &c. of the sun and stars by the globe, see GLOBE.

RISING, in *Rural Economy*, a term sometimes applied to yeast, or barm used for the purpose of fermenting different matters.

RISING, in *Ship Building*, a term derived from the figure of a ship's bottom in general, which gradually narrows or becomes sharper towards the stem and stern-post. On this account it is that the floors, towards the extremities of the ship, are raised or lifted above the keel; otherwise the shape would be so very acute, as not to be obtained from timber with sufficient strength in the middle or cutting-down. The floor-timbers forward and abaft are therefore gradually lifted or raised upon a solid body of wood, called the *dead or rising-wood*, which masts of course have more or less rising as the body of the ship assume more or less fullness or capacity.

RISING of Boats, is a narrow strake of board fastened withinside to support the thwarts.

RISING-Floors are the foremost and aftermost floors, which, on account of the rising of the body, are the most difficult to be obtained, as they increase in the acuteness of shape; and to preserve strength in the throat, the cutting-down must be deeper.

RISING-Line, an elliptical line drawn in the plan of elevation, by which line, with its corresponding half-breadth or narrowing line, the figure of the bottom near the floor-heads is determined.

RISING-Square, a square used in whole moulding, upon which is marked the height of the rising-line above the upper edge of the keel.

RISING-Straight, is a curve line used in whole moulding drawn in the sheer plan, at the intersection of the straight part

part of the bend mould, when continued to the middle line at each timber.

**RISING-Wood**, that part of the basis of a ship's body, forward and abaft, which is formed by solid pieces of timber scarfed together lengthwise on the keel. The rising-wood must be sufficiently high to seat the floors; and afore and abaft the floors, it is continued up to the cutting-down or upper side of the floors, for the purpose of securing the heels of the cant-timbers, and there left sufficiently broad to admit of a stepping or rabbit for the heels of those timbers, that they may not be continued downwards to sharp edges.

**RISK, or RISQUE**, the hazard or chance of a loss, damage, &c.

There is a great risk run in letting goods go upon credit to great lords, wives not authorized by their husbands, and young people not yet arrived at the age of majority.

Skinner derives the word from the Spanish *risco*, *steep*; Covarruvias, from *risco*. In the barbarous Greek, they say,  $\mu\acute{\iota}\kappa\alpha\sigma\epsilon\iota\varsigma$ , for *perilitor*, *I hazard*; and  $\mu\acute{\iota}\lambda\lambda\omicron\sigma$ , for *lot or chance*; which words, as well as *risque*, Skinner thinks, may be deduced from  $\mu\acute{\iota}\tau\tau\alpha$ , for *αναμ\acute{\iota}\tau\tau\omega\ \tau\omicron\upsilon\ \kappa\upsilon\delta\omicron\varsigma*, *I cast the die*.

To prevent any risk in invoices of merchandizes by sea, it is usual to insure them.

Accordingly the risk is a subject of primary consideration in cases of marine insurance. All the risks or perils, that are incident to sea-voyages, may be provided against by insurances, with certain exceptions founded on public policy and the interests of humanity. Thus, the insurer can, in no case, upon principles of natural justice, make himself answerable for any loss or damage, proceeding directly from the fault of the insured. No insurance can be made, even against the perils of the sea, upon illegal commerce. In most foreign countries, insurances on the lives of men are prohibited. In France they have been always deemed illegal, and are expressly forbidden by the ordinance of Lewis XIV.; nevertheless, French writers have held that this does not apply to Negro slaves. According to Valin, who has, by curious reasoning, attempted to vindicate this doctrine, the disposition to suicide is natural in Negro slaves, and imputable, as he expresses himself, to the "inherent vice of the article;" and, therefore, their death, proceeding from this cause, must be deemed natural death. But the killing of them, or the throwing of them overboard in a revolt, is a loss incident to this trade, and a peril within the policy. It is to be lamented, that, whilst the slave trade was countenanced and carried on in this country, the objects of this cruel traffic have been too much considered as mere merchandize; and the insured upon this trade formerly recovered, under the common policy, for any loss sustained in the voyage by the mortality of the slaves, whether they were thrown overboard, in cases of supposed necessity, or died a natural death, or perished by the perils of the sea. The legislature, however, while this infamous and savage traffic subsisted, interposed, and by an annual act, passed with a view to *interest* the persons concerned in this trade in the preservation of the lives and health of the slaves, declared, that though the policy remained in the same form as before, it cannot protect the insured against losses occasioned by natural death, ill treatment, throwing overboard, or by restraints of princes proceeding from attempts to get slaves by force. (See stat. 30 Geo. III. c. 33. § 8. 34 Geo. III. c. 80. § 10. and 39 Geo. III. c. 80. § 24.) But we trust the provisions of these and similar statutes are become wholly unnecessary in this country, and that the trade, of

which we shall give some account in its proper place, is abolished never to revive.

The words of an English policy, which specify the various risks against which insurances are usually made, are these: "Touching the adventures and perils which we, the assurers, are contented to bear, and do take upon us in this voyage, they are of the seas, men of war, fire, enemies, pirates, rovers, thieves, jettisons, letters of mart and countermart, surprizals, takings at sea, arrefts, restraints, and detainerments, of all kings, princes, and people, of what nation, condition, or quality soever; barratry of the master and mariners; and of all other perils, losses, and misfortunes, that have or shall come to the hurt, detriment, or damage of the said goods and merchandizes, and ship, &c. or any part thereof, without prejudice to this insurance." The latter clause seems to be sufficiently comprehensive to embrace every species of risk to which ships and goods are exposed from the perils of sea-voyages. However, by the agreement of the parties, the general words of the policy may be altered or qualified; and any of the risks may be wholly or in part excluded, and the insurance may be made only against some particular risks, or up to, or beyond certain degrees, or upon particular articles. In England, it is now constantly stipulated in all policies, that upon certain enumerated articles of a quality peculiarly perishable, the insurer shall not be answerable for any partial loss whatever; that upon certain others, liable to partial injuries, but less difficult to be preserved at sea, he shall only be liable for partial losses above *five per cent.*; and that, as to all other goods, and also the ship and freight, he shall only be liable for partial losses above *three per cent.* This stipulation is made by a memorandum, in the form of a warranty, inserted at the bottom of all English policies. It was first introduced here about the year 1749; before which time the insurer was liable for every injury, however small, that happened to the thing insured. This clause prevented the necessity of adapting the premium to the nature of the commodity. Nevertheless our policies indemnify the insured against every loss, let it be ever so inconsiderable, arising from any cause affecting the general safety of the ship and cargo. Losses of this sort, being of the nature of "general average," are so called in the memorandum; and there is, therefore, annexed to each of the provisions above-mentioned, an exception of general average. In the policies of private insurers, the case of the "stranding of the ship" is likewise excepted. In the common policies, used in London by private underwriters, the memorandum runs thus: "Corn, (comprehending every sort of grain, and also pease and beans,) fish, salt, (excluding salt-petre,) fruit, flour, and seed, are warranted free from average, unless general, or the ship be stranded: sugar, tobacco, hemp, flax, hides, and skins, are warranted free from average, under *five per cent.*; and all other goods, also the ship and freight, are warranted free from average, under *three per cent.*, unless general, or the ship be stranded."

This form of the memorandum was generally used, not only by private underwriters, but also by the two insurance companies, from its first introduction in 1749, till the year 1754; when, in consequence of a particular case that occurred, the London Insurance Company left out of the memorandum in their policies the words, "or the ship be stranded;" and the same alteration was soon after adopted by the Royal Exchange Assurance Company. Private underwriters have, however, continued the memorandum in the old form. Many questions have arisen as to the true meaning of the words, "free from average, unless general,

or the ship be stranded." The word "unless" has been held to make an *exception*, and not a *condition*; and cases have occurred in which judges of the highest eminence have put a different construction upon the fore-mentioned clause. It is now settled, that if the ship be stranded, the insurer is liable for any partial loss in any of the articles in the memorandum, though such loss did not arise from the stranding, but from some other cause. Notwithstanding the number of cases, which have been decided upon the construction of the memorandum, it still remains a question, whether the partial losses, from which the insurer is exempted by it, comprehend the *total loss of an entire individual*, as well as a partial injury to the *whole* of the species of goods exempted by the memorandum from small average losses; as, *e. gr.* if out of 101 hogheads of sugar of equal value, five are so completely spoiled in the voyage, as to be worth nothing, and therefore *totally lost*. If this loss be calculated upon the whole 101 hogheads, it will not amount to *five per cent.* In such a case, it has been thought, that the insurer would be protected by the memorandum, and not liable for the loss. But the question has not been decided.

There are certain injuries or losses, to which goods on ship-board are liable, that do not arise from the perils of the sea; and for these the owners are liable. These may be owing to some fault or defect of the ship: in this case the insurer is not liable, because, in every contract of insurance, there is an implied warranty, that the ship is sea-worthy; and if it appear otherwise, the contract is void. In many cases, the master also, as well as the owners, is answerable. He is bound to deliver goods in the same state in which he received them; and of course he, as well as the owners, is liable for all loss or damage not proceeding from some inevitable misfortune. They are answerable for loss or damage occasioned by bad stowage, wet, theft, embezzlement, rats, &c. This is the rule of the marine law, and agrees with the common law. At common law, the owners and master were liable to the full value of the goods lost; but now by 7 Geo. II. c. 15. they shall only be liable to the value of the ship and freight for any act done by the master or mariners. The master's liability, and that of the mariners, remains the same. But as this provision only extended to the case of embezzlement, &c. by the master or mariners, it did not afford a sufficient protection to ship-owners. Therefore the 26 Geo. III. c. 86. limits the liability of the owners to the value of the ship and freight, though the master or mariners should not be privy to such robbery, &c.; and they are exempt from all liability for any loss by fire. But though the owners are responsible to the amount of the value of the ship and freight, for losses occasioned by external thieves; yet, under the policy, the insurers are also liable; and, therefore, in such cases, the proprietor of the goods, or the insurers in his name, may recover against the owners.

In order to charge the insurer, the loss must happen during the continuance of the risk. This brings under consideration a subject of importance. Every voyage insured must have a fixed commencement and termination. It is proper, therefore, to inquire what is the duration of the risk, with reference to insurances upon *goods*, upon the *ship*, and upon *freight*. In France, and most other countries, it is provided, that if the time of the risk be not regulated by the contract, it shall commence, as to *goods*, from the time they are put on board the ship, or put into barges, to be conveyed on board, that is, from the moment of their leaving the shore; and it continues till they are safely landed at the place of their destination. It is alleged, that the perils of

the sea commence from the moment in which the goods are on the water. In our policies, the words usually employed to express the commencement and end of the risk on *goods* are these: "Beginning the adventure upon the said goods and merchandise *from the loading thereof aboard the said ship*, and so shall continue and endure until the said ship, with the said goods, shall be arrived at — (her port of delivery), and until the same be discharged and safely landed." With us, therefore, the risk does not commence until the goods are actually on board the ship; and, therefore, the insurer is not answerable for any loss or damage which may happen to them, while they are on their passage to the ship. And it may be laid down as a general rule, that the risk on goods continues no longer than they are actually on board the ship mentioned in the policy; and that if they be removed from on board that ship, and landed, or put on board another ship, without the consent of the insurers, the contract is at an end, and the insurers are discharged from all subsequent responsibility.

To this rule, however, there are several exceptions: as where the ship is disabled, and the goods are put on board another vessel, to be forwarded to their port of delivery; so, if it be agreed, that the goods shall be removed into another ship, at a particular place in the voyage, and no ship being there, they are put on board a store-ship. The insured is protected by the policy in carrying the goods in lighters to any part of the port of delivery, where such goods are usually landed. It is a general principle, that policies ought to be construed according to the usage of trade; and in doubtful cases, in favour of the insured. Although the general rule is, that the insurance on goods shall continue "till they are discharged and safely landed," yet it has been holden by a very eminent and learned judge, that if the insured take goods from on board the ship in his own lighter, the insurer is discharged. Where goods are put into a public lighter, for the purpose of being landed, the risk continues; but if the merchant send his own lighter, this will be a delivery to him, and the insurer is discharged. Although the risk on goods, according to the usual words of the policy, is to continue till they are discharged and safely landed at the port of delivery, this is not to be understood as an authority for prolonging the risk, after the ship's arrival at her port of delivery, for any indefinite length of time, at the pleasure of the insured; but the fair construction of the clause is, that the goods shall remain under the protection of the policy for a *reasonable time*, till they can be conveniently landed, and no longer.

As to the insurance of the *ship*, the risk, in some countries, is made to commence from the time she begins to take in her first goods, or ballast, and to continue till after she arrives at her place of destination, and is entirely discharged. In others, the risk is made to end twenty-one days after the ship's arrival, or sooner, if she be unloaded. In France, if the time of the risk on the ship be not regulated by the contract, it runs from the time she sets sail, till her arrival at her port of destination, and till she be there anchored and moored at the quay. In England, the commencement of the risk on the ship varies in almost every case. In outward-bound voyages, it is generally made to commence from her beginning to load at her port of departure. Sometimes privateers on a cruise, ships engaged in the coasting trade, or in short voyages, are insured for a limited period of time; and, in such cases, the risk commences and ends with the term, wherever the ship may then happen to be. If a ship be insured "from" the port of London to any other port, and before she breaks ground, an accident happen to her, the insurers are not answerable;

## RISK.

for the risk does not commence till the sets fail on her departure from the port of London; but if the insurance be "at and from" the port of London, the insurers are liable for any accident that may happen to her, *from the time of subscribing the policy*. When a ship, expected to arrive at a certain place abroad, is insured "at and from" that place, or "from her arrival" there, the risk begins from the first moment of her arrival at the place specified; and the words "first arrival" are implied, and always understood in policies so worded. In such cases, the risk continues there as long as the ship is preparing for the voyage insured; but if all thoughts of the voyage be laid aside, and the ship be suffered to lie there for a length of time, with the owner's privity, the insurer is not liable; for this would be to subject him to the whim and caprice of the owner, who might choose to let the ship lie and rot there. In English policies, the risk on the ship is usually made to continue "until the ship hath moored at anchor twenty-four hours in good safety," and the insurer is answerable for no loss after the expiration of that time. If the ship, before the twenty-four hours are expired, be ordered to the proper place to perform quarantine, the risk continues, though she do not leave her moorings till long after the expiration of the twenty-four hours. Upon the same principle, if the ship, on her arrival at her port of destination, be subject to seizure under an embargo, and a declaration of reprisals, and she be in fact seized within the twenty-four hours, though she be permitted afterwards to load her cargo, the insurer is liable. The risk on the rigging, tackle, furniture, and provisions of the ship insured, continues no longer than they are attached to, or remain on board, the ship. But if it be necessary to put these articles on shore during a repair, which is the usual practice in such cases, the risk continues on them while on shore, and if they are lost or damaged by any of the perils mentioned in the policy, the insured is liable. An insurance upon an India voyage includes the risk of the country voyage by the usage of the trade, with which, in this and other instances, the underwriter is presumed to be fully acquainted. Thus an insurance was made on a ship "at and from Bengal to any ports or places in the East Indies, China, Persia, or elsewhere beyond the Cape of Good Hope, forwards and backwards, and during her stay at each place, until her arrival at London." In an action on this policy, tried before lord Mansfield, the plaintiff obtained a verdict. Upon a motion for a new trial, the court determined that, under all the circumstances, the plaintiff was entitled to recover. The reasons were, that the underwriters are presumed to know the course of the East India trade, the terms of the charter-party, and the destination of the India ships, (which are under the direction of the company and not of their owners): that the charter-party is a printed form of very long standing: that, besides the liberty thereby given, to prolong the ship's stay for a year, it is very common, by a new agreement, to detain her a year longer; for no ship comes home in ballast, and the longer a ship is kept, the more beneficial to the owners: that the words of the policy are adapted to this usage, being without limitation of time or place, and without any reference to the first voyage particularly mentioned in the charter-party: that the terms of the policy precisely describe the risk in its utmost latitude, and necessarily extend to every prolongation of stay, and every country voyage: that the usage of the India trade, and the course of the voyages in it, were notorious to insurers, who must be supposed sufficiently constant of them, and the obligation of the policy is taken from the usage, and the words of the charter-party, which refer to that usage, in the same manner as if it were expressly inserted in the policy; whereas if every person

insured should be obliged to state to the insurer all the grounds of his expectations, as to the ship's continuance in India, or her returning to England, it might produce great litigation and confusion in cases arising upon these policies: besides, it would be contradictory to the policy, to say that the underwriter did not insure for a country voyage.

If in a policy on an India voyage, there be liberty "to touch, stay, and trade at any ports or places;" this covers the risk, even of a second country voyage. In a like policy, the liberty was only to touch and stay at any port, &c. in the voyage, by the usage of the trade. This covered the risk on the intermediate voyages. Nevertheless, the general rule is, that a liberty to touch and stay at any ports and places, means only places in the usual course of the voyage. A liberty to touch and stay does not authorise the insured to break bulk and trade. If the voyage described in the policy has really been commenced, though at a time, and under circumstances very different from those which were in the contemplation of the parties at the time when the policy was effected; yet if there be no fraud, misrepresentation, or concealment on the part of the insured, this shall be a good commencement of the risk. Although the ship, through necessity, change the order of the places at which she is to touch, yet if she do not abandon the original voyage, the risk continues.

In an insurance upon freight, the risk generally begins from the time when the goods are put on board. If an accident happen to the ship before any goods are put on board, which prevents her from sailing, the insured cannot recover for the loss of freight, which the ship might have earned, if the accident had not happened; but if part of the cargo be put on board, and the rest be ready to be shipped, the insured may recover for the whole freight, upon a valued policy. If the ship be lost on her way to her port of loading, or to a distant place where she is to take in her cargo, the insurer is liable for the whole freight.

If, after the insurance is effected, any thing be done by the insured to alter the nature of the risk, this must be done with the consent of the insurers, otherwise it will avoid the contract. If a ship insured as a private trader afterwards takes letters of marque, without the consent of the underwriters, they are thus discharged, although no use be made of the letters of marque.

In connection with the subject of this article, we may add a few words on the loss, *i. e.* the injury, or damage, which may be incurred by those perils of the sea that constitute the risk, against which the insurer undertakes to indemnify the insured. This loss may be either total or partial; the total loss signifying, in a natural sense, the absolute destruction of the thing insured; but, in a legal sense, it means not only the total destruction, but likewise such damage to the thing insured, though it may specifically remain, as renders it of little or no value to the owner. A loss is also said to be total, when, in consequence of the misfortune that has happened, the voyage is lost, or not worth pursuing; or, if the value of what is saved be less than the freight, &c. A partial loss is any loss or damage not amounting to a total loss. Partial losses are sometimes denominated "average" losses, because they are such as are the subjects of average contributions; and they are distinguished into general and particular averages. These losses may be incurred by the perils of the sea, such as the ship's foundering, stranding, or striking suddenly against a rock, by running foul of another vessel, by fire, by capture, (see RECAPTURE and RANSOM), by arrest and detention of princes, by barratry, (see BARRATRY), by average contributions, by expence of salvage, or they may be wilful and fraudulent. The term *average*, derived from *averagium*, formed

formed from the verb *averare*, to carry, has been explained under that article. It is here used to signify a contribution made by the owners of the ship, freight, and goods on board, in proportion to their respective interests, towards any particular loss or expence sustained for the general safety of the ship and cargo; so as that the particular loser may not be a greater sufferer than the owner of the ship and the other owners of goods on board. This just and equitable contribution is called *general* or *gross average*, because it falls generally upon the whole or gross amount of the ship, freight, and cargo; and also to distinguish it from what is often, though improperly, termed *particular average*, but what, in reality, means a particular, and not a general loss, and has no affinity to average properly so denominated. The *petty* and *accustomed* averages are such as pilotage, towage, light-money, beaconage, anchorage, bridge-toll, quarantine, river-charges, signals, instructions, cattle-money, pier-money, digging the ship out of the ice, &c. When these petty charges are incurred in the usual course of the voyage, they are not considered as a *loss* within the meaning of the policy, but only a necessary and ordinary expence; but if incurred for any extraordinary purpose in the voyage, as to provide against any impending danger, or in consequence of the ship's being driven out of her course by stress of weather, they will then be deemed gross or general average, for which the insurer will be liable. A contribution upon a general average can only be claimed when the sacrifice, occasioning the loss, was, after due deliberation, found to be indispensably necessary for the preservation of the ship and cargo, whenever it appears to have conduced to this purpose, and when the ship and rest of the cargo were actually saved. If goods put into lighters to enable a ship to get up a river be lost, the rest shall contribute; but if the ship be lost, the goods in the lighters shall not contribute. It has been said that the wages and expences of the crew during the detention of a ship unjustly captured, as well as the charge of reclaiming her, and that the charges of wages, &c. upon a ship that is obliged to go into port to rest after a storm, should be brought into a general average. This point has never been decided in a court of justice, but the principle seems to have been allowed by judges of great authority in cases that have occurred.

No injury occasioned by mere sea-damage can be the proper subject of a general average: as if the ship be damaged in her hull or her rigging, the goods on board shall not contribute; also, if a ship spring a leak in a storm, by which goods on board are spoiled, this is a simple damage, or particular loss, and cannot be the subject of an average contribution.

The rule with regard to average contribution seems to be, that the ship, freight, and every thing remaining on board that can properly be deemed a part of the cargo, shall be subject to this charge; and therefore money, plate, and even jewels, must contribute according to their value. But the persons on board, their wearing apparel, and also the jewels and ornaments belonging to their persons, shall not contribute; neither are seamen's wages liable to contribution. When the captain arrives at his port of destination, it is his duty to settle the contribution; and the average, if not settled before, should be paid before the cargo is landed: for the owners of the ship have a *lien* on the goods on board, not only for the freight, but also to *answer all averages and contributions* that may be due. If he neglect his duty in this respect, Mr. Serjeant Marshall conceives that an action would lie against him, or against the owners. If the loss was in money paid, an action on the case for money paid would unquestionably lie against each person bound to con-

tribute for his share; if in goods, a special action on the case, founded on the custom of trade, would lie against each person liable to contribute; or a bill in equity might be filed against them all. The mode of ascertaining each person's contribution, though not very accurately defined, is usually effected by ascertaining, after the ship's arrival at her port of discharge, the neat value of the ship, freight, and cargo, as if nothing had been lost; and valuing these at the price they would fetch in ready money at the port of discharge; and the neat amount, after deducting all charges, is the sum which is subject to the contribution; and each person's share of the loss will bear the same proportion to the value of his property, as the whole loss bears to the aggregate value of the ship, freight, and cargo. In England, some persons make the ship contribute for her full value and the freight; others, for half her value and one-third of the freight; and others, again, for half the value of the ship and freight: and she shall be valued at the price she was worth on her arrival at her port of delivery. The freight is valued at the sum the ship has earned on her arrival there.

As to the mode of valuing the jettison, it is now the settled practice with us to estimate the goods lost at the price they would have fetched at the port of delivery, on the ship's arrival there; freight, duties, and other charges being deducted. These contributions, under the general words of the policy, are a charge which the insurer is bound to pay; and it makes no difference whether the insured pay towards, or receive, this: he ought, in either case, to bear the proportion of the general loss, and that must fall on the insurers. For the loss by expence of salvage, see *SALVAGE*.

With regard to cases of wilful and fraudulent losses, the stat. 1 Ann. st. 2. c. 9. § 4 and 5. makes it a simple felony to destroy any ship, to the prejudice of the owners of the ship or goods on board; and takes away clergy, if committed on the high seas. And the 4 Geo. I. c. 12. extends this to the case of the owner or master who shall destroy any ship, to the prejudice of the owners of, or underwriters upon, goods. The 11 Geo. I. c. 29. takes away clergy from such offenders in all cases. See *PIRATE*.

In cases where the insured is entitled to call upon the insurer as for a total loss, he must "abandon;" that is, he must renounce and yield up to the insurer all his right, title, and claim to what may be saved, and leave it to him to make the most of it for his own benefit. The insurer then stands in the place of the insured, and becomes legally entitled to all that can be rescued from destruction. The idea of "abandonment," therefore, presupposes a total loss in this latter sense, and implies that something remains which may be saved, and which may be given up, or abandoned to the insurers. For if the insured could only abandon, in the case of a total loss, in the strict and natural sense of the words, there would be nothing to abandon, and abandonment would then be only an useless form. Some have said that the practice of abandoning dates its origin from the period when the contract of insurance itself first came into use; and yet it does not seem to be a right which necessarily results from the nature of the contract. It seems more probable that abandonment arose from the practice of occasionally introducing into policies particular stipulations, that if the thing insured should be spoiled, or greatly damaged, by any of the perils insured against, it should be abandoned to the insurers, who should be thereupon obliged to pay the entire sum insured; and that simply making good the damage should not be sufficient to discharge them: and such stipulations, being frequently introduced into the contract,

tract, became at length the foundation of general rules, which have been established in some countries by positive law, and adopted in others as part of the general law of insurance. In the first case of abandonment, that came before lord Hardwicke in the court of chancery, in the year 1744, he determined that where a recaptured ship and cargo were sold to pay the salvage, the insured had a right to abandon the surplus, and claim as for a total loss.

By the law of insurance, as understood in England, the insured may abandon in every case, where, by the happening of any of the misfortunes or perils insured against, the voyage is lost, or not worth pursuing, and the projected adventure is frustrated; or where the thing insured is so damaged, as to be of little or no value to the owner; or where the salvage is very high; or where what is saved is of less value than the freight; or where further expence is necessary, and the insurer will not undertake, at all events, to pay that expence, &c. The ordinance of the marine of Lewis XIV. confines abandonment to the following five cases: capture, shipwreck, stranding, arrest of princes, or the entire loss of the effects insured. By the French law, the right to abandon seems to depend on the "species of misfortune" which has happened: with us, it depends rather on the "degree of loss" sustained in consequence of it. These general principles have been exemplified in cases comprehending losses by capture and arrest of princes, and also other losses. Capture, or arrest of princes, is, *prima facie*, a total loss; and immediately upon the capture, or mere arrest, or at any time while the ship continues under detention, the insured may abandon, and give notice to the insurer of his intention to do so; and thus entitle himself to claim as for a total loss from the insurer. There is, however, this difference between a policy *upon interest*, and a *wager* policy, that, in the one case, the insured may, if he think proper, abandon the moment he has notice of a capture or detention; and this will bind the underwriters, whatever may be the ultimate fate of the ship. But in the case of a *wager* policy, there can be no abandonment, because the insured has nothing to abandon. Nevertheless, a capture or arrest does not necessarily terminate in a total loss: for if a captured ship be retaken, and permitted to proceed on her voyage, so that she suffers but a small temporary inconvenience, this would only be a partial, and not a total loss. Neither does a recapture necessarily deprive the insured of the right to abandon. The rule is, that if the thing insured be recovered before any loss is paid, the insured is entitled to claim as for a total, or a partial loss, according to the final event; that is, according to the state of the case at the time he makes his claim. But if, after a total loss has been actually paid, the thing insured be recovered, the insurer cannot oblige the insured to refund the money he has received; but he shall stand in the place of the insured: thus no injustice is done. Two cases are adduced to shew that, though a captured ship be recaptured, yet if the voyage be lost, the loss will be total, and the insured will have a right to abandon. In one case, a ship is taken and retaken, and sold in a distant country to pay the recaptors for the salvage, and the residue of the produce of the sales remains in the court of admiralty there; and in this case the insured may abandon, and recover as for a total loss. In the second case, a ship, after throwing part of the cargo overboard in a storm, and being disabled from proceeding on her voyage, till refitted, was captured, and her crew taken out; but, after being eight days in possession of the enemy, was recaptured, and carried into an English port; upon which the insured gave notice to abandon. Before the ship could

be refitted, the rest of the cargo was spoiled. This was a total loss, and the insured entitled to abandon. A title to restitution, arising from recapture, cannot take away a vested right to abandon, if the ship is unfit to perform the voyage. Serjeant Marshall observes, that he cannot find a single book, ancient or modern, which does not say that, in case of a ship *being taken*, the insured may demand as for a total loss, and abandon; and the proposition is proved more strongly by the general law which warrants him to abandon, in the case merely of arrest, or an embargo, by a prince not an enemy. If, indeed, the capture proves but a small temporary hindrance, the insured cannot abandon. The insured is in no case obliged to abandon; but he may abandon, if the voyage be defeated, or not worth pursuing: nevertheless he cannot, merely by abandoning, turn a partial into a total loss. It is not universally true, that because a ship has once been captured, the insured may abandon at any time afterwards. The rule is, that if the thing insured be recovered before any loss is paid, the insured is only entitled to a partial or a total loss, according to the final event. By the marine law, the property was not changed by the capture, till after condemnation; but since the 29 Geo. II. c. 34. the "*jus postliminii*" continues for ever. While the ship is in the hands of the enemy, she is considered as totally lost; yet the property is not changed, but reverts to the original owner, upon a recapture. But a recapture does not, in all cases, prevent the loss being total. If the voyage be absolutely lost, or not worth pursuing; if the salvage be very high; if further expence be necessary; if the insurer will not engage, at all events, to bear that expence, though it should exceed the value, or fail of success:—under these, and many other similar circumstances, the insured may disentangle himself, and abandon, notwithstanding a recapture. Upon a recapture, the property returns to the original owner, pledged for the salvage. Although there has at one time been a total loss, yet the insured cannot abandon, after the *final event* has determined it to be only a partial loss at the time of the action brought. There is no vested right to recover as for a total loss, till the insured, having a right to abandon, elects to do so. If the thing insured be recovered before the loss is paid, the insured can only recover according to the final event. If a ship be recovered after a long detention, it is not a total loss, even upon a *wager* policy. When the ship is safe, and the voyage is not lost, the insured ought not to be permitted to abandon. The insurer ought never to pay less than the value of the loss, nor the insured receive more. The insured can only recover an indemnity for his loss, at the time of the action brought, or offer to abandon. If, after a total loss has been paid, the ship be restored, the insured shall not be obliged to refund the money, and take the ship or goods. If, upon a recapture, the captain sell the ship and cargo, as being the best course to take for all parties concerned, the insured may abandon, and recover as for a total loss. If the captain purchase the ship from the captors, for account of his owners; the money paid, being in nature of a salvage, is only a partial loss.

There are other cases, besides capture and arrest of princes, in which the right of abandoning may be considered. Shipwreck is generally a total loss; but the mere stranding of the ship is not, of itself, deemed a total loss, so as to entitle the insured immediately to abandon. It is a rule that, to entitle the insured to abandon, there must have been, at some period of the voyage insured, or during the continuance of the risk, a total loss, and cases have occurred, from which it appears that no partial loss, however great,

## RISK.

occasioned by the perils of the sea, can be turned into a total loss. But if the voyage be lost, from whatever cause, it is a total loss, not only of the ship and freight, but also of the cargo, if no other ship can be procured to carry it to its port of destination. If a cargo be damaged so as to be reduced in value to less than the freight, it will be a total loss.

Another circumstance to be here considered is the time within which the insured may abandon. In France, Spain, and Holland, the times are limited by law, according to the distance of the place where the loss happens, within which the abandonment must be made. In England no time is limited by law for abandoning; but our courts have laid down a rule, which seems better suited to the practice of commerce, and more likely to prevent frauds than those just alluded to. This rule is, that as soon as the insured has received advice of a total loss, he must make his election whether he will abandon or not; if he determines to abandon, he must give the underwriters notice of this "within a reasonable time" after the intelligence arrives; and any unnecessary delay in giving this notice will amount to a waiver of his right to abandon, for unless the owner does some act, signifying his intention to abandon, it will be only a partial loss, whatever may be the nature of the case, or the extent of the damage. When the insured has determined to abandon, and to demand as for a total loss, he is not obliged, as in some foreign countries, to make a formal protest, but merely to give notice of the loss to the underwriters, and of his determination to abandon. But there is no particular form for this purpose; in whatever form an abandonment is declared, it must be explicit, and it is not to be taken as matter of inference from an equivocal act. The notice may be given either to the underwriter himself, or to the agent who has subscribed for him. If the insurance be entire, the insured cannot abandon for part only; but if different articles be separately insured, or separately valued, any one of them may be abandoned. The abandonment must be simple and unconditional, otherwise it will not transfer the entire property to the insurers, which constitutes the essence of the abandonment. If, therefore, I abandon a captured ship, on condition that in case she shall be released, she shall continue my property, and I shall repay with interest the sum which the insurers shall have paid me, such an abandonment would be void.

As to the effect of an abandonment, we observe that it transfers the property insured to the insurers in proportion to their respective subscriptions; and this transfer relates back to the commencement of the voyage. As in England freight is insurable separately from the ship, the abandonment of the ship does not, as in France, transfer to the insurer the freight she has earned. Where the interest of the insured is not entirely covered by the insurance, he may abandon to the extent of the sum insured; for he is his own insurer for the residue. If goods be partly insured, and money borrowed on respondentia for the residue, the insurer will have the legal title to what is abandoned, and the lender only an equitable claim to his proportion. If there be three insurances; one on the ship and cargo, one on the ship only, and one on the cargo only; Emerigon thinks, that the insurers on the ship and cargo have an equal claim on the effects saved, with the insurers on the cargo only, and that they have a like claim on the freight, and the remains of the ship, with the insurers on the ship only, in proportion to their respective subscriptions; e. g. If a ship be valued at 5000*l.*, the cargo 5000*l.*, making a total of 10,000*l.*, and these are insured by different policies, thus:

On ship and cargo	-	-	£3000
On the ship only	-	-	3000
On the cargo only	-	-	3000
Uninsured	-	-	1000
			10,000

A shipwreck happens, and the net proceeds of the wreck of the ship are 500*l.*, and of the cargo 500*l.*, total 1000*l.*; Emerigon would adjust the claims of all parties thus:

To the owners for their part of ship and cargo uninsured,	-	-	£100
To the insurers on ship and cargo, a moiety of the produce of the wreck,	-	-	225
The like to the insurers on the ship,	-	-	225
To the insurers on the cargo, a moiety of the produce of the goods saved,	-	-	225
The like to the insurers on the ship and cargo,	-	-	225
			1000

By this adjustment the insurers on the ship and cargo would have a double share of the effects abandoned, which is manifestly unjust. An English merchant would, we conceive, adjust the different claims thus:

To the owners for their part of ship and cargo uninsured,	-	-	£100
To the insurers on ship and cargo, a moiety of three-fifths of the produce of the wreck,	-	-	150
To the insurers on the ship, three-fifths of the produce of the wreck,	-	-	300
To the insurers on the cargo, three-fifths of the produce of the goods saved,	-	-	300
To the insurers on the ship and cargo, a moiety of three-fifths of the produce of the goods saved,	-	-	150
			1000

The abandonment does not only entitle the underwriters to all that can be saved of the effects insured; but if compensation be made to the insured for the injury from which the loss arose, this compensation shall go to the underwriters; for when they have paid the loss, they, and not the insured, are the real sufferers.

If, after a total loss happening, the ship be abandoned, but she afterwards arrives safe, this shall not avoid the abandonment; but the insurers shall have all the profit of the voyage. But they cannot compel the insured to take back the thing insured and refund the money.

An abandonment once properly made upon a sufficient ground, and accepted by the insurers, is absolute and binding upon both parties; nor can it be revoked but by mutual consent; but if it be not upon sufficient ground, it will be void.

In case of misfortune, the insured is bound to use his endeavours to save as much as possible; and to enable him to do this, without prejudicing his right of abandonment, our policies make several provisions for certain acts to be performed for this purpose, without prejudice to the insurance, "to the charges of which, the insurers agree to contribute, each according to the rate and quantity of his subscription." The captain, in particular, is to exert himself to the utmost of his power in the preservation both of the ship and cargo; and for whatever is recovered of the effects insured, he is accountable to the insurers.

We shall here subjoin a few remarks on the adjustment of losses. In the adjustment of a loss, the first thing to be considered is how to ascertain the "quantity of damage" for which the underwriters are liable; and the next point to be settled is by what rule this shall be "appretiated." In order to ascertain the quantity of damage, the insured ought to know whether the loss be total or partial; if it be total, and the policy is a valued one, the insured is entitled to receive the whole sum insured, subject to such deductions as may have been agreed, by the policy, to be made in case of loss. On a valued policy, the value is admitted, and the insured has only to prove, if the insurance was on goods, that the goods valued were on board. Upon an open policy, it is moreover necessary to prove the value of them, for which value (not exceeding the sum insured) the insurers are responsible. But in the case of a partial loss, the indemnity, secured by either sort of policy, is, that if the thing insured do not come safe to the destined port, but is lessened in value by damage received in the voyage, the loss shall be borne by the insurer. When the loss consists in the total loss of one entire individual parcel of the goods insured, and this is capable of a distinct valuation; as if, out of 100 hogsheads of sugar, 10 are lost, the insurer must pay the value of the 10. When a part of the goods insured is saved, and this exceeds the amount of the freight, the practice is to deduct the freight from the salvage, and to make up the loss upon the difference. But where the freight exceeds the salvage, then it is a total loss. Where the goods insured are damaged in the whole or in part, it is necessary to ascertain the quantity of such damage, by taking the value of the damaged goods from the prime cost, and the remainder will be the amount of the loss. If several articles be insured for one entire sum, but with a distinct valuation to each, and only one be put in risk; if that one be lost, the insured shall recover such a proportion of the sum insured as the value of the article bore to the value of the whole. If there be a clause in the policy, to be free of average from a particular risk, under so much *per cent.*, and a loss occasioned by that risk takes place, the proportion which the loss bears to the cargo must be calculated upon the cargo which was on board when the loss happened, not upon that which was on board at any other time.

In appretiating the loss, averages are settled according to the price of the articles at the time of settling. This is the rule of the Rhodian law, and of the laws of Wisbuy. In France, where almost all policies are valued, the insured has his election to fix the previous valuation, either at the prime cost, or at the current price at the time and place of loading. The same rule that applies to goods, applies also to the ship, which is always valued at the sum she is worth at the time of her departure, or at least at the commencement of the risk. Goods brought from a distance, may be valued at their improved price; but in France it is usually stipulated in the policy, that the ship shall remain of the same value during the voyage.

In England, if the policy be an open one, it is an invariable rule to estimate a total loss at the prime cost of the goods; that is, the invoice price, and all duties and expences till they are put on board, together with the premium of insurance. A ship is valued at the sum she is worth at the time she fails on the voyage insured, including the expences of repairs, the value of her furniture, provisions and stores, the money advanced to the sailors, and, in general, every expence of the out-fit, to which is added the premium of insurance.

A partial loss, upon either ship or goods, is that proportion of the prime cost, which is equal to the diminution

in value occasioned by the damage. And in a case which occurred with regard to a valued policy upon goods, it was determined that the diminution in value was that proportion of the value, in the policy, which the difference between the price of the found, and the price of the damaged, bore to the price of the found in the port of delivery. An insurer is never to be involved in the rise or fall of the market.

An adjustment being indorsed on the policy, and signed by the underwriters, with a promise to pay in a given time, is *primâ facie* evidence against them, and amounts to an admission of all the facts necessary to be proved by the insured to entitle him to recover in an action on the policy. It is like a note of hand, and being proved, the insured has no occasion to go into proof of any other circumstance. An adjustment, however, may be impeached by shewing that the underwriter was induced to sign it by some fraud or concealment, or by some misconception of the law or fact. Marshall's Treatise on the Law of Insurance. See POLICY, RECAPTURE, and WARRANTY.

In matters of insurance, it is a maxim, that all is never to be risked on one bottom, or in the same vessel; to denote, that insurers must act with discretion in the signing of policies, and not hazard too much on each vessel; there being more to be expected from several than from one.

RISKUPITZ, in *Geography*, a town of Moravia, in the circle of Znaym; 9 miles W. of Krumau.

RISÖER, a sea-port town of Norway, in the province of Christianland, on a peninsula projecting into the North sea; 52 miles N.E. of Christianland. N. lat. 58° 43'. E. long. 9° 29'.

RISOLUTIONE, Ital. in *Musick*, the resolution of a discord. See DISCORD, and PREPARATION.

RISOLUTO, Ital. resolved solution, as of a close canon by putting it in score, or by signs.

RISORIUS NOVUS, in *Anatomy*, a name given by Santorini to a muscle, formed of that part of the quadratus genæ which arises from the cheek. See QUADRATUS *Genæ*.

RISPOSTA, or RIPOSTA, Ital. an *answer*, whether in a dialogue or to a regular fugue. For the bringing in the answer to a fugue agreeable to the rigid laws established by the fathers of the science, the old ecclesiastical composers, there are many rules to be observed. See FUGUE.

RISS, or RUSS, in *Geography*, a river of Germany, which passes by Biberach, and runs into the Danube, about six miles above Ulm.

RISTI, a town of Sweden, in the province of Cajana; 25 miles N.E. of Cajanaborg.

RISTIGOUCHE RIVER, a river of Canada, which runs into Chaleur bay, navigable for ships 20 miles from its mouth. It abounds with salmon and wild fowl. On its N. bank, near its mouth, is an Indian village.

RISTORFF, a town of Austria, near Schwannstadt.

RISVIGLIATO, Ital. in *Musick*, when applied to a gay and lively movement succeeding one that is sorrowful, implies vivacity and spirit.

RISUM, in *Geography*, a town of East Friesland; 6 miles W. of Emden.

RISUS. See LAUGHTER, and LUNGS.

RISUS *Caninus* is a kind of laughter in which the lips are contracted, so as to shew all the teeth.

RISUS *Sardonius*, Sardonian laughter, is a forced, spiteful laughter; or a laughter that does not go beyond the teeth.

The phrase is by some said to be founded on this, that in Sardinia there is a venomous plant, which occasions such a contraction of the muscles of the face in persons it kills, that they seem to die laughing in this manner.

**RISZOW**, in *Geography*, a town of Poland, in the palatinate of Kiev; 30 miles N.E. of Bialacerkiev.

**RITA**, a town of Brasil, in the government of Goyas; 80 miles E. of Villaboa.

**RITARDATO**, and **RITARDANDO**, Ital. in *Music*, is relating the measure; better expressed now by *rallentando*, which see.

**RITCHEL**, in *Geography*, a branch of the river Indus, which separates a little above Tatta, and runs into the Arabian sea, N. lat.  $24^{\circ} 15'$ . E. long.  $66^{\circ} 43'$ .

**RITE**, **RITUS**, in *Theology*, denotes the particular manner or form of celebrating or performing the religious ceremonies, which obtains in this or that place.

The eastern people, Armenians, &c. celebrate divine service according to the Greek rite. The western world follow the Latin rite; or that of the Roman church.

The English observe the rite of the church of England, prescribed in the book of Common Prayer, &c.

**RITHER**, or **RIDER**, in *Mining*, is a stone or thin clift that lies in the vein; the ore sometimes runs on both sides it. Sometimes the rither is so thick, that it parts the vein, and makes one vein two.

**RITIA**, in *Ancient Geography*, *Sheebah*, a town of the interior of Africa, in Mauritania Casariensis, situated S. of Victoria. It is mentioned by Ptolemy; and still exhibits some fragments of Roman walls.

**RITORNELLO**, or **REFRET**, in *Music*, the burden of a song, or a repetition of the first or other verses of the song, at the end of each stanza or couplet.

The word is Italian, and signifies properly a *little return*, or a short repetition, such as that of an echo, or of the last words of a song; especially when the repetition is made after a voice, by one or more instruments.

But custom has extended the use of the word to all symphonies, played before the voices begin, and which serve by way of prelude or introduction to what follows.

In the partitions or score of the Italian music, we frequently find the ritornellos signified by the words *si fissa*, to shew that the organ, harpsichord, piano-forte, or the like, are to repeat what the voice has been singing.

In accompanied recitatives, the ritornels, or interstitial symphonies, are not repetitions of vocal passages; but are often beautiful and picturesque periods of symphony, expressive of the sentiments and situation of the singer.

**RITRO**, in *Botany*, corrupted, as it seems, from the *ῥιτρον* of Theophrastus, as far as can be conjectured, appears to have been some plant of the thistle kind. The name is now used as the specific appellation of a kind of *Echinops*; see that article.

**RITROGRADO**, Ital. in *Music*. See *RETROGRADO*.

**RITSCHA**, in *Geography*, a town of Bohemia, in the circle of Kaurzim; 12 miles S.E. of Prague.

**RITSCHENHAUSEN**, a town of Germany, in the county of Henneberg; 3 miles S.S.E. of Meinungen.

**RITSCHIEN**, a river of Stiria, which runs into the Lauffnitz, 4 miles S.E. of Furtenfeld.

**RITSON**, **TRISTRAM**, in *Biography*, born about the year 1580, at Winscott, in Devon, was educated at Great Torrington, and by his rapid progress in learning he very soon became fitted for the higher improvements of the university of Oxford, of which he was admitted a member, being entered probably of Exeter or Pembroke college, about the latter end of the reign of queen Elizabeth. At Oxford he was much distinguished for his learning, and his accomplishments as a gentleman. He, however, appears to have left college without taking any scholastic degree, and retired into his own country, which, according to his biogra-

pher, was probably owing to the death of a sister, upon which he became possessed of the estate of Winscott. Here he drew up a large volume, entitled "The Chorographical Description or Survey of the County of Devon, with the City and County of Exeter, containing Matter of History. Antiquity, Chronology, the Nature of the Country," &c. It was begun in 1605, and finished in 1630.

The author did not print this Description, but a great many manuscript copies were long in circulation in the county. A mutilated edition of it was printed in two volumes 8vo. in 1714; it was afterwards printed from the original in one volume 4to. in 1735. But the most perfect and valuable edition was published in 1811, from a manuscript edition in the possession of John Coles, esq. of Stonehenge; to which the editors made some important additions, and prefixed, as an introduction, which renders the volume much more interesting, "Remarks on the present State of the County of Devon," the object of which was to compare the present and past conditions of the county in those particulars to which the author directed his attention, and to add a brief account of such subjects as either escaped his notice, or have acquired their existence or importance since his time.

Mr. Ritson lived to a great age, dying in the year 1640; he was interred at St. Giles Winscott, without tomb or monument. "He," says Prince in the Worthies of Devon, "that with great expence of money, time, and labour, fought to perpetuate the memory of many persons and families, hath no monument to continue his own; unless that lasting one his "Survey of the County of Devon." See Chorographical Description, ed. 1811.

**RITSON**, **JOSEPH**, was born in 1752, at Stockton on Tees, in the county of Durham, and was brought up to the profession of the law. As a consulting barrister and conveyancer he was very much distinguished; but his literary enquiries were by no means confined within the limits of his profession; he very successfully investigated the old English literature, particularly of the seventeenth century. He died in the year 1803. His works are "Observations on Johnson's and Stevens's Edition of Shakspeare;" "Curious Criticisms on Malone's Edition of Shakspeare;" "Observations on Warton's History of English Poetry;" "Descent of the Crown of England;" "Collection of English Songs, 3 vols. and of Scotch Songs, in 2 vols.;" "English Anthology;" "Metrical Romances," 3 vols.; "Bibliographia Poetica;" "A Treatise on Abstinence from Animal Food;" and other pieces. As an historian, he was rigidly accurate; as a critic, he was uncharitable and severe. The language of his writings is harsh, rugged, and barren; and all his publications are farther disfigured by the affected singularity of their orthography. Monthly Mag. Nov. and Dec. 1803, and Gent. Mag.

**RITTANGEL**, **JOHN-JOSEPH**, a learned professor of the Oriental languages, at Königsberg, in the 17th century. According to some writers he was born of Jewish parents, and educated in the religion of his fore-fathers, but afterwards became a convert to Christianity; others assume that he was a German by birth, and educated in the principles of Popery, and that he became a convert to the institutions of Moses, and received circumcision at Hamburgh, but that in more mature life he embraced the Protestant religion, becoming at first a Calvinist and afterwards a Lutheran. On the authority of a letter given by Bayle, he was a native of Forcheim in Franconia, in the diocese of Bamberg, and brought up to the Roman Catholic faith. Having become a proficient in classical learning, his attention was directed to the study of the oriental languages, and he went to Constantinople, where he remained twelve years, and during that

time had much intercourse with the learned Jews in that city. Upon his return into Germany he embraced the Lutheran religion, and went to Königsberg, where the elector of Brandenburg appointed him professor extraordinary of the Hebrew tongue. He devoted himself now to the illustration of the antiquities of the Jews, and the production of evidence from their writings in support of the truth of Christianity, or of doctrines commonly reputed orthodox. His writings contain severe criticisms on the productions of Kircher, Scaliger, Vorstius, the Buxtorfs, and other learned men, whose proficiency in the Hebrew tongue he affected to hold in low estimation. The time of his death is uncertain, but by a dedication to one of his pieces, it is known that he was living in the year 1652. He was author of the following works: "Liber Jezira, qui Abrahamo Patriarchæ adferibitur, una cum Comment.;" "Liber Veritatis, &c." intended to prove that the ancient Jewish church believed the mystery of the Trinity, and the eternal divinity of the Messiah; and several others.

RITTEBURG, in *Geography*, a town of the county of Mansfeld; 2 miles S.S.E. of Artern.

RITTENHOUSE, DAVID, in *Biography*, a distinguished American philosopher and mathematician in the 18th century, was a native of Pennsylvania, and born in the year 1732. By the dint of genius and application, he was enabled to mingle the pursuits of science with the active employments of a farmer and watch-maker. The latter of these occupations he filled with unrivalled eminence among his countrymen. Some of its nicer operations continued to be his favorite mode of relaxation during all the subsequent periods of his life. In the year 1769, he was invited by the American Philosophical Society to join a number of gentlemen who undertook to observe the transit of Venus; when he particularly distinguished himself by his observations and calculations. He afterwards constructed an observatory, where he made such valuable observations and discoveries, as tended to the general diffusion of science in the western world. During the American war, the philosopher did not claim an exemption from the duties of patriotism; he thought, spoke, and acted like a free man. After the conclusion of it, he successively filled the offices of treasurer of the state of Pennsylvania, and director of the national mint: in the first of which he manifested incorruptible integrity, and in the last, the rare talent of combining theories in such a way as to produce correct practical effects. He succeeded the illustrious Franklin in the office of president of the American Philosophical Society; but towards the close of his days he withdrew from public life, and spent his time in retirement. "There," says one of his eulogists, "we behold him the object of love, admiration, and reverence. In his intercourses of friendship, sincerity and simplicity went hand in hand. A stranger to the too common arrogance of high pretensions, he met every man on the ground of friendly reciprocity. Feeling a superior attachment to those who propagated science, he did not conceal the estimation in which he held them. He was among the first to welcome to America the persecuted philosopher of England (Priestley), and formed with him an intimacy which only required time to be cemented into a lasting friendship." After a very severe illness of a few days' continuance, he died on the 10th of July 1796, about the age of 64. He had the degree of L.L.D. conferred upon him. To the "Transactions" of the American Philosophical Society he contributed several excellent papers, chiefly on astronomical subjects. *Gentleman's Mag.* Sept. 1796. *Monthly Mag.* Oct. 1796.—M.

RITTERA, in *Botany*, named by Schreber in honour

of Dr. John James Ritter, a native of Berne in Switzerland, who practised as a physician, in Silesia, during the middle of the 18th century, and who was the author of various tracts upon Natural History. Schreb. 364.—It is now referred to SWARTZIA; see that article.

RITTERSHUYS, CONRAD, in *Biography*, a learned jurist and philologist, was born at Brunswick in 1560. After having made a great progress in the learned languages, he went to Helmstadt for the study of theology, but his inclination led him to prefer jurisprudence. He removed to Altdorff for the further pursuit of this study, and thence to Ingolstadt. He took the degree of doctor of law at Basil in 1591, and was nominated professor in that science at Altdorff, where he died in 1613. He was the author of "Jus Justinianæum, sive Novellarum Methodica explicatio," 1615, 4to. His philological labours were notes on "Petronius" and "Phædrus;" commentaries on "Salvianus;" on "Oppian de Venatione et Piscatione," with a Latin version; "Guntheri Ligurinus;" "Sacrarum Læctionum, Lib. viii."

RITTERSHUYS, NICHOLAS, son of Conrad, born at Altdorff in 1597, was also a man of learning and a jurist, and particularly applied to historical and genealogical enquiries. He studied at Helmstadt, and afterwards travelled into various countries of Europe. On his return he took a doctor's degree in 1634, and was appointed professor of feudal law at Altdorff. He died in 1670. Nicholas edited several of his father's works, and in 1638 published an oration on "Hanno's Periplus." He was the author of a large folio, entitled "Genealogiæ Imperatorum, Regum, Ducum, Comitum, &c. ab Anno 1400 ad Annum 1664." Several of his letters are printed in the "Epistolæ celeberrimorum Virorum," 1705.

RITUAL, RITUALE, a church-book, directing the order and manner of the ceremonies to be observed in celebrating divine service in a particular church, diocese, religious order, or the like.

The ancient heathens had, likewise, their rituals, or *rituales libri*; those of the Etrurians were much famed. See *ARUSPICI Libri*.

These books contained the rites and ceremonies to be observed in the building of a city, in the consecrating of a temple or an altar, in sacrificing and deifying, in dividing the curiæ, tribes, centuries, and, in general, in all their religious ceremonies.

There are several passages in Cato's books, *De Re Rustica*, which may give us some idea of the rituals of the ancients.

"The principal difference (says bishop Stillingfleet, *Orig. Brit.* p. 287.) between the Roman and Gallic ritual of St. Germanus, which the Britons had adopted before the arrival of St. Austin, was in the *church music*, in which the Romans were thought to excel other western churches so far, that the goodness of their music was the principal incitement to the introduction of their offices."

RITZEBUTTEL, in *Geography*, a town of the duchy of Bremen, on a small river, which runs into the German ocean, between the mouths of the Elbe and the Wefer; 38 miles N. of Bremen. N. lat. 53° 52'. E. long. 8° 37'.

RITZENBUTTEL, a town of the duchy of Bremen. RITZENBUTTEL, or *Ritzbuttle*, is a small town, containing about 200 houses, half a mile from Cuxhaven, with a castle garrisoned by Hanoverians. The road for foot-passengers, from Ritzbuttle to Cuxhaven, is on a causeway, raised about eight feet from the carriage-road; but being made of clay, it is, in wet weather, extremely dirty and slippery. The road for carriages is very bad. The part

of Cuxhaven having only two or three small hovels, and a wind-mill, the passengers by the packets reside during their stay at Ritzbuttle.

**RIVA**, or **RIFF**, a town of the county of Tyrol, at the end of the Garda lake; 16 miles W.S.W. of Trent.—**Alfo**, a river of the Tyrolese, which runs into lake Garda, near the town of the same name.—**Alfo**, a town of France, in the department of the Po, seated on an eminence, in the middle of a plain, which extends to the W. and S., and is nearly surrounded with water, over which are two bridges, one of wood, the other of stone. The adjacent hills are covered with vines and fruit-trees, and the plain produces abundance of grain; most of the houses within the walls are furnished with gardens; two miles E. of Chieri.—**Alfo**, a town of Italy, in the bailiwick of Lugano; 8 miles S. of Lugano.—**Alfo**, a town of Italy, in the Valteline; 6 miles S. of Chiavenna.—**Alfo**, a town of Italy, in the department of the Mela; 14 miles N.N.W. of Brescia.—**Alfo**, a town of the Ligurian republic; 6 miles N.N.E. of Savona.

**RIVAGE**, **RIVAGIUM**, a toll anciently paid to the king on some rivers, for the passage of boats or vessels therein.

**RIVAL**, **RIVALIS**, a term of relation applied to two persons who have the same pretension.

It is properly used for a competitor, in love; and figuratively, for an antagonist in any other pursuit. The intrigues of comedies and romances usually turn on the jealousies of rivals, who dispute for the same mistress.

The lawyers derive the word from the Latin *rivus*, *stream*, *quod ab eodem rivo aquam hauriant*.

Donatus supposes it to have been formed hence, that beasts coming to drink at the same brook, or fountain, frequently quarrel.

Cælius says, that rivales were originally such whose fields were parted by a brook or rivulet, the course of which being liable to be varied several ways, occasioned frequent disputes and law-suits.

**RIVALTA**, in *Geography*, a town of France, in the department of the Po, on the Sangon; 6 miles S.W. of Turin.—**Alfo**, a town of Italy, in the department of the Olona; 15 miles E. of Milan.

**RIVANNA**, a river of Virginia, which unites with the Fluvanna, to form James river, about two miles above Elk island. It is navigable for canoes and batteaux, to its intersection with the S.W. mountains, about 22 miles.

**RIVAROLI de Fuori**, a town of Italy, in the department of the Mincio; 20 miles S.W. of Mantua.

**RIVAROLO**, a town of France, in the department of the Po, on the Orco; 15 miles N. of Turin.

**RIVAUT**, **DAVID**, in *Biography*, a French man of letters and various writer, was born at Laval, in the province of Perche, about the year 1571. He was brought up in the family of the count de Laval, and for some time followed the military profession, serving in Italy about the close of the 16th century, and in Holland in the year 1602. During the following year, Henry IV. appointed him one of the gentlemen of his bed-chamber. In 1605 he accompanied the young count de Laval into Hungary, and entered into the service of the emperor against the Turks. On his return to his native country, he devoted himself to literary and scientific studies, in which he had before made considerable progress. In 1611 he was appointed sub-preceptor to the young king Lewis XIII., and had a pension of 3000 livres settled upon him. The office of principal preceptor becoming vacant during the next year, he received that appointment, and was honoured with the title of counsellor of

state. In 1614, the king conferred on him letters of nobility. He died at Tours, in 1616, about the age of 45. He is spoken of with high esteem by several of the most celebrated writers of his time, particularly by Casaubon, Scaliger, Vossius, Erpenius, and Menage. His works consist of "The States, or a Discourse concerning the Privileges of the Prince, the Nobles, and the third Estate," &c.; "Elements of Gunnery," which is a curious and very scarce work; "Archimedis Opera quæ extant, Græcè et Lat. novis Demonstrationibus illustrata;" &c. folio, and other pieces.

**RIVE de Gier**, in *Geography*, a town of France, in the department of the Loire, and chief place of a canton, in the district of St. Etienne; 4 miles N.E. of St. Etienne. The place contains 4263, and the canton 15,089 inhabitants, on a territory of 160 kilometres, in 13 communes.

**RIVEL de les Semals**, a town of France, in the department of the Aube; 9 miles W.N.W. of Quillan.

**RIVELLES**, a town of Spain, in Catalonia; 12 miles N. of Cervera.

**RIVELLO**, a town of Naples, in the province of Basilicata; 12 miles S.E. of Lauria.

**RIVER**, **FLUVIUS**, or *Flumen*, a stream or current of fresh water, flowing in a bed or channel, from a source or spring, into the sea.

If the stream be not large enough to bear boats, or small vessels, loaden, it is properly called, in English, by the diminutive *rivulet*, or *brook*; by the Latins *rivus*; and by the French *ruivière*. If it will only bear such vessels, the Latins call it *amnus*. If it be considerable enough to carry larger vessels, it is called by the general name *river*; by the Latins *fluvius*, and *flumen*; and by the French *fleuve*; between all which the difference is only as to greater and less.

Some will have none to be properly rivers, except those which bear the same name from their source to their mouth.

Others, none but those which empty themselves immediately into the sea; and not into any other river.

Rivulets have their rise, sometimes from great rains, or great quantities of thawed snow; especially in mountainous places; as in the long ridges of Africa, India, Sumatra, &c. But the generality of rivulets arise from springs.

Rivers themselves all arise either from the confluence of several rivulets, or from lakes; nor is there any great river, such as the Rhine, Elbe, &c. known to flow from a single spring.

The Volga, *e. gr.* consists of above two hundred rivulets, all flowing into it, before it reaches the Caspian; and the Danube receives as many.

The Rhine and the Po receive each above a hundred others, great and small; and the river of the Amazons receives into its large bed a prodigious number, some of which are five or six hundred leagues in length, and are of such a depth and breadth as render them principal rivers.

Pliny, indeed, and Cardan, say, that the Nile receives none; but the later travellers into Abyssinia assure us of the contrary.

The Rhine, Rhone, Danube, Borysthenes, &c. arise originally from springs in the mountains; and the Nile, the Volga, the great river of St. Laurence, &c. from lakes.

It has been held by many, that all springs and rivers owe their origin to rains and dews; but there are some springs which cannot be accounted for on this principle, though others very well may. The intermitting springs, which  
flow

## RIVER.

flow violently in rainy seasons, and are dry in summer, are probably owing to rains; but there are some springs which discharge more water annually than all that falls in rains and dews in the neighbouring country. The great perennial spring, at Willowbrig, in Staffordshire, is of this kind, and that of the Sorgue, in France, is much more eminently so; the river of that name being, according to Gassendus, navigable up to the very springs which are its source.

But if such springs as these discharge too great a quantity of water for the supply of rains and dews, how is it possible, that such small supplies of water as these can afford the constant currents of the larger rivers? The Volga alone, according to Ricciolus, pours forth as much water in a year's time into the Caspian sea, as would suffice to drown the surface of the whole earth. The river of St. Laurence, in America, pours forth nearly as much as this. If either of these rivers alone do, as has been affirmed, from calculations, discharge annually as much water as falls in the same time in rains and mists upon the surface of the whole earth; from whence are all the rest to be supplied, according to the system of their all being made by rains; and, particularly, where is left the supply for the Rio de la Plata, which Ricciolus affirms to be larger than the Nile, the Ganges, and the Euphrates, put together? its mouth being ninety miles wide, and running with that violence into the sea, that it makes it fresh for two hundred miles together. These, and the other rivers of the several parts of the globe, upon a very moderate calculation, discharge at least five hundred times as much water into the sea, as falls upon the whole surface of the earth, in rains, mists, dews, snows, &c. in a like space of time.

As it is evident, therefore, that these cannot be supplied by rains, so neither is it possible that the several hot springs and the salt springs can be supplied that way: the origin of springs also in places where there falls little or no rain, and where the conservatories must needs be too small to contain a supply, are great proofs that rain and mists are not the origin of springs, at least not in all places. The isles of Mago, Rotunda, and the Strophades, and the rock on which the Maiden Tower stands in the Thracian Bosphorus, cannot be supplied with, or retain a sufficiency of rain-water to supply constant springs, yet such are always found running there.

It cannot be otherwise but that there are subterranean communications between the sea and the sources of fountains, rivers, and the larger springs, by which these are supplied; and there are certainly charybdes which swallow the sea for these purposes; and when these happen to be stopped, the largest rivers have been dried up, and wholly ceased to run for a considerable time: this we have accounts in history has happened to the Thames, the Trent, and Medway, in England; the Elve, the Motala, and Gulspang, in Sweden, and other rivers in other countries. If, on the other hand, these charybdes happen to be too open, fresh-water springs depending upon them will become salt. This we have instance of in history also; and even so old a writer as Pliny has said that this once happened in Caria near Neptune's Temple. (Plot. de Origine Fontium.) See EVAPORATION and SPRING.

**RIVERS, Phenomena and Variations of.** Rivers are found subject to great alterations, at different seasons of the year, day, &c. from frequent rains and melted snow. Thus in Peru and Chili many of the rivers are almost insensible in the night-time, and only flow by day, as being then augmented by the dissolution of the snow on the mountains Andes. Thus the Volga abounds in water in May and June, so as

to cover the sand-banks, &c. which all the rest of the year lie bare, so as scarcely to allow a passage to the loaded ships. Thus also the Nile, Ganges, Indus, &c. are frequently so increased, as to overflow; and that either in the winter, from rain, or in the summer, from the melting of the snow. Some rivers bury themselves under ground in the middle of their course, and break out again in other places, like new rivers. Thus the Niger, which some cosmographers erroneously derive by a subterraneous channel from the Nile, because it swells at the same time with the Nile, without any other apparent cause—the Niger itself has been supposed by some to be hidden under the mountains of Nubia, and to rise again on the western side of those mountains; whereas, in reality, it is lost in lakes or sands. Thus, also, the Tigris is lost in the mountain Taurus, &c.

Aristotle, and the poets, mention several such rivers about Arcadia: Alpheus, a river of Arcadia, is particularly famed. This, being swallowed up in the ground, is supposed, by the Greek authors, to continue its progress under the earth, and under the bottom of the sea, into Sicily; where, breaking up near Syracuse, it forms the river Arethusa. The great reason of this opinion was, that, every fifth summer, the river Arethusa, in Sicily, cast up the dung of cattle about the time of the celebration of the Olympic games in Achaia, when the dung of victims was used to be cast into the Alpheus.

Some rivers empty themselves into the sea by one mouth, some by several. Thus, the Danube opens into the Euxine sea by seven mouths; the Nile by seven; and the Volga by at least seventy. The cause of this variety of mouths Varenus attributes principally to the banks of sand, &c. accumulated in them; which, gradually increasing, form islands, by which the channel is divided into several branches. Indeed, the ancients tell us, that the Nile formerly only emptied itself at one mouth, called the *ostium Canopicum*; and add, that the other six are adventitious, or artificial.

The channels of rivers, except such as were formed at the creation, Varenus endeavours to prove to be all artificial, and dug by men. His reasons are, that, when a new spring breaks forth, the water does not make itself a channel, but spreads over the adjacent land; so that the people have been necessitated to cut it a channel, to secure their grounds; and that a great number of channels of rivers are certainly known, from history, to have been dug by men, &c.

As to the question, whether those rivers which run into others, have made themselves that way by their own motion, or have been turned thither in canals cut by men? he takes the latter to be the more probable; and concludes the same of the arms, or branches, of rivers, and of the turns by which islands are formed in the Tanais, Volga, &c.

To the question, why we have no salt rivers, when there are so many salt springs? he answers, that it is because men, having no occasion for salt water, have not dug channels to conduct the water of salt springs; salt being procurable at less expence.

The water of most rivers carries with it particles of metals, minerals, sands, or oily and fat bodies, &c. Thus, some rivers bring sands intermixed with grains of gold; of which kind is, 1. A river in Japan. 2. Another in the island of Lequico, near Javon. 3. A rivulet in Africa, called Arroe, breaking out of the foundation of the mountains of the moon, in which there are golden mines. 4. A river in Guinea, where the negroes separate the gold-dust from the sand, and sell it to the Europeans, who traffic thither for that very purpose. 5. In some rivulets near the city of Mexico, there are grains of gold taken up, especially  
after

after rain; which is also to be understood of all the other rivers, none of which yield any thing considerable, except in rainy seasons. 6. In Peru, Sumatra, Cuba, Hispaniola, and Guinea. Lastly, there are several brooks in the countries about the Alps, especially Tyrol, out of the sediment of whose waters gold has been drawn, though there be no grains conspicuous in them. Add to this, that the Rhine also, in many places, has afforded a golden mud.

As to rivers that bring grains or particles of silver, iron, copper, lead, &c. we find no mention of them in authors, though, doubtless, there are great numbers of each; and many of the medicinal effects of mineral waters are, doubtless, owing to particles of these kinds.

We must not here omit a water in Germany, which is ordinarily supposed to change iron into copper. The truth is, there is no real conversion of the metal; all that is done is, that the cuprine and vitriolic particles in the water corrode the iron; and, detaching parts of them by means of the motion of the water, coppery particles succeed in their room.

From this variety in the mixture of river-water result various qualities, different specific gravities, different colours, &c.

Some rivers, at certain seasons of the year, swell so as to overflow their banks, and drown the neighbouring lands. Of these the most eminent is the Nile, which rises so as to cover all Egypt, except the hills. The inundation begins about the seventeenth day of June, and increases for the space of forty days, and decreases for as many; during which period, the cities of Egypt, which are all built on hills, appear as so many islands.

To these inundations Egypt owes all its fertility; the heavens there affording no rain, or at least none in any respect considerable. Hence, as the inundation is great or small, Egypt, for that year, is fruitful or barren.

The ancient Greeks, &c. were much perplexed in assigning the cause of this inundation. From the modern English and Portuguese traders into Congo, Angola, Monomotapa, &c. we learn, that the source of the Nile is in a large lake called Zaire, round which are the mountains of the moon, which being about  $10^{\circ}$  to the south of the equator, instead of being covered with snow in their winter, have rain every day, at least two hours before, and two hours after noon. So that their tops are always covered with clouds; and the rains are, at the proper season, almost continual. Hence torrents are constantly descending from the mountains into the lake of Zaire; whence they flow into the channel of the Nile, and other rivers arising from the same lake; and hence the inundation of the Nile. See NILE and NILO-METER.

Mr. Bruce is the first person who, in his "Travels to Discover the Source of the Nile," has described, from his own observations, the spot in which he apprehends that the Nile springs.

Tracing one of the streams, that run into the lake Tzana, to a swamp in the 11th degree of N. lat. he there remarks the head of the Nile, as our modern map-makers had actually done before he visited this dreary region. Whether his guide deserved credit, and whether he could justly infer that this rivulet was the Nile from the respect paid to it by the barbarous natives, it is not necessary particularly to enquire. The most important object in investigating the source of the Nile is to account for its extraordinary inundations.

In doing this, Mr. Bruce has selected from the various opinions enumerated by Diodorus Siculus (l. i. c. 24.) that of Democritus of Abdera, and Agatharcides of Cnidus,

which agrees in the main with that of Herodotus (l. ii. c. 8.) and has well explained the manner in which the sun, continuing nearly stationary for some days in the tropic of Capricorn, rarefies the air, and collects a quantity of vapours from the Atlantic on the west, and the Indian ocean on the east; and then, in its progress north towards the tropic of Cancer, draws these vapours after him. So that as he advances, the rainy season begins upon his arrival at the zenith of every place, and the rains continue and increase after he has passed it in his progress northward.

In April many rivers join the Nile, and enable it to force its way through the stagnant lake Tzana, without mixing with it. In the beginning of May many other streams pour themselves into the same lake, and furnish the Nile with an additional supply of water. In the beginning of June, the sun having passed over Abyssinia, the rivers are there full, and the time of the greatest rains in this country is during the sun's being almost stationary in the tropic of Cancer. These rains are collected by the four great rivers of Abyssinia, of which the Nile is one, which derives also a very copious supply from the White river, that rises in a country of almost perpetual rain.

As the vapours meet with no mountains to interrupt their progress in the flat country that lies between Gerri and Syene, the tropical rains extend no farther north of the line than  $16^{\circ}$ .

When the sun declines towards the equator, he reverses the effects which he produced in his passage northward; and after his arrival at the line in the autumnal equinox, his influence ceases on the side of Abyssinia, and extends itself to the southern hemisphere. Thus on the 25th of September, three days after the equinox, the Nile is generally found at Cairo to be at the highest, and then begins to decrease. Mr. Bruce explains the inundations that take place south of the equator. The ancients were not unacquainted with this cause of the inundations of the Nile. The tropical rains falling to the extent of  $16^{\circ}$  on each side of the line gave rise to the Nile and to its tributary streams which flowed northward, through the kingdom of Sennar, &c. as well as to the Zeebe, and many large rivers which flow southward into Ethiopia, and according to the descent of the countries into the Indian or Atlantic ocean. Homer gives to the Nile the epithet *δεξιτερῆς, qui calidus descendit, a river produced and fed by rains.* See NILE.

The other rivers which have any notable stated inundations, are the Gambia, and the Niger, which overflow at the same time with the Nile, and lose themselves in sands or lakes. (See NIGER.) Leo Africanus says, it begins on the 15th day of June, increases for forty days, and decreases as long. The Zaire, a river of Congo, is affected in the same manner with the Nile. (See ZAIRE.) The Rio de la Plata, in Brasil, as Maffeus observes, overflows at the same time with the Nile. (See Rio de la PLATA.) Of the same kind of rivers is the Ganges (which see); and the Indus, both which last overflow in June, July, and August; at which times the natives save great quantities of the water in ponds to serve them the rest of the year; several rivers flowing out of the lake Chiamay into the bay of Bengal, which overflows in September, October, and November: these all bring a very great fertility with them to the ground; the river Macoa, in Camboia; the river Parana, or Paranguasa, which some will have to be the same with the Silver river; several rivers in Coromandel, a part of India, which overflow in the rainy months, from the great quantity of water issuing from the mountain Gatis; the Euphrates, which overflows Mesopotamia certain days in the year; and, lastly, the river Sus, in Numidia.

# RIVER.

The rivers most celebrated for their length, breadth, swift-ness of current, &c. are, the Nile, which runs almost in a straight course two thousand five hundred and twenty geographical miles; the Niger, which runs two thousand four hundred miles; the Ganges, two thousand miles; the Burrampooter, the same distance; the Ob, sixteen hundred miles; the Jennifsee, in Asia, about the same length with the Ob; the river Orellana, in America, sixty miles broad at its mouth, and five thousand miles long; the Rio de la Plata, about ninety miles broad at the mouth; the Omarannan, another river of Brasil; and the great river of St. Laurence, near two thousand five hundred miles long. See the account of each river under its respective name.

Major Rennell, in his "Memoir," has estimated the proportional lengths of course of some of the most noted rivers in the world by the following numbers:

European Rivers.				
Thames	-	-	-	1
Rhine	-	-	-	$5\frac{1}{4}$
Danube	-	-	-	7
Volga	-	-	-	$9\frac{1}{2}$
Asiatic Rivers.				
Indus	-	-	(probably)	$6\frac{3}{4}$
Euphrates	-	-	-	$8\frac{1}{2}$
Ganges	-	-	-	$9\frac{1}{2}$
Burrampooter	-	-	-	$9\frac{1}{2}$
Nou Kien, or Ava	-	-	-	$9\frac{1}{2}$
Jennifsee	-	-	-	10
Oby	-	-	-	$10\frac{1}{2}$
Amoor	-	-	-	11
Lena	-	-	-	$11\frac{1}{2}$
Hoanho (of China)	-	-	-	$13\frac{1}{2}$
Kian Ken (of ditto)	-	-	-	$15\frac{1}{2}$
African River.				
Nile	-	-	-	$12\frac{1}{2}$
American Rivers.				
Mississippi	-	-	-	8
Amazons	-	-	-	$15\frac{1}{2}$

By the statute of Westm. 2. cap. 47, the king may grant commissions for persons to take care of rivers, and the fishery in them; and the lord mayor of London is to have the conservation in breaches and ground overflown as far as the water ebbs and flows in the river Thames. (4 Hen. VII. cap. 15.) Persons annoying the river Thames, making shelves there, casting dung in it, or taking away stakes, boards, timber-work, &c. of the banks, incur a forfeiture of *5l.* by stat. 27 Hen. VIII. cap. 18. Commissioners were appointed to prevent exactions of the occupiers of locks, weirs, &c. upon the river Thames, westward from the city of London, to Cricklade, in the county of Wilts, and for ascertaining the rates of water-carriages on the said river, by stat. 6 & 7 W. III. and this statute is revived, with authority from the commissioners to make orders and constitutions to be observed, under penalties, &c. by 3 Geo. II. cap. 11.

By statutes 8 Geo. II. cap. 20, and 4 Geo. III. cap. 12, it is made felony, without benefit of clergy, maliciously to cut down any river or sea-bank, by which lands may be destroyed, and to destroy sluices or locks upon navigable rivers. See NUSANCE, and LARCENY.

RIVER, in *Physics*, denotes a stream of water running by its own gravity from the more elevated parts of the earth VOL. XXX.

towards those which are more depressed, in a natural bed or channel open above.

If this channel is artificial, it is called a canal; of which there are two kinds, *viz.* that whose channel is every where open without sluices, called an artificial river, and that whose water is kept up or let off by means of sluices, which is properly a canal.

RIVERS, *Hydraulic Theory of.*—The theory of moving waters is certainly one of great importance, and has therefore, for a long time, excited considerable interest, as well among practical engineers, as speculative mathematicians; yet it must be acknowledged that it is but very lately any thing approaching to a well-founded theory has been established. One of the first and most distinguished of those who attempted to reduce the motion and discharges of rivers to correct principles, was Guglielmini; and if his theory was false and hypothetical, yet he was the means of drawing the attention of philosophers to these inquiries; and his deductions, though in many respects incorrect, are nevertheless entitled to a place in an article on this subject.

This author observes, that rivers have usually their sources in mountains or elevated lands, and that it is in their descent from these they acquire their velocity, or acceleration, which maintains their future current. In proportion as they advance farther, this velocity diminishes, on account of the continual friction of the water against the bottom and sides of the channel, of the various obstacles they meet with in their progress, and of their arriving, at length, in plains, where the descent is less; and their inclination to the horizon, of consequence, greater. Thus the Reno, a river of Italy, which gave occasion, in some measure, to these speculations, is found, near its mouth, to have scarcely a descent of fifty-two seconds.

If the acquired velocity be quite spent, through the many obstacles, so that the current becomes horizontal, nothing will then remain to propagate the motion, and continue the stream, but the depth, or the perpendicular pressure of the water, which is always proportional to the depth. And happily for us, this resource increases, as the occasion for it increases; for, in proportion as the water loses of the velocity acquired by the descent, it rises and augments in depth.

It further appears, says he, from the laws of motion pertaining to bodies moved on inclined planes, that when water flows freely upon an inclined bed, it acquires a velocity, which is always as the square root of the quantity or declivity of the bed. But in an horizontal bed, opened by sluices or otherwise, at one or both ends, the water flows out by its gravity alone; and the flowing is quicker or slower in a direct ratio of the respective heights of the water, by reason of the weight of the superior waters upon the inferior. Hence it follows, first, that as much as the declivity of the bed or channel of a river is greater, so much also will the velocity of the flowing waters be proportionally increased.

Secondly, as much as the water in an horizontal bed is deeper, so much will the velocity of the current be increased; and this velocity will diminish in proportion to the decreasing depths of the water in the bed.

Thirdly, abstracting from the resistance caused by the bottom and sides of the bed, as much nearer as the water is to the bottom, so much will its motion be accelerated; not only because the inferior waters are more compressed by the superior in proportion to their greater depth; but also because the inferior ones have a greater declivity than the superior, by reason of their greater depth in the bed, S f where

where they are more depressed with respect to the elevation of their common source or spring.

The upper parts of the water of a river, and those at a distance from the banks, may continue to flow, from the single cause, or principle of declivity, how small soever it be; for, not being detained by any one obstacle, the minute difference of level will have its effect; but the lower parts, which roll along the bottom, will scarcely be sensible of so small a declivity; and will only have what motion they receive from the pressure of the superincumbent waters.

The natural cohesion of the particles of water, and their implication, as it were, with one another, make the lower, which are moved by means of the depth, carry along with them the upper, which, in an horizontal channel, would have no motion at all: or, in a channel very little inclined, next to none; so that the lower, in this case, communicate to the upper a part of the motion they have received from the pressure of it. Hence, from the pressure, it frequently happens that the greatest velocity of a river is about the middle of its depth, or that point, which is the farthest possible from the surface of the water, and from the bottom and sides of the bed; such middle parts having the advantage of being pressed with half the depth of the river, and of being free, at the same time, from the friction of the bottom; whereas, on the contrary, the least velocity of the water is at the bottom and sides of the bed, because there the resistance resulting from friction is the greatest, which is communicated to the other parts of the section of the river, in an inverse duplicate proportion of the distances from the bottom and sides combined together.

To find whether the water of a river, almost horizontal, flows by means of the velocity acquired in its descent, or by the pressure of its depth, set up an obstacle perpendicular to it; if the water rise and swell immediately against such obstacle, it runs in virtue of its fall; or, if it stop a little while first, in virtue of its pressure.

Rivers, according to this author, almost always make their own beds. If the bottom have originally been a large declivity, the water, in consequence of it, falling with a great deal of force, will have swept away the most elevated parts of the soil, and carrying them lower down, will gradually render the bottom horizontal; where the stream is swiftest, there will the earth be most dug up; and, consequently, there the greatest cavity will be made.

The water having made its bed horizontal becomes so itself, and consequently rakes with the less force against the bottom, till at length that force becomes only equal to the resistance of the bottom. The bottom is now arrived at a state of permanency, at least for a considerable time; and the longer, according to the quality of the soil, clay and chalk resisting longer than sand or mud.

On the other hand, the water is continually wearing away the brims of its channel, and this with the more force, as, by the direction of its stream, it impinges more perpendicularly against them. By this means it has a continual tendency to render them parallel to its own course; and when it has arrived as near that as possible, it ceases to have any effect that way. At the same time that it has thus rectified its edges, it has enlarged its own bed; that is, it has lost of its depth, and consequently of its force and pressure: this it continues to do till there is an equilibrium between the force of the water and the resistance of its banks, upon which they will remain without farther mutation. And it is evident, from experience, that these equilibriums are all real, inasmuch as we find that rivers only dig and widen to a certain pitch.

The very reverse of all these things happens on other oc-

casions. Rivers, whose waters are thick and muddy, raise their bed, by letting part of the heterogeneous matters contained in them fall to the bottom: they also contract their banks, by a continual apposition of the same matter, in brushing over them. This matter, being thrown aside far from the stream of water, might even serve, by reason of the obscurity of the motion, to form new banks.

Now these opposite effects seem almost always to concur, and are differently combined, according to the circumstances, whence it is very difficult to judge of the result; yet must this combination be known very accurately, before any measures can be taken about rivers, especially as to the diverting of their courses. The Lamona, which emptied itself into the Po, being turned another way, to make it discharge itself into the Adriatic, was so altered, and its force so far diminished, after its waters were left to themselves, that it raised its bed a great height, by continual depositions of mud, till it became much higher than the Po, in its utmost accretions, and needed very high banks, or dykes, to keep it from overflowing.

If various causes of resistance to the motion of flowing waters did not exist, such as the attraction and continual friction of the bottom and sides, the inequalities in both, the windings and angles that occur in their course, and the diminution of their declivity the farther they recede from their springs, the velocities of their currents would be accelerated to twelve, fifteen, and, in some cases, even to twenty times more than they are at present in the same rivers, by which they would become absolutely unnavigable.

A little river may be received into a large one, without either augmenting its width or depth. This seeming paradox arises hence, that the addition of the little river may only go towards moving the waters, before at rest near the banks of the large one, and thus augmenting the velocity of the stream, in the same proportion as it does that of the quantity of water. Thus the Venetian branch of the Po swallowed up the Ferrarese branch, and that of Panaro, without any enlargement of its own dimensions. And the same may be concluded proportionably of all other accessions to rivers, and, in the general, of all new augmentations of water.

A river offering to enter into another, either perpendicularly, or in an opposite direction, will be diverted by degrees from that direction, and obliged to make itself a new and more favourable bed towards the mouth.

The union of two rivers into one makes the whole flow the swifter, because, in lieu of the friction of four shores, they have only two to surmount; and that the stream, being farther distant from the banks, goes on with the less interruption; besides, that a greater quantity of water, moving with a greater velocity, digs deeper in the bed, and of course retrenches of its former width. Hence also it is that rivers, by being united, take up less space on the surface of the earth, and are more advantageous to low grounds, which discharge their superfluous moisture into them, and have likewise less occasion for dykes to prevent their overflowing.

These advantages are so considerable, that S. Guglielmini thinks them worthy of nature's having had a view to them in her contriving to make the confluences of rivers so frequent as we find them.

Such were the views and deductions of this author, in which he has been followed by several mathematicians of the first eminence; but certainly without coming to any very accurate and established principles, on which to found a computation of the quantity of water that would be discharged, in any new case that presented itself for determination;

tion; or what slope, and what magnitude of current, was necessary for producing any required supply. Thus, a small aqueduct, which was carried to Paris in the beginning of the last century, on a plan presented to the academy, and, with some alteration, approved of by that learned body, was found, when completed, to yield very little more than half the quantity of water which they had computed. A similar circumstance happened at Edinburgh, when that city was supplied by water, under the direction of Desaguliers; the quantity of water actually furnished being only about one-sixth of the quantity which he had computed it would be, and but one-eleventh of what Maclaurin had estimated it at from the same plan.

Nothing can shew more clearly the inadequacy of the theory, as it existed at that time, than that the first mathematicians of their age, and we might almost add of any age, should differ so widely from each other; the estimate of the one being but about one-half of the other, and the nearest to the truth not agreeing with the actual supply by five parts out of six.

It required but a few instances of this kind to point out the necessity of a more precise and definite theory; and the subject was accordingly soon after undertaken by Michelotti at Turin, the abbé Bossut at Paris, and by the chevalier du Buat; of whom the latter is generally admitted to have met with the most complete success. Michelotti made a great number of experiments, both on the motion of water in pipes and in open canals. They were performed at the government expence, and nothing was spared to render them complete. A tower of fine masonry was built, to serve as a vessel from which the waters were to issue, through holes of various sizes, and under various pressures, from 5 feet to 22 feet. The water was received into basons constructed of masonry, and accurately lined with stucco, and of various forms and declivities. These experiments on the expence of water through pipes are, of all that have yet been made, the most numerous and exact, and may be appealed to on every occasion. Those made on open canals are still more numerous, and are no doubt equally accurate; but they have not been so contrived as to be so generally useful, being mostly very unlike the important cases which will occur in practice; and they seem to have been contrived chiefly with a view of overturning or establishing certain received hydraulic principles of that time. The experiments of Bossut are also very numerous, and of both kinds, viz. on pipes and canals; some particulars of which will be found under our article DISCHARGE of Fluids. But those of the chevalier du Buat are the most conclusive, and his theory of rivers the most perfect of any with which we are yet acquainted. A few of the leading principles of this author's theory will be found in the subsequent part of this article.

It is certain that the motion of open streams must, in some respects, resemble that of bodies sliding down inclined planes, perfectly polished; and that they would accelerate continually, were they not obstructed; but they are obstructed, and frequently move uniformly. This can only arise from an equilibrium between the forces which promote their descent and those which oppose it. Hence M. Buat assumes his leading proposition, viz.

1. "When water flows uniformly in any channel or bed, the accelerating force, which obliges it to move, is equal to the sum of all the resistances which it meets with, whether arising from its own viscosity, or from the friction of its bed."

From this proposition, ingeniously combined with the re-

sult of his own and Bossut's experiments, he then draws these fundamental propositions, viz.

2. "The motion of rivers depends entirely on the slope of their surfaces.

3. "Since the velocity of the water depends wholly upon the slope of the surface, or of the pipe through which it is conveyed, it follows that the same pipe will be susceptible of different velocities, which it will preserve uniform to any distance, according as it has different degrees of inclinations; and each inclination of a pipe, of given diameter, has a certain velocity peculiar to itself, which will be maintained uniform to any distance whatever. But this velocity changes continually, according to a certain function of its inclination for all degrees between its vertical and horizontal positions."

It is obvious that, considering the number of causes that may give rise to inequalities in the motion of water, whether in pipes or canals, it would have been vain to attempt the determination of the function above-mentioned from theory only: the results of the several experiments were, therefore, examined with the most scrupulous attention, and penetrating ingenuity, and from which at length the author derived the following theorems, viz.

Let V be the velocity of the stream, measured by the inches it moves over in a second; R a constant quantity, viz. the quotient obtained by dividing the area of the transverse section of the stream, expressed in square inches, by the boundary or periphery of that section, minus the breadth of the stream, expressed also in inches, viz.  $R = \frac{w b}{b + 2 h}$ ; where  $w$  is the mean width of the section,  $h$  the mean height or depth, and  $b$  the breadth at bottom.

The line R is called by du Buat the *radius*, and by Dr. Robison the *hydraulic mean depth*.

Lastly, let S be the denominator of a fraction, which expresses the slope, the numerator being unity; that is, let it be the quotient obtained by dividing the length of the stream, supposing it extended in a straight line, by the difference of level of its two extremities; or, which is nearly the same, let it be the co-tangent of the inclination or slope.

Then the general formula expressing the velocity V, supposing uniform, is,

$$V = \frac{307 \sqrt{R - \frac{1}{10}}}{\sqrt{S - \frac{1}{2} h. \log. (S + \frac{1}{10})}} - \frac{1}{10} \sqrt{R - \frac{1}{10}}, \text{ or}$$

$$V = \sqrt{R - \frac{1}{10}} \times \left( \frac{307}{\sqrt{S - \frac{1}{2} h. \log. (S + \frac{1}{10})}} - \frac{1}{10} \right).$$

But when R and S are both very great, then,

$$V = \sqrt{R} \left( \frac{307}{\sqrt{S - \frac{1}{2} h. \log. S}} - \frac{1}{10} \right) \text{ nearly.}$$

Hence it follows, that the slope remaining the same, the velocities are as R, or as the area of the section divided by its perimeter, minus the breadth of the river at the surface, very nearly; for they are as  $\sqrt{R - \frac{1}{10}}$ ; and when the river is large, the  $\sqrt{R}$  may be used without any sensible error.

Again, if R is so small, that  $\sqrt{R - \frac{1}{10}} = 0$ , or  $R = \frac{1}{10}$ , the velocity will be nothing, which agrees very well with experiments; for in a cylindric tube  $R = \frac{1}{2}$  the radius: the radius, therefore, is only two-tenths, so that the tube is nearly capillary, and the fluid will not flow through it.

The velocity may also become nothing, by the slope becoming so small, that

$$\frac{307}{\sqrt{S - \frac{1}{2}h \cdot \log. (S + \frac{1}{2}h)}} - \tau^2 = 0;$$

but if  $\frac{1}{S}$  is less than  $\frac{1}{\tau^2}$ , or than  $\frac{1}{\tau^2}$  of an inch to an English mile, the water will have sensible motion.

In a river, the greatest velocity is at the surface, and in the middle of the stream; from which it diminishes towards the bottom, and the sides, where it is the least. It has been found, from experiment, that if, from the square root of the velocity in the middle of the stream, expressed in inches per second, unity be subtracted, the square of the remainder is the velocity of the bottom.

Hence, if  $v$  be the velocity in the middle of the stream, the velocity of the bottom will be expressed by  $(\sqrt{v} - 1)^2 = v - 2\sqrt{v} + 1$ .

The mean velocity, or that with which, were the whole stream to move, the discharge would be the same as the real discharge, is equal to half the sum of the greatest and least velocities, as computed in the last proposition. Therefore, if  $v$  represents the greatest velocity, then will the mean velocity =  $v - \sqrt{v} + \frac{1}{2}$ .

Suppose that a river, having a rectangular bed, is increased by the junction of another river equal to itself, the declivity remaining the same; required the increase of depth and velocity. Let the breadth of the river =  $b$ , the depth before the junction  $d$ , and after it  $x$ ; and, in like manner,  $v$

and  $v'$  the mean velocities before and after; then  $\frac{bd}{b+2d} = R$  before, and  $\frac{bx}{b+2x} = R'$  after, so  $v = \frac{307\sqrt{R}}{\sqrt{S}}$ ,

supposing the breadth of the river to be such, that we may reject the small quantity subtracted from  $R$ ; and, in like manner,  $v' = \frac{307\sqrt{R'}}{\sqrt{S}}$ ; then substituting for  $R$  and  $R'$ ,

$$\text{we have } v = \frac{307}{\sqrt{S}} \times \sqrt{\frac{bd}{2d+b}}, \text{ and}$$

$$v' = \frac{307}{\sqrt{S}} \times \sqrt{\frac{bx}{b+2x}}.$$

Multiplying these into the area of the sections  $bd$ ,  $bx$ , we have the discharges, viz.

$$bdv = \frac{307}{\sqrt{S}} \times \frac{bd\sqrt{bd}}{\sqrt{(b+2d)}}, \text{ and}$$

$$bxv' = \frac{307}{\sqrt{S}} \times \frac{bx\sqrt{bx}}{\sqrt{(b+2x)}}.$$

And since the last of these is double the former, we obtain

$$\frac{bx\sqrt{bx}}{\sqrt{(b+2x)}} = \frac{2bd\sqrt{bd}}{\sqrt{(b+2d)}}, \text{ or } \frac{x^3}{b+2x} = \frac{4d^3}{b+2d}$$

$$\text{whence } x^3 - \left(\frac{8d^3}{b+2d}\right)x = \frac{4bd^3}{b+2d},$$

a cubic equation solvable by the formula of Cardan. As an example, let  $b = 10$  feet,  $d = 1$ . then  $x^3 - \frac{8}{12}x = \frac{4}{12}$ , where  $x = 1.4882$ , which is the depth of the increased river. Hence we have  $1.4882 \times v' = 2v$ , and  $1.4882 : 2 :: v : v'$ ; or  $v$  is to  $v'$  as 37 to 50 nearly.

When the water in a river receives a permanent increase,

the depth and the velocity, as in the example above, are the first that are augmented. The increase of the velocity increases the action on the sides and bottom, in consequence of which the width is augmented, and sometimes also, but more rarely, the depth. The velocity is thus diminished, till the tenacity of the soil, or the hardness of the rock, affords a sufficient resistance to the force of the water; the bed of the river then changes only by insensible degrees, and, in the ordinary language of hydraulics, is said to be permanent, though, in strictness, this epithet is not applicable to the course of any river. For more on this subject, see Du Buat, "Principes d'Hydrauliques," in two vols. 8vo. Paris, 1806; Boffut's "Hydrodynamiques;" the article *River* in the "Encyclopedia Britannica;" and Playfair's "Outlines of Natural Philosophy."

The best and most simple method of measuring the velocity of the current of a river or canal, is the following. Take a cylindrical piece of dry, light wood, and of a length something less than the depth of the water in the river: round one end of it, let there be suspended as many small weights as may be necessary to keep up the cylinder in a perpendicular situation in the water, and in such a manner that the other end of it may just appear above the surface of the water. Fix to the centre of that end which appears above water, a small and straight rod, precisely in the direction of the cylinder's axis; to the end, that when the instrument is suspended in the water, the deviations of the rod from a perpendicularity to the surface of it, may indicate which end of the cylinder advances the fastest, by which may be discovered the different velocities of the water at different depths; for if the rod inclines forwards, according to the direction of the current, it is a proof that the surface of the water has the greatest velocity; but if it inclines back, it shews that the swiftest current is at the bottom; if it remains perpendicular, it is a sign that the velocities at the surface and bottom are equal.

This instrument being placed in the current of a river or canal, receives all the percussions of the water throughout the whole depth, and will have an equal velocity with that of the whole current from the surface to the bottom at the place where it is put in, and by that means may be found, both with ease and exactness, the mean velocity of that part of the river for any determinate distance and time.

But to obtain the mean velocity of the whole section of the river, the instrument must be put successively both in the middle and towards the sides, because the velocities at those places are often very different from each other. Having by this means found the difference of time required for the currents to run over an equal space; or, the different distances run over in equal times, the mean proportional of all these trials, which is found by dividing the common sum of them all by the number of trials, will be the mean velocity of the river or canal.

If it be required to find the velocity of the current only at the surface, or at the middle, or at the bottom, a sphere of wood, of such a weight as will remain suspended in equilibrium with the water, at the surface or depth which we want to measure, will be better for the purpose than a cylinder, because it is only affected by the water of that sole part of the current where it remains suspended.

It is very easy to guide both the cylinder and the globe in that part which we want to measure, by means of two threads of small cords, which two persons must hold and direct, one on each side the river; taking care at the same time neither to retard nor accelerate the motion of the instrument.

Having

Having the mean or medium velocity of a river, if we multiply this medium, the breadth, depth, and space run over in a certain time, the product will give the quantity of water that flows down in that time. Dr. Halley, in order to estimate the quantity of water that flows into the Mediterranean sea by means of rivers, makes a comparison of the great rivers of Italy, &c. with that of the Thames. (Philos. Transact. Abridg. vol. ii. page 110.) He assumes the breadth of the Thames at Kingston bridge to be 100 yards, its depth three yards, and velocity two miles per hour. He professedly overrates the dimensions, in order to allow more than a sufficiency for the streams received below Kingston. This assumption gives the area of a transverse section of the river = 300 square yards, and the quantity of water flowing down = 20,300,000 tons in a day. This must be overrated by at least, it is supposed, one-third. If the breadth be assumed 100 yards, the depth three, and velocity two miles per hour, it will then give two-thirds of the result above-mentioned; or it will amount to the same thing if we take one-eighth part from all the three data assumed by Dr. Halley, the result being two-thirds of that above; amounting in the year to 166,624,128,000 cubic feet, which is a little more than one-twenty-fifth part of all the rain and dew in England and Wales in a year, as above deduced. Mr. Dalton has estimated "that the water of the Thames is drawn from an extent of country of about 600 square miles, or one-eighth of the area of the whole, nearly. The Severn, including the Wye, spreads over an equal or greater extent of country; and that collection of rivers which constitutes the Humber is superior to either of the other two in this respect. As far as my own observation goes, the Severn and Wye must disembody as much or more water than the Thames; the Humber I have not seen collectedly, but have noticed most of the branches constituting it, and should apprehend it cannot be inferior to the Thames: all other circumstances being the same, the quantity of water carried down by any river should be as the area of the ground from which the water is derived, and on this account the Humber ought to exceed the Thames.

"The Severn, which is partly derived from the mountainous country of Wales, is certainly the most rapid of the three rivers, and probably carries down the most water; as the Thames, however, is generally considered to take the lead, we will suppose, upon the whole, that these three rivers are equal in this respect.

"The counties of Kent, Suffex, Hampshire, Dorsetshire, Devonshire, Cornwall, and Somersetshire, from the Medway to the Avon inclusively, in an extent of 11,000 square miles, do not present us with many large rivers. From their number and magnitude, we cannot form a high estimate of their produce. The quantity of rain for those counties is indeed near the average for the kingdom, as far as the preceding observations determine; but the milder temperature of their winters and greater heat of their springs and summers, will cause a greater evaporation than in some other parts: it is probable the rivers in these counties may amount, when taken together, to  $1\frac{1}{2}$  times the magnitude of the Thames. The rivers that disembody their waters on the coast of Lincolnshire, Norfolk, Suffolk, and Essex, from the Humber to the Thames, though drawn from a country of 7000 square miles, manifestly fall far short of the Thames. The two places in this district, for which we have accounts of the rain, Norwich and Upminster, give a mean of only  $22\frac{1}{2}$  inches annually. This, with the flatness of the country, which prevents the water from running off in some degree, makes the rivers much

less than what might otherwise be expected from the extent of ground. There are but three or four of any consequence. Probably all the rivers may amount to half the size of the Thames. There remains above 6000 square miles in Wales, from the Wye to the Dee, inclusive of the last, and the northern counties of Lancaster, Westmoreland, Cumberland, Northumberland, and Durham, with part of Cheshire, and a small part of Yorkshire, from the Mersey round by the Tweed to the Tees, amounting to 7000 or 8000 square miles, to be estimated.

"These two divisions, though not larger than some others, abound in rivers, many of which are considerable in magnitude and of great rapidity. The rains at an average, it is probable, are double what they are in the S.E. counties of the kingdom. The rivers in these two districts cannot fairly be estimated, I think, at less than four times the Thames. It appears, then, that by this estimation, the water carried off by all the rivers in England and Wales, may amount to nine times that carried off by the Thames = 13 inches of rain. There remains still sixteen times the water of the Thames, or 23 inches of rain to account for, before we have disposed of all the rain and dew."

This ingenious philosopher concludes, from a detail of facts and reasoning, that "the rain and dew of this country are equivalent to the quantity of water carried off by evaporation and by the rivers. And as nature acts upon general laws, we ought to infer, that it must be the case in every other country, till the contrary is proved.

"This conclusion being admitted, we are enabled to deduce a general theorem for the quantity of water carried down into the sea by any river in any country (on the supposition that all rivers are ramified alike) provided we have certain data; these data are the length of the river, and the excess of the rain above the evaporation in the country from which the water of the river is drawn; also, it should be known by observation, how much water some one given river carries down.

"For, from the principles of geometry, the area of country from which any river is supplied, will be as the square of the length of the river; and the quantity of water carried off, will be in the compound ratio of the area of the country, and the excess of the rain and dew above the evaporation.

"Thus, let L = the length of any river, E = the excess of rain and dew above the evaporation, and Q = the quantity of water disembodyed in any given time by that river; l = the length of any other river, e = the excess, &c. and

$q =$  the quantity of water; then we shall have  $q = \frac{Q l e}{L E}$ .

"E. gr. Suppose the length of the Thames = 200 miles, and the excess = 5 inches, estimating the rain and dew at 30 inches, and evaporation at 25; and suppose the river Kent, in Westmorland, to be 20 miles in length, and the excess 35 inches, the rain and dew being supposed 65, and evaporation 30 inches. Then,

$$\frac{20^2 \times 35 \times Q}{200^2 \times 5} = \frac{7Q}{100} = q,$$

or  $Q = 14\frac{2}{7} q$ ; which result, I believe, will be found to accord nearly with the measurement of the two rivers on the principle before-mentioned." Manchester Memoirs, vol. v. pt. 2.

RIVER, with regard to *Agriculture*, may be converted, in many situations, to various useful purposes, such as those of improving the meadow and other grass-lands which lie below the sources of them, by having their waters in particular seasons turned over them. By proper attention in these

these respects, vast benefits might, in a variety of cases, where it has never been even so much as suspected, be derived, and thereby immense savings in manure be made for the amelioration of the less favourably situated lands. But besides this vast source of advantage, rivers may often be converted, with little trouble or expence, to other useful purposes, such as the supplying of live-stock with water, the turning of different kinds of farming machinery, the conveying of cattle food, and manures of various descriptions, as well as different sorts of farm produce, and a great number of other uses, which can only be discovered by the particular circumstances of them, and those of their situations. But though in these views they may be justly considered as of much advantage, in others they are often dangerous, troublesome, and highly detrimental to the farmer, as where they are much accustomed to overflow their banks, injure the crops, sweep away the live-stock, and carry down much of the lands on their borders. Where they are apt to prove hurtful by thus overflowing their banks, the best modes of confining them in particular cases have been pointed out in speaking of the nature of embankments and haugh-land. See **EMBANKMENT**, and **HAUGH-Land**.

There are, however, other cases that deserve to be considered in this place, such as the directing and altering the courses of torrents coming from mountains, changing the courses of rivers, securing the banks of rivers in vallies, and straightening the narrow, crooked windings of small rivers in the same situations, and other hollow parts of lands. By the first of which much advantage may, in different circumstances, be procured, and great security be attained for the valuable lands below. By the second, extensive tracts of the most valuable kinds of land may be obtained, while the whole is rendered more safe and proper for the purposes of pasturage or those of tillage. By the third, much useful land may be secured, as well as much mischief from the high floods be guarded against. And as by the last much ground is often lost, or rendered of but trifling value to the farmer, by proper means these inconveniencies may be obviated, and the land rendered of much greater utility. Besides these, the methods of securing the banks, in other instances where they are liable to be carried away by large floods, may also prove a vast benefit and improvement.

In the former of these cases, the remedies are, in general, those of rendering their courses more *free, open, straight, and regular*, by which they must obviously suffer less obstruction, and of course be less apt to overflow their banks, and prove injurious to the grounds below, or on the sides of them. It is, however, remarked, that this is a sort of work that ought to be maturely considered in all cases before it is attempted; but that in such upland situations the business may often be performed with facility by small cuts made along the flat bases of such elevations, while it is very different in those of frightening vale rivers, as much larger openings are requisite. Besides, shallows for piers and stops are mostly found there, while in these cases they are in general wholly wanting. But in all cases, and in every point of view, the business is evidently of the greatest interest to the proprietors of land, as the destruction produced in this way is not only often committed on the most valuable sorts of land, but is frequently the cause of disputes between the neighbouring proprietors; this sort of work has, however, been little attended to, and is in common very imperfectly understood. In many instances a great deal may be effected by proper accommodation between the different proprietors, whose interests are affected.

But in undertaking works of this nature, there are different circumstances that require to be particularly con-

sidered. The peculiar site or place of improvement should, Mr. Marshall says, be well studied, in order to fix upon the best method of executing the work. And when this has been done, accurate plans and estimates of the expence that may be incurred, as well as of the gross profits that may result from it, be made out with care. And it is advised that, where the business is extensive, and the person who has the management not perfectly acquainted with the nature of it, to contract with proper experienced labourers, or a responsible undertaker, for the execution of the whole, binding the party who is to perform the work to uphold it for a certain number of years after it is finished. It is remarked, that for want of these precautions, sums of money are annually expended, and in great part thrown away, so as to become, in some instances, a heavy tax upon estates, and a serious devaluation of timber. It does not follow, it is contended, that, because a few square yards of land are annually carried away, an expensive work should be erected, and upheld at ten times the value of the ground it will protect; nor that, because one side of a river is slightly injured, an over-sized work should be raised to the greater injury of the opposite banks. It will be found, it is observed, that in ordinary cases, opposite proprietors have one and the same interest; and that small injuries may generally be remedied by simple means, and at a small cost. What the writer is solicitous to inculcate is, that the remedy ought to be proportionate to the disease; and that it should be applied in such a manner as not to injure another: consequently, that it behoves a proprietor to see that no one about him has an interest in erecting expensive and abortive works, or any prospect of advantage from the annoyance of his neighbour in any respect from such works. It is added, that every person has an undoubted right to defend his property. It is often his duty, as well as his interest, to do it. And that there are cases on which even large sums of money may be prudently laid out, and ought to be expended in order to accomplish the work; as by neglect great injury may be sustained, which at first might have been remedied at a very trifling cost.

Rivers, wherever they are properly situated, should always be converted to the use of watering the grass lands which lie below their levels. See **WATERING of Land**.

**RIVER-Banks**, *Securing of*, the means of guarding and protecting them from the encroachment and injury of the streams when in flood or otherwise. It is a work of much difficulty and labour in many cases, and that requires the careful management of an experienced director. It is indeed remarked by the author of the *Treatise on Landed Property*, in speaking of the nature of this business, that supposing the uniform, and evenly-poised, current of a reach or straight part of a river to be disturbed by the body of a large root of a tree, or any other matter, brought down and lodged by a flood, on this side, which, in brooks and narrow rivers, is an ordinary cause of mischief, it is found that through this apparently trifling incident the current may be said to lose its balance. For, when the flood falls to the level of the obstruction, the water becomes confined in that part; its height, above the obstruction, is consequently increased; and its current opposite and below it not only accelerated, but gently turned from its direct course toward the opposite bank of its natural channel; which, if it be of an earthy crumbling nature, becomes undermined: the land, or upper part of the bank, consequently shoots down, and is carried away by succeeding floods. And what tends to increase the evil is, the circumstance of the channel, immediately below the obstruction, becoming occupied, even in minor floods, with comparatively stagnant water. It is in conse-

## RIVER.

quence warped up with the sediment there deposited; and by this means an additional weight of water is thrown against the opposite bank; which, if the growing cause of mischief be not speedily removed, will in a short time be much torn away, and, in a course of years, a bend or bay be formed in the adjoining ground of the proprietor, nearly opposite to the root or other body, with a corresponding bank of sand or gravel, united with and becoming part of the lands on this side. But if the grounds, on this side, are equally vulnerable as those of the opposite neighbour, there is no cause of exultation in the increase of territory. For while the current is leaving the proprietor on this side, perhaps a worthless sand-bank near the obstruction is, by a natural law of river-currents, scooping out a bay below, and giving to his opposite neighbour an increasing territory in that part. And thus a natural loss of valuable land is incurred on each side; and the evil (in this case) continually increasing; until the banks are securely defended, or the current is restrained, and directed into its former channel. The remedies in this case are two; first, to sheath the injured banks of the bays on both sides, with such materials as will resist the circuitous current, and let the river remain in its crooked state; and, secondly, to erect a pier at the higher point of the bend on the opposite side of the river, to parry off the force of the current from the bank of it, and direct it forward; with the twofold intention of preventing further mischief, and of bringing back the course of the river to its former state of straightness, as much as possible.

It is likewise stated, that the operation of guarding the immediate bank of a sharp river-bend against a heavy current, meeting with great resistance, is generally a work of much difficulty and expence, even where materials can be easily procured; while that of diverting the current may frequently be accomplished at a comparatively small cost; and its effect be rendered infinitely more salutary and permanent. As it is evident that, if the accidental obstruction mentioned had been timely removed, no bad effect would have ensued, and the river would have continued its direct course. Or if, through neglect, it had been suffered to remain awhile, until its mischief was discoverable, even then, if it had been moved from its station to the opposite side of the river, and placed in the part affected, this small counterpoise might have recovered the balance of the current, and directed it into its wonted channel. And in almost any case, he thinks, by judiciously placing, in a similar manner, an obstruction proportioned to the magnitude of the power to be counteracted, the like effect may be produced. As, for instance, if, in the case proposed, the pier or river-guide above-mentioned were to be erected by the proprietor on the opposite side of the river, and to be inclined towards the stream, or direct course of the river, in a degree proportioned to the strength of its current (a rapid current requiring less bias than a slow one), and of a size in like proportion, not only the banks of the bay or bend would be defended, in a great degree, from the action of floods, but the sand-bed formed on this side would be worn away, and its materials deposited in the bay on the other side; which also being rendered stagnant, comparatively, with the current of the river, would receive the deposits of foul waters in times of floods; and thus, in a twofold manner, be refilled and brought back toward its former state. And, further, that if, when the gravel bank on this side is sufficiently removed, the proprietor on the same side were to erect a similar pier at the higher point of the bend on the same side, the sand or gravel bank on the other side would, in like manner, be worn away, the bay on this side be returned to its original

proprietor, and the straight course of the river be regained; then the piers ought to be removed, whether they belong to one or two proprietors; the latter having generally a mutual interest in directing the river, which separates their properties, into a straight course, as much as can be done.

It is stated, that in the construction of a river-guide for this purpose, there are certain principles and particulars of practice to be observed. It is suggested that its position should be such as to produce the required effect, with the least degree of resistance. For the current of a river, as the waves of the sea, ought to be subdued by stratagem rather than by force. Resistance serves but to increase their fury. A wave falling on a flat shore, seems to die without a struggle; while one that is stemmed by an abrupt rock strikes with tenfold force. And, in like manner, a rapid river will glide smoothly along the side of an even bank, though it may somewhat deviate from the direct course; without perceptibly disturbing the current, or injuring the bank that directs it, even though merely of turf. But when a strong current meets with an abrupt projection, or a sharp bend in its channel, its fury is roused. There, rock is sometimes barely sufficient to resist its force. On these principles it is, therefore, conceived, that in erecting a pier with this intention, it ought to be made to unite evenly with the natural bank of the river above it, and, where the required deviation from a straight line is considerable, the face of the pier ought to pass off from the natural bank with a smooth hollow curve, that the force of the current may not be checked. But its outer or lower end should be straight, or nearly so, and be directed, as a piece of ordnance, to the object it is intended to destroy—to the obstruction it is intended to remove; and it may be observed, that the nearer it approaches this, the greater will be the action of the current upon it, in times of flood; and the less liable the stream will be, at low water, to turn back into its former channel. For, in cases of this kind, the current of a flood, and that of low water, (if not better directed,) take different courses, according to their heights and strengths. The one rushes forward in the direction desired, the other, unable to surmount the obstruction, and flagging for want of strength at the point of the pier, doubles it; and falls back into the bay with an accelerated current; directed, perhaps, straight to the injured bank; and may thus increase, perhaps, rather than prevent, the injury. But in order to remedy this evil effect, and to direct the current, at every height, into the same channel, it will generally be found right, where it can be done, and at a reasonable expence, to cut a channel through the obstructing bank, large enough to admit the stream at low water; depositing the materials which are raised in doing it at the point of the pier, and against the foot of the injured bank: by these means not only preventing further injury to the lands on the opposite side, but greatly assisting the action of the flood-currents to force their way through the channel, and enlarge it; and, in a short time, lay open the required course. For although, by this procedure, the bay on that side might not be so readily and completely filled up, as it would by fullering the current to throw back the obstruction, by degrees, in the manner above represented; yet the advantage of putting an immediate stop to the ravages both of floods and of low water, might counterbalance that defect; even though the pier were thereby rendered necessary to be kept up in perpetuity. The expence of the cut may generally be saved in the required *length* of the pier; whose use, in this case, is, merely that of giving an easy bend to the current; so as to enable it to find its own way

to

## RIVER.

to the channel prepared for it. And the *strength* required, depends upon the weight of water, the force of the current, and the angle of deviation from the given direction of the current immediately above. If the required direction of the pier be nearly the same as that of the current above it, it has, it is contended, little more than the weight of water to sustain. Whereas a jutment run out, abruptly, into the natural course of the current (as is commonly seen), has not only the weight, but the force, of the water to withstand; and requires threefold, or tenfold, the strength of structure that is necessary in the other case. Another circumstance to be particularly regarded in this sort of business, is the height of the conductor. Where it is run out from the bank into the channel of the river, in rather a straight manner, and if it be not raised high enough to prevent the waters of floods from making their way over it, its foundation may be endangered; especially in a place where the general fall of the river is considerable. For an overfall of water, unless it have a firm basis to act upon, naturally scoops out a pit at the foot of the fall; and undermines the precipice it tumbles over; seldom failing to let down such as are constructed by art.

With respect to the means of obviating this effect, they are three, one of which is to raise the pier high enough to prevent the overfall; an expedient, however, which cannot always be practised with propriety. Another is to form the lower side, or back part of the pier, with a shelving or flatly inclining surface, to break or elude the fall. And the other, to prepare a convex floor behind the pier, for the waters to fall upon. This last has been found successful in the writer's own practice. There is likewise another point that demands particular care in the operator, which is that of securing the point or outer end of the pier, not only at the foundation, but in the superstructure. For although the main current cannot, if the pier is judiciously placed, exercise its strength upon this part; yet, by reason of the weight of water there losing its support, and part of it, consequently, rushing precipitately into the unguarded bay, the lower end of the pier is peculiarly exposed to danger in that way. It is supposed scarcely necessary to add, that the upper end of the pier ought to be deeply inserted in the firm bank of the river, to prevent the current from insinuating itself behind the facing, or that the face of the pier should be carried up with a sufficient batter, to give it firmness; or that the foundation ought to be securely laid, and to be kept sedulously guarded in front, to prevent its being undermined by the current. Rough stones, thrown down loose, and with a flat shelving surface, against the foot of the pier, are, in most cases, the best guard, let its materials be of what sort they may.

It is advised, that the materials for this use should be suited to its occasion, where a choice is to be had. If a low defence, only, is wanted, in a district where large rough stones are plentiful, a long pile of loose stones, laid flatly sloping against the bank of the river, or a flat ridge run out from it, may form a cheap and durable barrier. For should they be disturbed by an extraordinary flood, they may be readily replaced when the water subsides. Where a tall pier is required to direct a large and rapid river, in a place where stones and strong cement may be procured at a moderate expence, masonry may be eligible. But in exposed situations, at least, it ought to be guarded with timber, especially at the top and the outer end (as the piers of sea-ports, and the quays of navigable rivers, are guarded), to defend those parts from injury by ice, timber, or other large floating bodies, driven

against them in times of flood. And that where masonry cannot be used, but at a great expence, a *caisson*, formed with posts and planks of adequate dimensions, and filled with pebbles, gravel, or other indissoluble materials, to give stability to the fabric, may be found to last as long as its services may be wanted; and, in some cases, may be removed while its materials may yet be valuable.

But this, though the prevalent method, is merely palliative, and demands frequent repairs: it does not cure the evil, or bring back the lost property to the owner who has a right to it. Nor is it in such a case beneficial to a rival owner, for the current, as has been shewn, sweeping circuitously along the banks of the bay, is thereby led to direct its force against the lands of the proprietor on this side, who cannot, under these circumstances, defend them by the above means; but who must either secure them by a lengthened land-guard, or leave them at the mercy of a sweeping current. It is therefore concluded, that, in a case of this kind, it is evidently the best interest of an opposite proprietor to suffer his sand-bank, or gravel-bed, to be cut through, in the manner suggested, and that he ought to assist in the operation; as he will thereby not only get rid of the circuitous current, but, by the action of the floods, in the straightened course, his bay will scarcely fail to be filled up with the scattered materials that may be removed.

There is another case in which this sort of pier or river-guide may be made use of with success; which is that where a stream of the above description falls down a crooked valley, and necessarily takes, at certain points, a winding course.

In this case, where the quantity of water is considerable, its fall rapid, and especially where it is conducted to the bend on the farther side down a straight, unobstructed reach, scarcely any thing but natural rock can resist its force in that part. In such situations it is not unusual to see earth-banks scooped out and undermined, until a perpendicular cliff of twenty or thirty feet high be formed. But if a pier be erected at the upper part of the bend, with an easy curve from the natural course above, so as to bend the current without breaking it, and direct it into its natural channel, in the valley below, it will have nothing to contend with but the loose gravel beds on the different sides, which, if cut through, as in the former case, will presently be torn away, and a principal part of their materials be deposited in the bays on each side, but especially in the latter, or that on this side: so that in this, as well as in that case, both sides of the river may be benefited by the alteration which is thus produced. It is however stated, that there are cases in which nothing but an immediate sheath, or *land-guard* applied to the injured part, can be properly used to prevent further depredations. As, first, where the river is confined in the part where it is required to be bent, by rocks or otherwise, to an unaltered channel; as it frequently is in sub-alpine situations. And, secondly, where a deep pool occurs in that part at low water, so as to render it difficult to get a proper foundation for a pier. It is observed that, in the former situation, stones are generally plentiful; and they require to be applied according to the circumstances of the particular case. Where the foot of the injured bank is covered with a pool at low water, it is advised to shelve off the brink of the bank, and shoot down loose stones from the top of it; suffering them to form their own slope in the action of falling, and by the operation of succeeding floods; continuing to pour them down until the bank be secured, at least from minor floods; and then to

slope

slope back the upper part, to give freedom to floods of higher magnitude. But that where it is in the face of an impetuous torrent, and at some little distance from it, a gravel bed is thrown up, so as to lie dry during low water; yet where lands, behind, are liable to the ravages of floods, as is often the case, and especially where stones are not plentiful, a more frugal arrangement of them may be made, by using them merely to ease the exposed bank, so as to prevent the currents of floods from laying easy hold of it, and tearing away the land. However, in this case much depends on the plan and construction of a safeguard of this kind. It ought to be every way convex; so that the strength of the current and the weight of the water may act upon it, as superincumbent pressure acts upon an arch. It should bulge out, horizontally, towards the known current of floods, (without regard to the course of the stream at low water,) and the face of the wall ought to take the barrel form. A cross section of the stone-work should resemble a semi-arch, or, in dangerous situations, it ought, it is conceived, to fall back flatter than the quadrant pitch. For, in general, the flatter it is made to lie, the more secure it will become; but the steeper it is carried up, the fewer materials, and the less labour, it will require. And in forming a work of this nature, the foundation should be laid pretty deep, to guard against any accidental scoopings of the floods. The wall ought to be carried up dry, or without mortar, the stones being laid with their ends outwards, their inner ends pointing to the same centre, like those of an arch, and to be backed with gravel or earth, rammed in firmly behind as the facing is carried up. The *coping*, or uppermost course of the stones, should be securely bound with thick tough fods (eight or ten inches deep), whose surfaces, when beaten down, ought to lie even with that of the stone-work; and similar fods require to be laid, with a gentle rising slope, until they unite smoothly with the natural turf of the land to be defended: so that the waters of floods, when they rise above the stone-work, may have no abruptness to lay hold of, but may pass away smoothly over the surface of the land, as they commonly do over smooth greenward, without injury. And, lastly, that the stones are to be beaten forcibly into the bank with a rammer, a mallet, or a small battering-ram adapted to the purpose; thus rendering the whole compact and firm to resist the current. Where vacancies or fissures still appear, long splinters of stone are to be driven in, as wedges, to increase the firmness, and prevent the current from tearing out an unguarded stone. It follows, in course, that the largest and longest of the stones ought to be used where the greatest resistance is known to be necessary, in order that the greater security may be attained. It is remarked that this sort of defence, like that of every other species of the river kind, requires to be attended to from time to time, especially after great floods. If the foundation be laid bare, it requires to be recovered with rough gravel, or with stones thrown loosely against it. If any of the facing stones be displaced, or loosened, they are to be replaced with others, or to be wedged in afresh. Or if the turf which binds them at the top be disturbed, the torn part should be cut out square, and be firmly and completely filled up with fresh curves. It is added, that this method of defence against rapid rivers originated in the ingenious writer's own experience and practice; and that, when compared with a wooden guard, it is cheap, fighty, and durable.

It is noticed further, that there are cases of other kinds, as those which are found in the skirts or margins in the valleys of mountainous situations, through the plains of which the rivers are found winding with devious courses, or tracing

the margins at the feet of the containing heights. In some instances, they are confined in deep-funk channels, whose banks they seldom overflow; but, much oftener, their channels are funk a few feet only beneath the general surfaces of the lands they pass through. Hence, in high floods, they may be said to be let loose over the plains, to ravage them at pleasure. Their immediate banks, however, are generally the victims of their rage. These they tear away, and ransack off their better parts; substituting beds of stones and gravel, or perhaps their own channels, in the stead of what were, a few hours before, valuable lands. And that there are instances of mountain torrents, on rushing out of their confined channels into flat vale districts, ravaging many acres during a single flood. And to confine or direct these, is, it is observed, often a business of vast difficulty and trouble.

In these cases, the best endeavour of the artist is generally, according to Mr. Marshall, to give the river a direct or straight-forward course, on its quitting its restraining channel, at its first entrance into the area of the plain; and, if no obstruction lies in the way, to continue the straight line to another retaining channel, at the lower end of the area to be improved. But that where the area is winding, or some obstruction rises within it, so that a straight line cannot be drawn from the entrance to the outfall, an insuperable difficulty may seem to frustrate this mode of improvement; as the current requires to be bent, not only after it has entered the plain, but after it has acquired an increase of velocity by moving in a straight course. By actual practice and experience, he was led by another circumstance belonging to it, to what may, perhaps, be considered as a principle, in conducting improvements of this nature. A straight cut into the middle was desirable: but the point of rising-ground rendered it impracticable. Near the centre of the flat, a large insulated fragment or islet of rock rose ten or more feet above the level of the area; and at the lower end of it, near the natural outlet of the river, a bank of rock had formerly been washed by it. It was easy to perceive that the insulated rock, which commanded both the extreme points of the area, might be employed in uniting them; and that, by the use of that rock the work might be rendered complete. For, by opening a straight course to the rock in the middle, and another from thence to the bank of rock at the outlet, the current would be directed, in another straight line, to the outlet, and the site of improvement be entirely freed from its injurious effects. He remarks, that it is in few instances that prominent rocks, firm enough to resist the current of an impetuous river, rise in the areas of river-worn plains. But that, on the sides of mountain vallies, rocks are common; and may, doubtless, in many instances, be employed to throw the river from side to side of a crooked valley, in straight reaches; as rays of light may be reflected in continuation by well-placed mirrors. Even where natural rock is not present, either in the area, or on the sides of such a plain, or flat-based valley, rising grounds may frequently be found within the former, and are never wanting on the sides of the latter. And, against these, artificial buttments, of sufficient strength, may not unfrequently be formed in alpine situations, where stones are generally plentiful, without any very great expence.

It is observed, in respect to the *altering the course* of a river or brook, that the difficulties and expence depend on the particular circumstances belonging to it. In a simple case, in which one straight cut only is required, the principal difficulty, and that which requires the best skill of the artist, lies in directing the current of the first flood out of the old into the new channel. But if a bend of the old channel,

like that just noticed in the above case, can be made use of, this difficulty may be said to vanish. The mouth of the new cut receives the current with a straight course; consequently, if it be made of sufficient capacity, the river in a flood can have no propensity left towards its old channel; and the loose materials which rise in forming the mouth of the new cut will generally be sufficient to turn the stream at low water into it. But if a suitable bend cannot be approached by the new cut, a directing pier, like that in the above case, will be required to bend the flood-current, and give it a straight-forward course into the new channel; a water-tight dam being formed between the point of the pier and the firm bank of the new channel, to prevent the water from regaining its former course or direction.

But in regard to the cutting of the new channel, it is merely a work of manual labour; being attended with no other difficulty than what may arise from the expence; which will depend on the size of the river, the nature of the ground to be cut through, and the value of labour in the given district. It is mostly to be ascertained with sufficient accuracy, by previous calculations. And it is added that the required *size* of the *new cut* is small compared with that of the old channel. For the currents of floods, by carrying off the earthy particles with which they come in contact, will soon enlarge it. It is nevertheless right to give ample room in the new channel, lest the first flood should prove high, and, by bursting its bounds, force its way back to its former course. Therefore, in order to give the required capacity to the new channel, and to allow for its widening, the materials which arise in making it ought to be formed into regular embankments on either side of it, and at sufficient distances from its brink, to obtain the above purposes; and, moreover, to protect the adjacent lands from the injurious effects of unrestrained floods. And it is further suggested, that a new river course requires to be carefully attended to, during a few years after it is opened, to see that its channel preserves its straightness, and that no breaches are made or threatened in its banks. And that, considering the uncertainty of extraordinary floods, it cannot be said to be out of danger in less than three years. Of course, in contracts for these works, in these cases they should be upheld for that time, and then delivered up in the state fixed upon in the agreement.

There are still other cases of rivers in lowland situations, where the currents of them are generally sluggish, and their beds deep sunk and narrow, with few shoals or firm bases on which to found piers or bulwarks, and few stones with which to raise them; and even if erected, the sluggishness of the current may render them ineffective. In these cases the banks are steep, and often of the tenderest earths, liable to the slightest attacks of agitated water, especially near their feet, where they are naked of vegetable covering. Hence, it is from the frettings of the minor floods, or the waves of the dead water which occupies the channel of a river of this description, that its banks are worn away; especially at a bend which faces a length of reach, in which the waves have room to rise. These fretting against the foot of the bank undermine it. The face of the bank, in consequence, floats down; and the prostrated soil is dispersed by the next flood. It is consequently observed, that the most essential work, in a case of this kind, is to guard the foot of the bank up to the level, and somewhat above the level of low water. And, this done, to slope back, smoothly, the upper part of the bank, to enable it the better to support a vegetable covering, and withstand the attacks of higher floods, as well as to render it less dangerous

to pasturing flock, and enlarge their field of pasturage. And that when, with the increase of capacity, the channel is still unable to contain the waters of great floods, lines of embankment may be raised on either side of it, with the foil removed in forming the slopes; and thus restrain them within due bounds. Likewise in particular parts, as at sharp bends, when ordinary sward, or pasturable turf, is not able to prevent the current, in this trying situation, from breaking up the foil, it should be bound more securely together by stronger rooted plants; of which the osier is said to be profitable to be planted upon the top of a rich river-bank; but it is altogether unfit to occupy its face for the purpose here required, though commonly used; as it tends to counteract one of the intentions proposed in sloping back the face of the bank; by filling up the space thereby prepared for the waters of high floods to spread in; and thus increases the current at the foot of the bank. A much more eligible and effectual guard presents itself, Mr. Marshall says, in the furze, whose roots not only form a mat of strong fibres in the foil, but bind it down to the substratum in a singular manner. Yet even the furze, if suffered to run up to its greatest height, may frustrate the intention of propagating it. It ought, therefore, to be cut down from time to time as fuel; or to be kept close mown, so as to form an invulnerable shield to the face of the slope. But it is observed that if we examine into nature's practice in guarding the foil of river-banks, we shall find it carried on with the best effect by the butter bur (*tussilago perfoliata*).

But in these cases of securing the banks of rivers, Dr. Anderson has long since given more full and ample directions. He remarks, that when a river runs in a bed of rich vegetable mould, the least accident that may chance to direct the stream towards any particular part of the bank, causes it to sweep away large tracts of fine ground, to the very great detriment of the proprietor, as well as the public; as this fine mould is usually carried to the sea, and the materials that the water leaves, to occupy the new bed that it thus forms for itself, is generally of a much worse quality, consisting chiefly of stones, sand, and gravel. And that where the whole force of the current is quite close to the bank, and the materials necessary for fencing it are not to be there found, it may perhaps be impossible, or very difficult, totally to prevent this evil: but, for the most part, it admits of a cure, that can be obtained at a pretty moderate expence. For if you carefully observe the banks of rivers, you will readily remark that these ravages are always most considerable at those places where the banks rise perpendicularly to a pretty considerable height above the ordinary surface of the water, and never at those places where the banks shelve down gradually towards the water's edge: for when the river is swelled to a great height by rains, and runs with a greater force and rapidity than usual, it strikes violently against these perpendicular banks that directly oppose its course; and as they are composed of earth, quite bare and uncovered, they are easily softened by the water, and quickly washed away; so that the upper part of the bank, being thus undermined, falls by its own weight into the river, and is carried off in prodigious quantities. But when the river rises to any considerable height, it generally glides along the surface of those parts of the bank which shelve gradually downwards to the water's edge, which being defended by the matted roots of the grass, with which it is covered, scarcely sustains any damage at all, and is nearly the same after the water has retired within its banks, as before the inundation took place. He thinks that these are facts, which no one, who has bestowed the least attention to this subject, can fail to have observed; and that they

clearly point out, that the first and most necessary step towards a cure is to level down the edge of the bank that is next the water, so as to make it slope gradually down towards the river. And that where the bank is very high, and you have no other particular use for the earth that must be taken from it, the easiest method of disposing of it will be to throw it into the river. But in whatever manner you dispose of the earth, the slope of the bank must be continued until the inner edge of it is as low as the surface of the water, at the driest time of the year, and be made to ascend gradually upward from the water with an easy slope, till it comes to the level of the ground, or at least rises to such a height as the water never exceeds. And the work ought to be performed as early in the summer as possible; and the slope should be either immediately covered with turf, pared from the surface of some field that has a very strong sward upon it, taking care to lay their ends in such a manner as to be in as little danger as possible of being washed away by any accidental flood that might happen, before they are grown together; or, if turf of this kind cannot be had, it should be sown very thick with the seeds of some small mat-rooted grass, that should be kept in readiness for that purpose, such as the creeping meadow-grass. If the stream has not been extremely rapid at the foot of the bank, some of the earth that was thrown into the water will be allowed to subside to the bottom, and will there form a bed of loose soft earth, which will be of very great use afterward in preventing the face of the bank under water from being washed away. But in order to secure this bulwark effectually for the future, the surface of this soft earth ought to be instantly stuck full of the roots of bog-reeds, flags, water-spiderwort, rushes, and other mat-rooted aquatic plants; which, if allowed to remain till they have once struck root, will afterward form a barrier that nothing will ever be able to destroy. It is added, however, that if the stream be too rapid to admit of this, and the bank of soft earth much deeper than the surface of the water, it will be of great use to fill up the breast of the bank with small loose stones, with a little earth intermixed among them, carelessly thrown in till they rise near the surface of the water, which would most effectually secure it against any future encroachments, if the bank is sloped away above. It is further stated, that in case it should so happen that stones cannot be easily got for this purpose, the only recourse is to dig the bank so low, as that at the undermost edge it may be always below the surface of the water, and carry it out in this way for a considerable distance; and then flick the whole surface, that is below the water, full of mat-rooted aquatic plants, throwing it over, if possible, with a thin bed of small gravel or sand, as convenient, which will in a great measure, if not entirely, defend it from future encroachments. And this bank ought to continue to shelve downwards, even where it is below water; and those aquatics that will grow in the greatest depth of water be planted on the innermost bank, and the others behind them. The water-spiderwort will grow in four feet depth of water; and the roots of the common yellow-flowered water iris forms such a strong and compact covering, upon the surface of the soil on which it grows, as would defend that soil from being affected by the water almost as well as if it were a rock. It is likewise an advantage attending this plant, that it grows upon a firm bottom, and chiefly delights in running water. But where the stratum of soft earth is not so deep as to reach to the surface of the water, and lies upon a stratum of rock or hard gravel, there will be no occasion for throwing in stones of any kind. But as it is difficult to unite the vegetable mould to any of these strata,

there will always be some danger of its separating from them, in violent inundations; and if the water once gets an entry, the breach will not fail to grow larger and larger by every inundation. To prevent this inconvenience, it will be necessary, after you have sloped the earth away till you reach the gravel or rock, to cover the place where the edge of the earth joins the inferior stratum with a good many small stones, if they can be found, sowing between them the seeds of any kind of plants that you think are most likely to thrive, which have strong matted roots, with as small and flexible tops as possible. But where the object is of great importance, it will be still more effectually secured, if the face of the rock be dug entirely away for some distance backward, and the place which that rock originally occupied be then filled up with earth, and sloped back in the same manner as if it had been an earthen bank, in which no rock was to be found. In all operations of this sort, great care should be taken that no stones should be mixed with the mould; for every thing that makes an inequality on the surface, or a difference in the firmness of particular parts, is extremely pernicious. It is evident, that from the impossibility of ever making earth adhere firmly to stone of any kind, it must always be an improper practice to face the banks of a river to a certain height with stone, which is capped at top with earth; as it must always be liable to be removed. This method has been since found to answer perfectly in actual trials in such cases.

There is, the same author observes, another mischief produced by the swelling of rivers, from the water overflowing the rich flat ground, that is frequently met with on the sides of them, which sometimes prevents them from being got laboured at the proper season, sometimes sweeps off at once the whole crop, and sometimes destroys it by covering the whole surface with stones and gravel, to the unspeakable detriment of the possessors of such ground. And as these lands, sometimes termed *haughs*, are generally very rich and fertile, and sometimes of great extent, the damage that is done by not getting them properly cultivated is very considerable. In respect to the mode of removing this sort of inconvenience, it is remarked that these haughs are seldom of great extent, excepting on level tracks, where the water runs with no impetuous current; and, therefore, they may in general be preserved by means of a sloping bank, raised all along the side of the river, as far as the haugh extends, which, if formed by the same plan as those described above, will easily confine the water within their boundaries, till it rises so high as to overflow the top of the bank; so that if these are raised to a sufficient height towards the back part, in such a manner as to be capable of containing the whole of the water that at any time flows down the river, the fields on each side will be effectually secured. And that where the surface of the ground in the haugh is at any considerable height above the water in the river, the bank may perhaps be raised to the necessary height, by throwing the earth that is taken from the brink of the river to the other side of the bank, so as to form the new surface of the bank on that direction, instead of the old surface. But if the surface of the ground is level on the opposite side of the river, the earth that is taken from the triangle in the whole will not, in that case, be sufficient to fill up the whole of the other triangle, and raise the bank to a proper height; to make up which deficiency, it will be necessary to dig a ditch at the back of the bank, throwing the earth into the higher part of the bank, and facing up the line with stones or turf, so as to make it become a fence to one side of the field that it preserves from inundations. However, where the surface of the ground is extremely low, so as to be but

little above the level of the water, then, instead of raising the bank on each side to the proper height, it will be more advisable to raise them only to the height of a particular line; as, in that case, it would be very difficult to find as much earth as would form both the banks, although there will be no difficulty in forming the smaller one; and as the areas of the two are equal, these lower banks will contain an equal quantity of water within them, as the higher ones would have done; the greater width between them making up for their want of height. And it is conceived, that in this way it will be in the power of any man so to proportion his banks to the circumstances in which he finds himself placed, as in the easiest manner to accomplish his design: for if he has plenty of materials at hand, he may rear his banks to a greater height, and confine the river to a narrower course; and if he finds a deficiency in that respect, he may make them of a smaller height, and allow the river to spread to a greater breadth. It is added, in concluding this account, that this method has been found to answer very well in actual practice; but that, in some cases, it was found that while the bank was new raised, and before the surface was grown together, some parts of that surface were broke a little, when the water rose to a great height. In this case, the bank consisted entirely of loose sand, which is the worst material it could be formed of; but this was easily repaired, at a very small expence, when the water subsided. If these small breaches, however, had been neglected, there is no doubt but the whole would quickly have been destroyed. It was found that a few small stones, laid upon the surface of the sward, near the edge of the water, proved in this case a very useful addition. In cases where the sward is firm, this caution would have been unnecessary. Whoever attempts this mode of fencing, should take care to provide themselves with a sufficient quantity of the seed of the plant, usually called *sprots* in Scotland, to sow near the edges of the water; for these other kinds of grasses are shelled, and without this precaution, the surface remains bare, and is therefore liable to be washed away with the water, during the time of floods.

There are other cases in which attention is sometimes necessary to rivers, which are in those of the vale kinds, which run in very serpentine or crooked directions. In these cases it is sometimes proper to straighten them, though it is but in few instances, Mr. Marshall thinks, that this can be done with propriety and advantage, in respect to profit. And though the principles and management are the same in the execution, there is much difference from the want of suitable materials, &c.

The instances in which the courses of rivers that have their beds sunk below the general level of the surface of the lands, as five or six yards, may be straightened in a profitable manner, are, it is observed, where two reaches, or straight parts, run in a line with each other; but are separated by a narrow neck of an extensive tract.

In this case nothing more is required than that the earth which is taken out of the new cut, should be thrown into the ends of the old bed, by which the stream, both at low water and in time of flood must possess a straight unimpeded course. And by this means the proprietor on this side not only obtains an acquisition of ground in the old river bed for different purposes, but on his own side of the river gains a length of straight ground for the plough or scythe. But at the time this proprietor is thus benefited, the property on the other side may be injured; as by shortening the length, and that of straightening the direction of the river, the force of its stream or current at the upper bend may be considerably increased, and the land there greatly endangered.

Hence Mr. Marshall thinks, that this obvious alteration should not be undertaken, except under the sanction of a commission of drainage, or till the proprietor below be indemnified for the injury that may be sustained. It is suggested, that in the above instance, half of the bed of the old river might be a sufficient indemnification. There is, however, a great variety of small streams and rivulets in the bottoms of steep declivities, that have such winding and serpentine courses, that they might be straightened with not only profit, but vast advantages to the lands on the different sides. In many situations it is disgraceful to see the destruction and injury that is caused by these little winding streams in the time of floods, and when they are in high water.

The proper protection and management of river-banks is unquestionably a work of great interest and importance in many instances; as they are very liable to be extensively destroyed by the streams, and much loss of valuable land to be thereby produced, as well as to be the cause of frequent disputes and litigations between neighbouring landholders. Rivers for the most part form the most tedious, troublesome, and indifferent boundaries of any betwixt landed properties.

The subject of guarding and securing their banks has hitherto been but little understood, either in theory or practice, though it obviously requires equal, if not more attention, than any other rural practice, as being very serious in its consequences, both as to the mischiefs, and the ineffectual, though expensive, modes of preventing them. The practical directions that have been given above should therefore be well considered, as they may save much labour and expence, when well applied; as well as prevent a variety of disputes, and the frequent loss of much useful land. Plans of the methods of accomplishing the work in different cases, may be seen in the second volume of the Farmer's Dictionary.

Before undertakings of this nature are begun, proper plans and estimates of expence and profits should constantly, as has been seen, be prepared, and contracts, where possible, entered into for their execution with persons of experience, always binding them to uphold the works for a certain number of years afterwards; as by these means much money, timber, labour, and unnecessary trouble, will be saved, which would otherwise be thrown away, and the works be improperly managed. Besides, the means will be properly proportioned to the ends which are designed, in all cases. The interest of opposite proprietors will likewise often be shewn to be one and the same, which will greatly promote such works in different instances. See EMBANKMENT.

RIVER *Guards*, terms applied to such piers, mounds, or other solid embankments, as are carried out for the purpose of altering, directing, or confining, the courses of rivers. They are distinguished into common, and what are termed *dwarf* guards; the former being those employed for large rivers, and the latter, such as are made use of where the force of the currents are less violent and less heavy.

With regard to the substances that are most commonly made use of in this intention, they are all sorts of hard weighty materials, such as rough coarse stones of different kinds, large pebbles, heavy pieces of timber secured by piles firmly driven into the ground, and supported behind by coarse gravel stones, or other similar materials, the roots of trees with the earth about them, posts firmly driven in with planks nailed to them, and well banked with strong substances, piles driven in and wattled with fods, being well banked with the same substances. Besides these, various other materials are presented to the attention of the work-

men in different situations and circumstances where these forts of guards are wanting.

*RIVER Guide*, a strong work of the pier kind, carried out on them for the purpose of disposing their streams to take more suitable directions or courses for preventing their mischievous effects on the banks or lands on their sides. See *RIVER-Banks, Securing*.

*RIVER Weeds*, in *Farming*, are such sorts of plants as grow on the sides, and other parts, of rivers. When collected in large quantities, they are highly valuable for the purpose of manure. And in compost with other substances they have been found of much utility in the practice of several writers in the Transactions of the Bath society. And Mr. Crowe, of Lakenham, in Norfolk, according to Mr. Young's agricultural survey of that district, manures four acres annually for turnips, with the weeds of a river that runs by his farm; the plants are chiefly the philandrium aquaticum, and sium nodiflorum, the water hemlock and water parsnip. It is stated that he lays twenty loads of thirty bushels *per* acre, and ploughs in directly; which are as good on sand and mixed loam as the best dung; but not equal on stiff soils; and it is added, that Mr. Bloomfield, of Billingfold, has been in the habit of manuring his turnip lands with weeds fresh from the river, and ploughed in quickly; they have answered as well as yard muck.

But where these sorts of materials are made use of for the purpose of manure, the plants should be removed while in their most succulent green state, and be turned into the soil as quickly as possible afterwards. In the making of them up into composts, a great loss is probably sustained in the extrication and dissipation of the more fluid parts. And it is obvious, that as manure they must be the most useful when applied to the light friable descriptions of soils, as in these they run more rapidly into a state of putrefaction. It is probable they cannot be used with advantage on the stiff heavy soils in their green state. See *MANURE* and *WEEDS*.

*RIVER, Fordable*, in *Military Language*, a river which may be passed without the assistance of any floating machines. In order to sound the ford, and to ascertain the state of it, men on horseback are first ordered to cross. By that means you will be able to know whether any obstacles have been thrown in the way by the enemy; for nothing is more easily effected. The passage of a ford may be rendered impracticable by throwing whole trees in, by tables or platforms covered with nails, and by stakes. The two latter impediments are the most dangerous. But stakes are not easily fixed, and are consequently seldom used. When fords are embarrassed by them, it requires some time and trouble to clear the river; and it is equally difficult to get rid of the inconvenience that arises when wells have been sunk. Whenever there is reason to apprehend such obstacles, it is always best to reach the ford at dusk.

When the prince of Condé, in 1567, resolved to cross the river Seine, the Royalists, who were on the opposite side, endeavoured to prevent his passage by throwing quantities of madriers or thick planks that were nailed together, iron hoops and water-cats into the ford. The Huguenots or Protestants, however, were not diverted from their purpose. Aubigné, a French writer, says, that on that occasion they placed 400 arquebusers upon the bank to protect the men that raked the ford.

This was certainly a singular method which was used to clear a ford, nor could it be done without much difficulty, and no inconsiderable share of danger. The chevalier Foylard has proposed a much safer, and a much easier way, by means of grappling hooks, tied to long ropes, which might

be thrown into the ford. Yet even in this case, observes the writer, the object could not be accomplished if the river were broad, unless the persons employed in the undertaking be under the cover of so heavy a discharge of ordnance and musquetry, that the enemy would not be able to interrupt them, even from an intrenched position on the opposite bank.

With respect to caltrops, the removal of them, when properly distributed at the bottom of a ford, must be attended with great difficulty; for they must render the passage absolutely impracticable, unless they were to sink very deep into the mud and sand, and thus become useless. The men that first enter are in this case the only persons incommoded, but the rest may follow without much hazard.

It sometimes happens, that the bottom of a stream or rivulet is firm and gravelly; when this occurs, the greatest precautions must be taken to escape the effects of caltrops, which would be extremely hurtful to any persons that might attempt to cross. In order to obviate their mischievous consequences, and to render them in a manner useless, a good stock of hurdles must be provided. The soldiers will hand these to one another, force them into the water, and then cover them with stones.

When one or two fords in a river are so situated, that several battalions cannot cross them upon one front, it is then highly prudent to throw a bridge over, either above or below the ford; for a swell may intervene and render it otherwise impassable; add to which, you have the advantage of getting a greater number of troops over at once.

In order to effect a passage for his army over the river Segre, Cæsar gave directions that ditches, thirty feet broad, should be dug in such parts of the banks as might, with ease, receive the water out of the stream, and render it fordable. Having accomplished this object, he found no difficulty in reaching Petreius, who, being in the daily fear of wanting provisions and forage for his men, was on the eve of quitting his position and marching forwards.

The passage of the Granicus by Alexander the Great, is likewise mentioned in history, as an instance of bold enterprise. But however celebrated that act may be in ancient records, we shall not be thought partial to the moderns when we state, that the passage of the river Holowitz by Ch. XII. of Sweden, was equally bold and well managed.

The passage of the Tegliamenti by Bonaparte during his campaign in Italy, is the most celebrated of the present day.

*RIVER Bay*, in *Geography*, a bay on the N.E. coast of Barbadoes; two miles N.W. of Cuckold's Point.

*RIVER's Canal*, an inlet on the N.W. coast of North America, discovered by Capt. Vancouver in the year 1792. This canal extends from S. to N. about 16 miles, and terminates in N. lat. 51° 42'. E. long. 232° 22'.

*RIVER of the West*, a river of North America, which runs into the Pacific ocean, N. lat. 43° 18'. W. long. 122° 30'.

*RIVER Horse*, in *Zoology*. See *HIPPOTAMUS*.

*RIVER Navigations*, in *Hydrology*, denote those which are wholly or in a great part restricted to the ancient channel or bed of a river. See *CANAL*.

*RIVER, New*. See *CANAL* and *COMPANY*.

*RIVERHEAD*, in *Geography*, a township of New York, in Suffolk county, Long island; it was taken from the township of Southold, incorporated in 1792, and contains 1501 inhabitants.

*RIVERIUS, LAZARUS*, in *Biography*, a distinguished physician of the 17th century, was born at Montpellier in the year 1589. He studied in his native university, but was very slow in his attainments, infomuch that he failed in his  
first

first examinations for his degree. This failure, however, occasioned him to redouble his exertions, and he gave sufficient proofs of his acquirements in the following spring, 1611, when he was admitted to the degree of doctor. His attachment to study became very great; and in 1622 he was appointed to the professorship of medicine in the university, an office which he continued to fill with great honour during the remainder of his life. He died in the year 1655. Riverius published "The Institutes of Medicine," in five books, in Latin, of which there are many editions, and which must be deemed a very respectable work for the time. But his principal work, and that which has gained him considerable reputation, is a course of medicine, entitled "Praxis Medica." The first publication of this work consisted of a mere practical treatise, without any pathological discussion, as a sort of text-book, used in his lectures. But finding that many editions of it were printed in France and Holland, he enlarged and improved it, and it was printed in this state at Paris in 1640, and a great number of editions have subsequently appeared, as well as translations into French and English. It treats of most of the diseases to which the body is subject, in seventeen books, in a clear style; but in many places he appears to have borrowed copiously from Sennertus. He published also a work, entitled "Observationes Medicæ et Curationes insignes," which has been frequently reprinted, and is not now without its value. These works have been collected, and published together, under the title of "Opera Medica Univerſa." Eloy observes, that a friar, Bernardin Christin, who had been a pupil of Riverius, compiled some secrets of chemistry, which he published with the name of Riverius; and although it has been clearly proved that he was not the author of these papers, yet they have been frequently printed, in the collections of his works, and separately, under the title of "Arcana Riverii." Eloy Dict. Hist. de la Med.

RIVERS, CAPE, in *Geography*, the N.W. point of the island of Celebes. N. lat.  $1^{\circ} 25'$ . E. long.  $120^{\circ} 30'$ .

RIVES, a town of France, in the department of the Isere, and chief place of a canton, in the district of St. Marcellin; 14 miles N.W. of Grenoble. The place contains 1530, and the canton 12,019 inhabitants, on a territory of 115 kilometres, in 12 communes.

RIVESALTES, a town of France, in the department of the Eastern Pyrenées, and chief place of a canton, in the district of Perpignan; six miles N.N.W. of Perpignan. The place contains 1986, and the canton 10,036 inhabitants, on a territory of  $422\frac{1}{2}$  kilometres, in 14 communes.

RIVET DE LA GRANGE, ANTHONY, in *Biography*, a French Benedictine monk, was born at Confolens, a small town belonging to the diocese of Poitiers, in the year 1683. Afterwards he was sent to study philosophy under the Jacobins, or Dominican monks at Poitiers, where he gave the greatest satisfaction by his application and proficiency. At the age of 21, he became a novice in the abbey of Marmoutier, and took the vows in the year 1705. After completing his courses of philosophy and divinity, he was transferred to the abbey of St. Florence, at Saumur, where his order was establishing a kind of academy, consisting of such members as were most distinguished by their talents and literature, for the purpose of studying the scriptures in their original languages, the councils, the fathers, and the historians of the church, without being shackled by the trammels of the schools. He undertook to write "A Literary History of France," the plan of which he had already conceived. However, before he became wholly occupied on this work, he gave to the public, through the medium

of the Dutch press, another favourite production, entitled "The Necrology of Port-Royal in the Fields, &c. containing historical Eulogies; with the Epitaphs of the Founders and Benefactors of that Monastery, &c." 1723, 4to., preceded by an historical preface. In the year 1733 he published the first volume of his work under the title of "The Literary History of France; treating of the Origin and Progress, of the Decline and the Revival, of Learning among the Gauls and among the French; of their respective Taste and Genius for Literature in each Age; of their ancient Schools, and the Establishment of Universities in France; of the principal Colleges; of the Academies of Sciences and Belles-Lettres, &c." in 4to. This was followed, at different periods, by other volumes, till the author had printed the ninth, which includes the first years of the twelfth century, when he died, towards the beginning of 1749, in the 66th year of his age. This work was afterwards extended to twelve volumes. It has been compared, and not undeservedly, with the "Memoirs" of the learned Tillemont, for accuracy of citation, and depth of research, and it will be found to furnish the reader with much interesting matter, not only on the subjects mentioned in the title, but also relating to the lives of the learned men who flourished in the ages of which it treats.

RIVET, in the *Manege*, is the extremity of the nail that rests or leans upon the horn when you shoe a horse.

RIVETS, in *Agriculture*, a term sometimes applied to a sort of bearded wheat. See WHEAT.

In Essex, throughout all the district of the Roodings, this sort of wheat is found very general, and to yield much better crops on these heavy lands, than any common sort; but on the more light soils the Kentish red is superior.

RIVIERA, or PALESE, in *Geography*, a town of Italy; five miles N. of Bellinzona.

RIVIERA di Levante, a name given to that part of Genoa which extends from the city of Genoa, included in it, to Etruria.

RIVIERA di Ponente, that part of the Genoese territory which extends westward from the city of Genoa to France.

RIVIERA, La, a town of France, in the department of the Doubs; 10 miles S. of Ornans.

RIVIERE, GRANDE. See GRAND River.

RIVIERE Pelote, a town on the S. coast of the island of Martinico.

RIVIERE Salée, a town on the S. coast of the island of Martinico.

RIVIERE Mahaut, La, a town of the island of Guadaloupe, situated in a bay to which it gives name. N. lat.  $16^{\circ} 27'$ . W. long.  $61^{\circ} 46'$ .

RIVIERE de Theyrargues, a town of France, in the department of the Gard; 14 miles N.N.W. of Uzès.

RIVIERE de Thibouville, a town of France, in the department of the Eure, 18 miles N.W. of Eure.

RIVINA, in *Botany*, was so named by Plumier, in honour of the great German systematic botanist; see RIVINUS. Linnæus at first called the genus *Rivinia*, which would have been more correct, but he did not persist in the amendment, nor has it prevailed.—Linn. Gen. 63. Schreb. 87. Willd. Sp. Pl. v. 1. 694. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 273. Juss. 84. Plum. Gen. 47. t. 39. Lamarck Illustr. t. 81. Gært. t. 77.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juss. See PIERCEA.

Gen. Ch. Cal. Perianth inferior, coloured, permanent; of four obovate, obtuse leaves. Cor. none, except the calyx be so called. Stam. Filaments four or eight, shorter than the calyx, approaching each other in pairs, permanent;

ment; anthers small. *Pist.* Germen superior, large, roundish; style very short: stigma simple, obtuse. *Peric.* Berry globose, standing on the reflexed calyx, (which is hardened and become green,) of one cell, and crowned with a little incurved point. *Seed* solitary, roundish, lenticular, rough.

*Ess. Ch.* Calyx coloured, in four deep segments, permanent. Corolla none. Berry with one lenticular seed.

*Obs.* The error of Linnæus in subsequently terming *corolla*, what he had, with indubitable propriety, called *calyx*, is difficult to be accounted for. He is followed by Willdenow, who has misled Dryander and Aiton. The natural order of the plant, as settled by Linnæus himself, determines the question without appeal.

1. *R. humilis*. Downy Rivina. Linn. Sp. Pl. 177. Willd. n. 1. Ait. n. 1. (*Amaranthus baccifer*, circææ foliis; *Comm. Hort.* v. 1. 127. t. 66.)—Stamens four. Leaves downy.—Native of the West Indies. Common in our stoves for above a century past, flowering at most parts of the year, and always decorated with drooping clusters of little berries, of a peculiarly bright scarlet, which make the chief beauty of the plant. The *stem* is bushy, shrubby, three or four feet high. *Leaves* alternate, stalked, ovate, acute, entire, thin, flaccid, light green, downy, about three inches long. *Clusters* from the forks of the branches, solitary, downy, of many small, greenish-white, drooping flowers.

2. *R. levis*. Smooth Rivina. Linn. Mant. 41. Willd. n. 2. Ait. n. 2.—Stamens four. Leaves ovate, pointed, even, smooth. Stem round.—Native of the West Indies. Flowers in the stove, most part of the year. Cultivated by Miller in 1733. *Aiton*. Like the foregoing, but smooth. Margins of the *leaves* purplish. *Flowers* reddish at the outside.

3. *R. brasiliensis*. Wave-leaved Rivina. *Nocca* in *Usteri Annal.* fasc. 6. 63. Willd. n. 3. Ait. n. 3.—“Stamens four. Leaves ovate, undulated and rugged. Stem furrowed.”—Native of Brazil. Introduced at Kew by sir Joseph Banks, in 1790. It blossoms in the stove in June and July. *Stem* shrubby. *Leaves* ovate, or heart-shaped, wavy, smooth. *Flowers* white or reddish. *Berry* round, of a shining red.

4. *R. octandra*. Climbing Rivina. Linn. Sp. Pl. 177. Willd. n. 4. Ait. n. 4. (*R. dodocandra*; *Jacq. Obs. fasc.* 1. 6. t. 2. *R. farmentosa*, &c.; *Browne Jam.* 149. t. 23. f. 2.)—Stamens eight or twelve. Leaves elliptic-oblong, smooth.—Native of the West Indies. Cultivated by Miller, before 1752. It flowers in the stove in May and June. *Aiton*. The *stem* is described by *Jacquin* as very tall, though slender, throwing out long slender shoots, amongst other shrubs and bushes. *Leaves* entire, acute at each end. *Calyx* white, turning to a purplish-red. *Berry* dark purple, the size of a pea, eagerly devoured by birds. *Jacquin*.

*R. paniculata*, Linn. Syst. Nat. ed. 10. v. 2. 899, though retained as such by Murray, in Syst. Veg. ed. 14. 165, is no other than *Salvadora persica*, as cited in Linn. Sp. Pl. 178. This being removed from *Rivina*, the character of “simple clusters” for the remaining species, being common to all, becomes superfluous.

*RIVINA*, in *Gardening*, contains plants of the shrubby evergreen kind, of which the species cultivated are; the downy rivina (*R. humilis*); the smooth rivina (*R. levis*); and the climbing rivina (*R. octandra*).

*Method of Culture*.—All these plants may be increased by seeds procured from the places where they are natives, sowing them, as soon as they are obtained, in pots filled with fresh light earth, plunging them in a hot-bed when in summer, but in the tan-bed of the stove, in the autumn or winter. The earth should be well mellowed during the

summer season, but very sparingly in the winter. They should be carefully preserved in these situations till the seeds vegetate, which is often a great length of time, of course the pots should not be disturbed. When the plants have attained about two inches in growth, they may be removed into separate small pots, filled with light loamy mould, plunging them into a hot-bed, shading them till fresh rooted.

They afterwards require the management of other stove exotic plants.

They may likewise sometimes be raised by layers and cuttings, assisted by the heat of the bark hot-bed.

After these plants have been preserved in the stove of the hot-house till they have attained a good growth and strength, they are capable of being preserved in moderate warmth in winter, and in the warmest part of summer in the open air, in a warm sheltered place.

They afford variety among other potted evergreen stove plants.

*RIVINI FORAMEN*, in *Anatomy*, a supposed opening in the membrana tympani of the ear. See *EAR*.

*RIVINUS*, *AUGUSTUS QUIRINUS*, in *Biography*, an eminent physician, but much better known as a botanist, formed, with Ray and Tournefort, the triumvirate of systematical teachers, who, in the latter part of the 17th century, and the beginning of the 18th, divided the homage of the students of botany between them. Their importance arose from the necessity, which nobody could overlook, of a methodical arrangement of plants; but even the memory of their labours has now almost passed away, because those labours proved, all nearly alike, insufficient for the desired purpose. The services they have rendered to practical science still indeed remain; and the laurels which spring from that soil are unfading. Of these Rivinus may claim a share, though by no means an equal portion, with his English, or his French, contemporary. He endeavoured in vain to bring his German squadrons, with any great force, into the botanical field; while the pupils of Ray, as well as of Tournefort, poured forth in abundance; and by their own proficiency displayed the merits of their respective leaders.

Rivinus was the son of a learned physician and critic, Andrew Bachmann, whose name, according to the fashion of the time amongst literary people, being translated into Latin, became *Rivinus*. The subject of our memoir was born at Leipzig in 1652. He graduated at the age of twenty-four, and fifteen years afterwards obtained the professorships of Phytology and of Botany in his native university. He became a foreign member of the Royal Society of London, and was associated with many other learned bodies, filling his different appointments with honour to himself, till his death in 1723, at the age of seventy-one. His publications shew him in the light of an elegant scholar and a gentleman; and if he betrayed a little impatience in his controversies with Ray, and somewhat of disdainful severity towards Dillenius, who, when a young man, had attacked him; the latter fault, at least, may be pardoned, in one who had attained so considerable a rank in science, and who perhaps had sagacity enough to feel that Dillenius had no systematical talents at all commensurate with his own. Having proposed to himself three great objects; a commodious classification of plants; a compendious nomenclature; and an universal delineation of species, as far as they came under his own observation, he might perhaps not be very patient of contradiction from those whom he thought more able to hinder than to assist him. The same apology may be made for many philosophers, who unjustly incur the charge of petulance, or of pride.

The botanical system of Rivinus is founded on the most elegant and attractive, if not the most solid and important, parts of plants. His classes are marked by the number, the regularity, or irregularity, of the petals. He could not proceed far in this path without perceiving that he made most unnatural, and, as Haller justly terms them, paradoxical, combinations. He therefore asserted, and doubtless believed, the inutility and impracticability of a really natural classification. This principle brought him to one right conclusion, which even the philosophical Ray did not attain, or was afraid to admit, that the old primary distribution of vegetables into trees, shrubs, and herbs, is unscientific and erroneous.

Rivinus published, at his own expence, in 1690, his splendid illustration of the first class of his system, comprising such plants as have a monopetalous irregular flower. These are the ringent flowers of Linnæus, accompanied by the *Scitamineæ*, and even by *Arum*. This part consists of one hundred and twenty-five plates; but though each plate often contains more than one plant, the intelligent reader will perceive how imperfect the catalogue of species must be. A learned *Introductio generalis in rem herbariam* is prefixed; and this introductory part was, at different times, republished in a smaller form. The second part of the sumptuous work of which we are speaking, came forth in 1691. This consists of one hundred and twenty-one plates, of plants with four irregular petals; into which class, by means of some contrivance, and many grains of allowance, are admitted all the papilionaceous tribe, the cruciform genus *Iberis*, the *Euphorbia*, and a few things besides. The genus last named is referred rather arbitrarily to this class, merely because its stalked pendulous germen must be turned to one side, and therefore, in the author's opinion, the flower is rendered irregular. In 1699 the third part, containing flowers with five irregular petals, was given to the world. Even more liberty is taken in the assemblage of genera here than in the former class. The natural order of *umbellifera* is admitted entire; very justly indeed as to practical or philosophical propriety; but with great laxity of artificial principle, many of the plants having regular or equal petals. Next to these follow *Tropæolum*; the irregular *Gerania* (which now constitute the genera of *Pelargonium* and *Erodium*); some leguminous plants not papilionaceous; *Viola*; *Aesculus*; *Delphinium*; *Aconitum*; *Diſtamnus*; and the whole concludes with *Pyrola*, whose slight and partial irregularity of flower has gained it admittance here. This third part of the work of Rivinus consists of one hundred and thirty-nine plates. A fourth part, the *hexapetala irregulares*, consisting of the *Orchideæ*, was finished, but not published, before the author's death; nor indeed have any more than a very few copies of this ever got abroad into the world, so that it constitutes one of the greatest bibliothecal rarities. With respect to utility or beauty, those who are possessed of the transcendent engravings of this favourite tribe in Haller's History of Swiss Plants, may dispense with the figures of Rivinus. The author had prepared several supplementary plates to his work, which never came forth, and of which perhaps the only specimens are to be seen in sir Joseph Banks's fine copy of the whole work, except two duplicate plates bestowed by his bounty on the writer of this article. There is every reason to believe that the copy in question belonged to the author himself, or to his son, as may be gathered from its manuscript additions and corrections. A complete copy, of even the three first parts of Rivinus's book is, indeed, difficult to be met with; for several of the plates having from time to time received additions of seed-vessels, or of entire plants; the earlier im-

pressions of such plates are consequently imperfect. The best copies are required, by fastidious collectors, to have every plate with and without the additions. Haller truly remarks, that the author evidently derived his materials chiefly from garden plants, and having system in view, was more solicitous to exhibit flowers than roots, or the lower part of the herbage; a great defect as to the *Orchideæ* and *Umbellatæ*. We ought, at the same time, to recollect, that the tribes he has selected are among the most interesting, attractive, or difficult, that could have been wished. His scheme of nomenclature deserves high commendation as such, though it proves totally inadequate to the author's purpose, which was to comprehend, in a single word accompanying the generic name, the essential character or idea of each particular species.

As a medical writer, Rivinus has the merit of faithful observation and description, in his treatise *de Peste Lipsienſi*, published in 1680. He wrote also on *Dyspepsia*, on *Intermittent Fevers*, and various other subjects. He did not scruple to attack whatever practice or opinion he found ever so strongly established on the basis of prejudice and ignorance. In this respect his *Censura Medicamentorum officinalium* ranks very high. His commendable aim, in this work, was to clear the *Materia Medica* of its various disgraceful incumbrances; so many of which originated in error, imposition, or superstition. His attempts have been followed up by various men of ability and authority; and it is to the united labour and good sense of such, that the world is indebted for the purified and improved state of our modern Pharmacopeias.

Though not a great practical anatomist, or dissector, Rivinus is said to have discovered a new salivary duct. He left a son, John Augustus Rivinus, who succeeded him as professor, and under whose presidency was published a dissertation, in 1723, on *Medicinal Earths*. This gentleman died in 1725, aged thirty-three, having survived his father but two years. His premature death seems to have prevented the publication of the fourth part of his father's great botanical work, at least for some time. Haller says, Ludwig afterwards edited the plates of the *Orchideæ*, without any letter press; but this publication has never come under our inspection. Rivini Opera. Hall. Bibl. Bot. Aikin's Gen. Biogr. Dryand. Bibl. Banks.

RIVISONDOLI, in *Geography*, a town of Naples, in Abruzzo Citra; 9 miles S.E. of Sulmona.

RIULI, a town of Naples, in Calabria Citra; 16 miles N.N.E. of Cassano.

RIVOGLIOMENTO, Ital. in *Music*, changing the place of the parts of a composition. It is placing the treble or other upper part in the tenor or base, and *vice versa*. This frequently happens in double counterpoint, when the treble serves for the base, or the base for the treble; and in such a manner, as that the harmony, though different, shall remain equally correct and pleasing as in the first arrangement of the parts.

RIVOLGIMENTO, Ital. inversion.

RIVOLI, in *Geography*, a town of France, in the department of the Po, situated at the declivity of a hill on the road from France into Italy by the Cottian Alps, in a fertile country and climate more salubrious, as it is said, than that of Turin. It contains three parish churches and three monasteries. The king of Sardinia had a palace here. The inhabitants are supposed to be about 800; 6 miles W. of Turin.—Also, a town of Italy, in the Veronese; 12 miles N.W. of Verona.

RIVOLTA, a town of Italy, in the department of the Mincio; 4 miles W. of Mantua.—Also, a town of

of Italy, in the department of the Adda; 2 miles S. of Crema.

*RIVOLTA Secca*, a town of Italy, in the department of the Adda; 10 miles W. of Crema.

*RIVOLTARE*, Ital. in *Music*, to reverse; whence

*RIVOLTATO*, reversed. See *ROVERSCIO*.

*RIVOLTELLA*, in *Geography*, a town of Italy; 17 miles E. of Brescia.

*RIUT*, a Russian settlement on the W. coast of America. N. lat.  $65^{\circ} 25'$ . E. long.  $209^{\circ} 36'$ .

*RIVULARIA*, in *Botany*, so called by Dr. Roth from its growing generally in rivulets, is a cryptogamic genus, separated, by that able botanist, from *Ulva* and *Conferva*; to each of which genera some or other of its species had been, by preceding writers, referred.—Roth Catal. v. 1. 212. Sims and König's Ann. of Bot. v. 1. 247. Smith Engl. Bot. v. 25. 1797.—Class and order, *Cryptogamia Alga*. Nat. Ord. *Alga submersa*.

Ess. Ch. Frond gelatinous, firm, destitute of an external cuticle. Frustrification among jointed filaments, lodged in the substance of the frond.

Roth describes eleven species of this genus, in his *Beyträge*, v. 1. 239, translated in Ann. of Bot. above cited. He there also adopts a genus from Micheli, by the name of *Linckia*, whose character is as follows. Frond gelatinous, pellucid, enclosed in a membranous pellucid integument, and stuffed with granules of fructification, disposed in curved beaded lines. Of this he defines four species.

Of his *Rivularia*; *elegans*, n. 5, Engl. Bot. t. 1797, and *tuberculosa*, n. 11, Engl. Bot. t. 2366, are acknowledged natives of Britain; as are two of his *Linckia*; *pruniformis*, n. 2, which is *Ulva pruniformis* of Linnæus, and of Engl. Bot. t. 968; and *Nosloc*, n. 3, which is *Tremella Nosloc* of Linnæus, and of Engl. Bot. t. 461. The *pruniformis* just mentioned, is in the index to Engl. Bot. referred to *Rivularia*; how justly we dare not positively say. In the same work the following species are added to those of Roth. Respecting the marine ones, there may possibly be some difference of opinion as to their genus; but they can scarcely be referred to any other at present established.

*R. Opuntia*. Indian-fig Rivularia. Engl. Bot. t. 1868. (*Fucus Opuntia*; Gooden. and Woodw. Tr. of Linn. Soc. v. 3. 219. *Tremella marina cæspitosa, segmentis tenuibus*; Dill. Musc. 50. t. 10. f. 9.)—Compressed, branched, red, jointed; joints elliptical, confluent. Internal filaments repeatedly forked; their ultimate joints shortened, filled with seeds.—Found on rocks, on the British coast, forming small, creeping, purplish tufts, between high and low-water marks. The fronds are entangled, much branched, compressed, of a spongy texture, but not hollow, composed of elliptical joints. These, when cut transversely, prove full of innumerable forked, beaded filaments, whose joints, near the surface of the frond, are shortest, and full of red grains, presumed to be seeds. We do not pretend that this species answers well to the character of a *Rivularia*. It will probably hereafter constitute a new genus, along with several more, now dispersed in *Fucus*, *Conferva* or *Ulva*, but whose fructification and economy are not sufficiently known, for any decisive measure to be taken concerning them. Among them perhaps is *Fucus Wiggibii*, Engl. Bot. t. 1165; for we are not yet persuaded of its being a real *Rivularia*; nor have we examined it minutely ourselves.

*R. vermiculata*. Worm-shaped Rivularia. Engl. Bot. t. 1818.—Cylindrical, much branched, brown; branches scattered, subdivided, crooked. Internal filaments compound and divaricated; their ultimate branches clustered, beaded, thickened upwards. Fruit obovate, sessile at the

base of the beaded branches.—Found on the coasts of Ireland and the south of England, in summer. A very curious submarine plant, four or five inches high, olive brown, much and irregularly branched, solid, gelatinous, invested with a pale slimy mafs, of minute, jointed, branched fibres, some of which are darker, and beaded, and accompanied by a dark, oval, solitary seed at their base.

*R. verticillata*. Whorled Pink Rivularia. Engl. Bot. t. 2466. (*Ulva verticillata*; With. v. 4. 127.)—Cylindrical, much branched, very gelatinous, pale pink; branches alternate; the ultimate ones very numerous, of equal thickness. Internal filaments whorled, repeatedly forked. Fruit obovate, lateral.—Found on the sea beach of Ireland and Suffex, in summer. Highly gelatinous and tender, of a delicate flesh-colour. Its generic characters nearly accord with the last.

*R. incrassata*. Thick Green Rivularia. (*Ulva incrassata*; Hudf. 572. Engl. Bot. t. 967. *Tremella palustris gelatinosa, damæ cornuum facie*; Dill. Musc. 51. t. 10. f. 10.)—Compressed, much branched, gelatinous, sinuated and toothed, green; thickened at the margin. External filaments loosely tufted, forked, with pale pellucid tips.—Grows on mosses, in pools of fresh water. Whole plant gelatinous and slippery, of a grass green. It seems very near *R. Cornu damæ* of Roth, if not the same.

*R. tuberiformis*. Potatoe Rivularia. Engl. Bot. t. 1956.—Irregularly globose, inflated, pale brown; white within. Seeds vertically disposed in rows at the summits of the filaments.—Grows on rocks and submarine plants, on the south coast of England. When floating it looks like a group of young potatoes. Each plant is hollow, consisting of a thick tender coat. The outside is not, as in the last, covered with pellucid filaments, beyond the seed-bearing part.

*R. atra*. Small Black Rivularia. Roth Catal. v. 3. 340. Engl. Bot. t. 1798.—Hemispherical, solitary, sessile, hard, black. Internal filaments straight, compact, branched, concentric, green; their joints cylindrical.—This is found on mud, or on wooden piles, in salt marshes, or about the mouths of rivers; consisting of black granules the size of mustard-seed. These, when highly magnified, and cut perpendicularly, are found to consist of concentric rows, of more or less pale, green, dense filaments.

*R. calcarea*. Calcareous Rivularia. Engl. Bot. t. 1799.—Hemispherical, sessile, clustered, hard, green. Internal filaments straight, compact, entangled, simple, with scarcely any appearance of joints.—This is found in the beds of rivers, and mountain torrents, in Ireland, Wales, &c. in masses, either separate, the size of a large pea, or aggregate and confluent. Their colour a glaucous green; their substance firm, of simple parallel fibres, or tubes, all conglutinated, as it were, with calcareous earth.

*R. echinulata*. Little Hedgehog Rivularia. (*Conferva echinulata*; Engl. Bot. t. 1378.)—Floating, glaucous, globose, maricated with the points of its concentric, simple, jointed, short filaments.—Found by the Rev. H. Davies, in a lake, in Anglesea, covering the surface in June and July, with a floating mafs of little separate prickly globules, each the size of a pin's head.

*RIVULET*, a diminutive of river.

*RIXAS*, in *Geography*, a mine-town of Brazil, in the government of Goyas; 80 miles N. of Villa Boa.

*RIXDOLLAR*, in *Commerce*, a money of account and silver coin in Holland, Germany, Denmark, and Sweden. In Holland, a rixdollar is worth  $2\frac{1}{2}$  guilders, 50 stivers, or 800 pennings. A pound Flemish is equal to 6 guilders, or  $2\frac{1}{2}$  rixdollars, and is divided into 20 shillings, 120 stivers, or 240 pence Flemish, called also groots; hence a rixdollar is

## RIXDOLLAR.

equal to 8*s.* 4*d.* Flemish, and a gilder = 3*s.* 4*d.* Flemish. A gold gilder, with which accounts are kept in the corn trade, is worth 28 stivers. At Copenhagen accounts are kept in riksdalers or rixdollars of 6 marks, or 96 shillings Danish. In the duchies of Holstein and Sleswig accounts are kept in rixdollars of 3 marks, or 48 shillings Lubs, and at Elfsineur on the Sound, accounts are kept in rixdollars of 4 orts, or 96 skillings Danish. The base rixdollar (sletdaler), which is an imaginary coin, is reckoned at 4 marks, or 64 skillings Danish. A mark is divided into 16 skillings or shillings; and a skilling into 2 fyrkes, 3 wittens, or 12 pfenings Danish. The Danish denominations of marks and shillings bear only half the value of the same denominations in Lubs or Hamburg money: thus, 2 marks Danish are worth 1 mark Hamburg, &c. In silver, specie rixdollars, which pass for 7 marks 6 shillings Danish currency, are commonly reckoned at 6 marks 12 shillings crown money, at the toll on the Sound. There is also the new Holstein currency, coined since the year 1788, consisting of specie rixdollars, at 48 shillings specie, or 60 shillings Holstein currency; and pieces of 32, 16, 8, 4 and 2 shillings specie, or 40, 20, 10, 5 and 2½ shillings Holstein currency. In this money, the Cologne mark of fine silver is coined into 9¼ rixdollars specie, or 11⅞ rixdollars currency.

Any person, whether a native or a foreigner, may open an account at the bank of Copenhagen, on paying 4 rixdollars a year for each folio, and whenever he wishes to have his account settled. Besides, this bank charges a commillion of 1 *per* 1000 for all the money inscribed or transferred in the books. Bank notes are issued of the value of 80, 40, 20, 8, and 4 rixdollars specie; or 100, 50, 25, 10, and 5 rixdollars currency. These are current through the Danish dominions, and they are to be paid off on demand at the bank.

By a royal edict of 1776, settling the rate of coinage, 9½ rixdollars specie are to contain a mark of fine silver; each piece weighing 537.69 schen, Cologne weight, or 447.9 English grains, and being 14 loths or ⅓<sup>1</sup>/<sub>12</sub> this fine; so that it contains 391.9 English grains of fine silver. The rixdollar Danish currency, in current ducats or 12 markpieces, is equivalent to 28.48 German ascs, or 21½ English grains of fine gold; and the same rixdollar, in silver currency, contains 429 ascs, or 318 grains of fine silver. The rixdollar in crowns may be valued at 467 ascs, or 346½ grains of fine silver. Thus the proportion of gold to silver is as 15⅞ to 1. One hundred rixdollars Hamburg banco answer to 113½ rixdollars in crowns, or 123¼ rixdollars Danish currency: the latter may be considered at par with Hamburg currency. The rixdollar currency is = 3*s.* 8½*d.* sterling; and the rixdollar in crowns = 4*s.* 0½*d.* sterling; or a single crown piece = 16*d.* sterling; a current ducat = 7*s.* 5½*d.* sterling; and 1*l.* sterling = 5 rixdollars 2 marks 6 shillings currency, or 4 rixdollars 5 marks 12 shillings crown money.

The most common way of keeping accounts in Germany is in rixdollars of 90 creutzers, or in guildens or florins of 60 creutzers; the rixdollar of account, or (as it is generally called) rixdollar current, is reckoned at 1½ florin, and the rixdollar specie or effective at 2 florins, or 120 creutzers. In Prussia, Saxony, Hanover, Brunswick, and Luneburg, accounts are kept in rixdollars of 24 good groschen, each good grosche being divided into 12 pfenings; or in rixdollars of 36 marien groschen, each marien grosche being divided into 8 pfenings. At Hamburg, Altona, Lubeck, Holstein, and Mecklenburg, accounts are kept in marks of 16 shillings lubs, each shilling being divided into 12 pfenings; and the rixdollar reckoned at 3 marks. Each independent state or city of Germany has its own coins, most of which

may be referred to, or compared with, the following, *viz.*; in gold, the ducat, the pistole, and the gold florin or gulden; and in silver, the rixdollar specie, and its subdivisions. The pistoles are all reckoned at 5 rixdollars current. The gold florins, chiefly current in countries on the banks of the Rhine, pass generally for 2 rixdollars current, and are to contain 18½ carats of fine gold, 3½ carats of fine silver, and 1½ carat of copper: 72 gold florins are to weigh a Cologne mark. Since the establishment of the convention in 1763, the Cologne mark of fine silver is valued at 13½ rixdollars of account, or 10 rixdollars effective, or 20 florins. In small payments, the Cologne mark of fine silver being reckoned at 16 rixdollars of account, or 24 florins, each of the coins is rated 20 *per cent.* higher than its value in convention money; the specie rixdollar passes for 2½ florins, the convention florin for 1½ florin, and the copfstuck for 24 creutzers. According to the Leipsic rate of coinage, the Cologne mark of fine silver was valued at 12 rixdollars of account, 9 effective rixdollars, or 18 florins; 8 specie rixdollars were to weigh a Cologne mark of silver, 14 loths 4 grains fine: in the smallest coins, such as double and single marien groschen, the mark of fine silver was coined at the rate of 12½ rixdollars. These coins are known by the name of "constitution coins:" 100 rixdollars, coined after the Leipsic rate, are worth 111½ convention rixdollars. The fineness of gold is valued all over Germany by dividing the mark fine into 24 carats, and the carat into 12 grains; the fineness of silver, by dividing the mark fine into 16 loths, and the loth into 18 grains. At Hamburg, the reichthaller, or rixdollar, is 3 marks, 48 shillings, or 576 pfenings; the rixdollar of exchange is 2 marks, 32 shillings, or 384 pfenings. The silver coins of this city are rixdollars reckoned at 3 marks specie, which commonly pass for ½ *per cent.* better than banco, or for 3 marks 12 shillings 5 pence Hamburg currency. All sorts of specie rixdollars, when they are full banco weight, are reckoned at 3 marks, with about ½ *per cent.* premium against banco, or at 4 marks light money, with about 33 *per cent.* discount below banco. But the value of a common specie rixdollar, in current money, is 3 marks 12 shillings, and the halves and quarters in proportion.

Accounts are kept in Sweden in riksdaler of 48 skilling, the skilling being subdivided into 12 runstyecken or ore. By the regulations of 1777, the specie riksdaler was to pass for the same value that 6 silver daler, or 18 kopper daler, formerly did; and there were coined whole riksdaler, and pieces of ⅓ds, ⅓d, ⅓th, ⅓th, and ⅓th of a riksdaler. According to the mint regulations, the Swedish specie riksdaler should weigh 609 Swedish ascs, or 451½ English grains, and contains 535 ascs, or 396½ grains of fine silver; it is therefore worth 4*s.* 7½*d.* sterling, and the skilling 1*d.* nearly. For the value of rixdollars, current in various places, according to the mint price of silver in England, see MONEY.

The rixdollar (constitution) of the Austrian dominions has on it the head of the reigning emperor, with name and titles, thus: CAR. VI. D. G. R. I. S. A. G. III. H. BOH. REX; that is, *Carolus sextus, Dei gratia, Romanus imperator semper augustus, Germania, Hierosolyma, Hungaria, Bohemia rex* (Charles VI. by the grace of God, emperor of Rome, ever august, king of Germany, Jerusalem, Hungary, and Bohemia); reverse, a two headed eagle crowned, bearing on his breast the arms of Austria, and in his talons a sword and sceptre; legend, ARCHID. AUST. D. EV. M. MOR. COM. TY. (archduke of Austria, duke of Burgundy, marquis of Moravia, count of Tyrol), with the date; and on the edge of the piece, CONSTANTER CONTINET ORBEM, (he guides the globe steadily).

## RIXDOLLAR.

The rixdollar (convention) has the head of the reigning sovereign, with name and title, thus: M. THERESIA, D. GR. IMP. GE. HU. BO. REG. (Maria Theresa, by the grace of God, empress of Germany, queen of Hungary and Bohemia); reverse, as on the rixdollar constitution; the legend on the edge of the piece of Francis I. is, PRO DEO ET IMPERIO (for God and the empire). On that of Maria Theresa, JUSTITIA ET CLEMENTIA (justice and clemency). On that of Joseph II., VIRTUTE ET EXEMPLO (by virtue and example).

The rixdollar of Hungary has the head, name, titles, and legend, on the edge as above; reverse, the Virgin and Child, and the letters K. R.; legend, S. MARIA, MATER DEI, PATRONA HUNG. (Holy Mary, mother of God, patron of Hungary).

The florin, or half rixdollar, bears the same impressions as the rixdollar; as also the half florin.

The copfstuck, or copstick, (the 20 creutzer piece,) bears the same impressions as the rixdollar, except that there is no legend round the edge, and it is marked 20 on the reverse; the half copfstuck is marked 10.

The rixdollar of Baden has the head of the reigning prince, with name and title, thus: CAROLUS FRID. MARCHIO BAD. ET II. (Charles Frederick, marquis of Baden, &c.); reverse, arms of Baden; legend, AD NORMAM CONVENTIONIS (according to the rule of the convention); and at the bottom, the date, and X EINE F. MARCK (10 pieces to a mark fine).

The thaler or rixdollar of Basil has the griffin, arms, and legend, as on the patagon; reverse, a wreath of laurels, inclosing the value, 1 THALER; legend, MONETA REIPUB. BASILEENSIS (money of the republic of Basil). The half piece is marked  $\frac{1}{2}$  THALER; and the third is marked  $\frac{1}{3}$ .

The rixdollar of Bavaria has the head of the reigning prince, with name and titles, as in the gold coins; reverse, arms of Bavaria, and the date; and on other pieces, the Virgin and Child, with the legend, PATRONA BAVARIE (patroness of Bavaria); but the new rixdollar coined in 1800, bears the arms of Bavaria, and the legend, PRO DEO ET POPULO.

The rixdollar of Brunswick (old) has the head, name, and title of the reigning prince, as in the gold coins; reverse, the horse and legend as on the Carl d'or; but at the bottom there are X EINE FEINE MARCK CONVENTION M. (ten pieces to a mark fine, convention money).

The rixdollar of 1795 has on one side the words 1 SPECIES THALER, and the date; legend, X EINE FEINE MARCK, &c. as above; reverse, arms of Brunswick, with the name and title of the reigning prince.

The rixdollar of Cologne has the head of the reigning emperor of Germany, with his name and titles; reverse, arms of the city; legend, MONETA NOVA LIB. ET IMP. CIVIT. COLON.; that is, *Moneta nova libera et imperialis civitatis Coloniensis* (new coin of the free and imperial city of Cologne); and on some rixdollars, MON. NOVA LIB. REIPUB. COLONIENSIS (new coin of the free republic of Cologne).

In Denmark the ryksdaler (old), coined for Norway, has the head of the reigning king, with name and title, thus: FRIDERICUS V. D. G. REX DAN. NOR. V. G. OR D. G. DAN. NORV. VAND. GOTH. REX (Frederick V. by the grace of God, king of Denmark, Norway, the Vandals, and the Goths); reverse, a lion and battle-axe, with 6 M. (6 marks), and the following legend in the Norwegian language, in two concentric circles, MOD TROSKAB DAPPERHED. OGH VAD DER GIVER ÆRE DEN HELEN VERDENBAND BLANT NORSKE KLIPPER LÆRE, which is thus translated: spirit, loyalty,

valour, and whatever is honourable, let the whole world learn among the rocks of Norway. On the same coin, of a later date, the legend is TROE JOVE MOD OGH VAD DAN KONGENS GUNST KAND VINDE, MENS NORGE KLIPPE HAR MAN SKAL HOS NORDMAND FINDE; that is, true lion's heart and whatever can win a Danish monarch's love, whilst Norway has rocks, shall be found among Norwegianians.

The ryksdaler of 1777 has the king's cypher and a crown; legend, D. G. DAN. NOR. VAND. GOTH. REX, as before; reverse, arms of Denmark; legend, GLORIA EX AMORE PATRIÆ (glory from the love of our country), and the date.

The ryksdaler of 1795 has the head, name, and titles of the reigning king; reverse, arms of Denmark; legend, 1 RIGSDALER SPECIE, with the date.

The ryksdaler of Holstein has the head, name, and title, as above; reverse, arms of Denmark, and 1 SP.; legend, 60 SCHILLING. SCHLESW. HOLST. COURANT (60 schillings Sleswig and Holstein currency), with the date. The pieces of  $\frac{1}{2}$ d and  $\frac{1}{3}$ d are marked  $\frac{3}{4}$  SP. and  $\frac{1}{4}$  SP., and the number of schillings is also expressed; SP. means specie.

The rixdollar of Francfort has varied much in the impressions; most of them bear an eagle; but the reverses and legends are very different in coins of different dates; they may be easily distinguished by the word FRANCKFURT or FRANCOURT, which is to be found on some part of the piece, as also the words AD NORMAN CONVENTIONIS (according to the rate of convention money), and X E. F. MARK, or X EINE FEINE MARK (10 to a mark of fine silver): these last words, within a circle or wreath, form the reverse of the more modern pieces; and coins of 1796 bear likewise the following German legend, AUS DEN GEFÄSSEN DER KIRCHEN UND BÜRGER (out of the plate of the churches, and of the citizens); and on the other side, DER STADT FRANCKFURT (of the city of Francfort).

The rixdollar specie or banco of Hamburgh has on the front the arms of Hamburgh; legend, MONETA NOVA HAMBURGENSIS (new coin of Hamburgh), and at the bottom, 48 SCHIL. SPEC.; reverse, a two-headed eagle crowned, with the name of the reigning emperor of Germany, thus: JOSEPHUS II. D. G. ROM. IMP. SEMP. AUGUST. (Joseph II. emperor of Rome, ever august).

The rixdollar of Hanover has the arms of the reigning king, with his name and title; reverse, a horse running over rough ground; legend, NEC ASPERA TERRENT (neither do rough places deter him), and the date. Some rixdollars bear a figure of St. Andrew on the cross; legend, the king's German titles.

The rixdollar convention of Hesse has the head of the reigning prince, with name and titles, thus: WILHELMUS IX. D. G. HASS. LANDG. HAN. COM. (William IX. by the grace of God, landgrave of Hesse, count of Hanau); reverse, arms of Hesse Cassel; legend, X ST. EINE FEINE MARCK (10 pieces to a mark fine), and at the bottom the word JUSTIRT (adjusted or verified). In pieces of more modern date, 1796, &c. this last word is not to be found, but under the above legend the words BIBERER SILBER (silver of the mine of Biber); and in some pieces of 1770, the words EX VISCERIBUS FODINÆ BIBER (from the bowels of the mine of Biber). The half and quarter rixdollars are marked XX ST. &c. and 40 ST. &c. and under the coat of arms 3 or 4.

The thaler or rixdollar of account has the head, name, and title, as above; reverse, a star with a lion in the centre, and the words VIRTUTE ET FIDELITATE, as before; or the arms of Hesse; the legend, in both cases, is EIN THALER (one thaler); and on the half piece, EIN HALBER THALER.

## RIXDOLLAR.

The rixdollar or 3 markpiece of Lubec has a two-headed eagle crowned, with 48 on its breast; legend, *MON. NOV. IMP. CIVITAT. LUBECÆ* (new coin of the imperial city of Lubec); reverse, arms of the city; legend, 48 *SCHILLING COURANT GELDT ANNO, &c.* (48 schillings currency; the year, &c.)

The rixdollar (fine) of Manheim has the head of the reigning prince, with name and title, thus: *CAR. THE. C. P. S. R. I. A. T. & EL.*; that is, *Carolus Theodorus, comes palatinus, sancti Romani imperii archi thesaurarius et elector* (Charles Theodore, count palatine, high steward and elector of the holy Roman empire); reverse, arms of the prince; legend, *EX VISCERIBUS FODINÆ WILDBERG* (from the bowels of the mine of Wildberg), and *FEIN SILB.* (fine silver) at the bottom.

The piece of  $\frac{2}{3}$  bears the same impressions as the rixdollar, except that it is marked ( $\frac{2}{3}$ ) under the arms. Some pieces of an ancient date bear no head but  $\frac{2}{3}$  in large figures, and under this, *FEIN SILBER*; legend, *DEUS SERVET METALLI FODINAS MONTENSES* (may God preserve the mines of Wildberg); the names and titles are on the reverse, round the arms.

The rixdollar (convention) has the head, name, and titles, as above; reverse, arms of the prince; legend, *AD NORMAM CONVENTIONIS* (according to the rule of the convention); or *10 EINE FEINE MARCK* (10 to a fine mark).

N. B. The coins of Manheim and the Palatinate now bear the same impressions as those of Bavaria, both countries being united under one sovereign.

The rixdollar of Mentz has the head of the reigning prince, with name and titles, thus: *FRID. CAR. JOS. D. G. A. EP. MOG. S. R. I. P. G. A. C. ET EL. E. W.*; that is, *Fredericus Carolus Joseph Dei gratia archiepiscopus Moguntia, sancti Romani imperii pro Germania archi cancellarius et elector, episcopus Wormensis* (Frederick Charles Joseph, archbishop of Mentz, high chancellor for Germany and elector of the holy Roman empire, bishop of Worms); but the pieces of 1796, &c. have their legend in German, thus: *FRIED. CAR. JOS. ERZB. U. KURF. Z. MAINZ. B. Z. W.*; that is, *Erzbischoff und Kurfürst zu Mainz Bischoff zu Worms* (archbishop and elector of Mentz, bishop of Worms); reverse, arms of the bishop; legend, *ZEHEN EINE FEINE MARCK* (ten to a mark fine).

The rixdollar (constitution) of Nuremberg has the head of the reigning emperor, with name and title, thus: *CAROLUS VI. D. G. ROM. IMP. SEMP. AUG.* (Charles VI. by the grace of God, emperor of Rome, ever august); reverse, a view of the city, with an eagle flying over it; legend, *AUGUSTO DOMINO TUTA ET SECURA PARENTE EST* (it is safe and secure under its august lord and father), and at the bottom, *NORIMBERGA.*

The rixdollar (convention) varies in the impressions, some bearing the head, name, and title of the reigning emperor, as above; and others a view of the city, with a sun over it; reverse, a two-headed eagle crowned, bearing the arms of the city on its breast; or a single-headed eagle carrying two escutcheons in his talons. The pieces are marked with the letter N, or the word *NURNBERG*, or the legend, *MONETA NOVA REIPUBL. NORIMBERGENSIS* (new coin of the republic of Nuremberg); and the words, *X EINE FEINE MARCK* (ten to a mark fine), are also to be found in some part of the piece.

The rixdollar of Prussia (coined before 1791) has the head of the reigning king, with name and title, thus: *FRIDERICUS BORUSSORUM REX* (Frederick king of Prussia); reverse, an eagle and military trophies; legend, *EIN REICHS THALER* (one rixdollar). The half rixdollar bears the same

impressions; and its value is marked thus, *2 EINE R. THALER* (two to a rixdollar).

The rixdollar current (coined since 1791) has the head of the reigning king, and the legend in German, as before; reverse, arms of Prussia, with *EIN THALER* at the bottom; but the rixdollar convention money bears the legend, *ZEHN EINE FEINE MARCK* (ten to a mark fine).

The florin of Silesia has the same impressions as on the rixdollar of 1791; but on the reverse it is marked *XXI EINE FEINE MARK.*

The rixdollar of Anspach and Bareuth has the head of the reigning prince, with name and title, thus: *ALEXANDER D. G. MARCH. BRAND.* (Alexander, by the grace of God, marquis or margrave of Brandenburg); reverse, arms of Anspach, &c. with *ZEHN EINE FEINE MARK* (ten to a mark fine); but those of modern date, 1790, &c. bear the impressions of the Prussian coins, Anspach having been at that period ceded to Prussia.

The rixdollar of Ratisbon has the head, name, and title of the reigning emperor, as on the coins of Hamburg and Nuremberg; reverse, a view of the city; legend, *MONETA REIP. RATISPON* (coin of the republic of Ratisbon), and at the bottom, *X ST. EINE F. C. M.*; that is, *X Stück eine feine Colnisch mark* (ten pieces to a mark fine, Cologne weight). The half and quarter rixdollars are marked *20 ST. EINE F. C. M.* and *40 ST. EINE F. C. M.*

The rixdollar of Saltzburg, and its divisions, has the head of the reigning prince, with name and titles, thus: *HEROONYMUS D. G. A. & P. S. A. S. L. N. G. PRIM.*; that is, *Hieronymus Dei gratia archiepiscopus et princeps Salisburgensis, Germania primas* (Jerome, by the grace of God, archbishop and prince of Saltzburg, primate of Germany); reverse, arms of the reigning prince, without a legend; and the copfstuck or 20 creutzer piece differs only in being marked (20) on the reverse.

The rixdollar (convention) of Saxony has the head of the reigning prince, with name and titles, thus: *FRID. AUGUST. D. G. DUX SAX. ELECTOR* (Frederick Augustus, duke and elector of Saxony); reverse, arms of Saxony, with the inscription, *X EINE FEINE MARCK* (ten to a mark fine).

The florin or piece of  $\frac{2}{3}$  bears the same impressions as the rixdollar; but the inscription on the reverse is *XX EINE FEINE MARCK*, and it is marked  $\frac{2}{3}$  at the bottom; the half florin is marked *XL EINE, &c.* and  $\frac{1}{2}$  at the bottom; and the quarter florin is marked *LXXX* or *ACHZIG EINE, &c.* and  $\frac{1}{4}$ .

The rixdollar of Saxe Gotha has the head, name, and title, of the reigning prince, thus: *ERNESTUS D. G. GOTHAN. SAXONUM DUX* (Ernest, by the grace of God, duke of Saxe Gotha); reverse, arms of Saxe Gotha, with *X EINE FEINE MARCK*, as above.

The rixdollar of Sweden of 1752 has the head of the reigning king, with name and title in Latin, thus: *GUSTAVUS III. D. G. REX SUECIE* (Gustavus III. by the grace of God, king of Sweden); reverse, arms of Sweden; legend, *SALUS PUBLICA SALUS MEA* (the public safety is my safety); and on the edge, *MANIBUS NE LÆDAR AVARIS* (that I may not be hurt by rapacious hands). The half rixdollar bears the same impressions.

The rixdollar of 1779 has the head, name, and title, as before; reverse, arms of Sweden, with *I RD.*; legend, *FADERNES LANDET* (the land of our fathers). The divisions of the rixdollar bear the same impressions, but have their value marked on them, thus:  $\frac{2}{3}$  *RD.*,  $\frac{1}{2}$  *RD.*,  $\frac{1}{4}$  *RD.* The rixdollar, and other pieces coined since 1795, have the legends on both sides in the Swedish language. The inscription

tion on the edge of the piece is MANIBUS, &c. as on the old rixdollar.

The rixdollar of Friburg, and its divisions, have the arms of the canton; legend, RES PUBLICA FRIBURGENS (republic of Friburg); reverse, a cross formed by eight F's, and four crowns; legend, AUXILIUM NOSTR. DEUS (God is our help). The quarter rixdollar has, on a square in the centre of the cross, the number 56; and the inferior divisions are marked 28, 14, and 7.

The rixdollar of Treves has the head of the reigning prince, with name and titles, thus; CLEM. WENC. D. G. A. EP. TREV. S. R. I. A. C. ET EL.; that is, *Clemens Wenceslaus Dei gratia archiepiscopus Trevirensis sancti Romani imperii archicancellarius et elector* (Clement Wenceslas, by the grace of God, archbishop of Treves, arch chancellor and elector of the holy Roman empire); reverse, arms of the prince; legend, EPISC. AUG. APP. COAD. ELEC. (bishop of Augsbourg, and other titles), besides the words, IO EINE MARC F. or IO EINE FEINE MARK (ten to a mark fine).

The rixdollar of Wurttemberg has the head of the reigning prince, with name and title, thus; CAROL. ALEX. D. G. DUX WUR. ET T. (Charles Alexander, by the grace of God, duke of Wurtemberg, &c.); reverse, arms of Wurtemberg; legend, PROVIDE ET CONSTanter (providently and constantly), besides the words, IO EINE FEINE MARK (ten to a mark fine).

The rixdollar of Wurtzburg (coined before 1795) has the head of the reigning prince, with name and titles, thus; FRANC. LUD. D. G. EP. BAM. ET WIR. S. R. I. P. F. O. DUX; that is, *Franciscus Ludovicus Dei gratia episcopus Bambergii et Wirzburgii, sancti Romani imperii princeps, Francorum Orientalium dux* (Francis Louis, by the grace of God, bishop of Bamberg and Wurtzburg, prince of the holy Roman empire, duke of East Franconia); reverse, arms of the bishop, legend, IO EIN FEINE MARCK (ten to a mark fine). But the rixdollar of 1795, &c. bears on the front the head of the bishop, with names and titles as above; and on the reverse only the words, IO EINE FEINE MARCK, encircled by two sprigs of laurel; and above it the legend, PRO PATRIA (for the country). See Kelly's Cambist, vols. i. and ii.

RIXI, in *Geography*, a town of Hindoostan, in Bahar; 23 miles S. of Palamow.

RIXOUSE, LA, a town of France, in the department of the Jura; six miles N. of St. Cloude.

RIXTOWN, a town of the duchy of Holstein; seven miles S.W. of Lutkenberg.

RIZAH, a town of Asiatic Turkey, in the government of Trebifond, near the Black sea; 45 miles E.N.E. of Trebifond. N. lat. 48° 9'. E. long. 40° 20'.

RIZEA, in *Ancient Geography*, a town of Asia, in that part of the Colehide, which lay to the left of the Phasis. Procopius says, that it was situated on the frontiers of the empire, and that it was very populous.

RIZIUM, in *Botany*, a name given by the ancients to a peculiar kind of red root brought from Syria, and used by the Grecian women to paint their cheeks red.

The Latin writers, who have mentioned this, have called it *radicula*; and Pliny, who has more than once mentioned it, calls it *herba lanaria*, or *radix lanaria*. This, however, is a very great error, confounding it with the *struthium* of the Greeks. It is probable, that the rizium was no other than the anchusa, or alkanet root, which grows very plentifully in the countries from whence the Greeks had their rizium, and which will answer all the purposes for which they used it.

RIZOA, so named by Cavanilles, Ic. v. 6. 56. t. 578,

after Salvator Rizo, a botanical artist employed by Mutis, is a genus of the *Didymia Gymnosperma*, whose distinctive characters are scarcely sufficiently marked, for us, without a specimen, to decide concerning it.

The species is *R. ovalifolia*, an herbaceous plant of Chili, flowering there in February. *Corolla* pale rose-coloured.

RIZSKOI, in *Geography*, a province of Russia, formerly Livonia, so called from Riga, its capital; bounded on the N. by Revelskoi, on the E. by the government of Petersburg and Pskov, on the S.E. by Polotzkoi; on the S. by Semigalia, and on the W. by the gulf of Riga; about 160 miles long, and 100 broad. N. lat. 56° 30' to 59° 15'. E. long. 24° to 27° 34'.

RIZZIO, DAVID, in *Biography*, born at Turin, but brought up in France, was a good musician, and sung agreeably. His father was a dancing-master. The count de Merezzo took him to Scotland, when he went thither ambassador from Savoy. Rizzio charmed the queen by his talents, which were not confined to music, and there were rumours that she favoured him too much. Henry Stuart Darnley, the queen's husband, had him arrested in the music room of this princess. But it is said, in some accounts, that he was actually at supper with her majesty and the countess of Argyle in her cabinet. Some say that he was massacred in her presence; others assert, that the duke of Rothsay dragged him out of the room and murdered him at the door. There is no doubt but that the queen made useless efforts to save his life; (but to save the life of a cat, a dog, or a squirrel, common humanity would naturally have done as much). However, it is added, that she revenged his death afterwards on several of his assassins. Laborde.

We wished to know what foreigners say of this transaction, as party concerning Mary, queen of Scotland, ran so high at the time, and it still runs, that there is no great credit to be given to either side.

His instrument seems to have been the lute, the general favourite at that time all over Europe.

At Turin, some years ago, among many other musical enquiries, David Rizzio was not forgotten. Imagining, as he was a native of that city, and his father a musician as well as a dancing-master there, if we could find any music composed by either of them or by their Italian contemporaries, it might determine the long disputed question, whether David Rizzio was author of the Scots Melodies ascribed to him. The result of this enquiry is related in the article JAMES I. king of Scotland; which see.

Sir John Melvil, in his Memoirs, tells us that "the queen had three valets of her chamber, who sung in three parts, and wanted a base to sing the fourth part; therefore, telling her majesty of this man, Rizzio, as one fit to make the fourth in concert, he was drawn in sometimes to sing with the rest." This was about the year 1564.

He quickly crept into the queen's favour; and her French secretary happening at that time to return to his own country, he (Rizzio) was preferred by her majesty to that office. He began to make a figure at court, and to appear as a man of weight and consequence. Nor was he careful to abate that envy which always attends such an extraordinary and rapid change of fortune. On the contrary, he seems to have done every thing to increase it; yet it was not his exorbitant power alone which exasperated the Scots; they considered him as a dangerous enemy to the Protestant religion, and held for this purpose a constant correspondence with the court of Rome. His prevalence,

prevalence, however, was very short lived; for, in 1566, certain nobles, with lord Darnly at their head, conspired against him, and dispatched him in the queen's presence with fifty-six wounds. Biog. Diët. vol. xi. p. 94.

RIZZUTO, CAPE, in *Geography*, a cape on the coast of Calabria. N. lat. 38° 57'. E. long. 17° 25'.

ROA, a town of Spain, in Old Castile, on the Duero; 25 miles N. of Segovia.

ROACH, in *Ichthyology*, the English name of a well-known fish, called by the generality of authors the *rutilus* and *rubiculus*, by some the *rubellio*. It is a species of the cyprinus according to the new system of Artedi, and the cyprinus rutilus of Linnæus. It has been deemed, though without much reason, remarkable for its liveliness and vivacity; whence the proverb, *found as a roach*.

In some parts of the world this fish will only live in standing waters; with us it equally thrives in ponds and in deep still rivers, and is remarkable for its numerous progeny; a pond being much sooner stocked with this than with any other fish.

ROACH *Fishing*. See FISHING.

ROACH-Leech, in *Sail-making*, the mast-leech of sails cut with a curve, or roach.

ROACHING of Alum, one of the last processes used in the alum making, and is what renders it fit for the market.

After the alum liquor has been left four days in the cooler, and is sufficiently shot, they drain it out; and taking out the alum, they wash it in a cistern of alum water so strong, that it can scarcely take up any more of that salt, but only cleanses it of its accidental foulnesses. After this washing the alum is put into large pans, and a quantity of water added to it. It is set over the fire to melt in this water and boil a little; then it is scooped into a great cask, where it is suffered to stand about ten days; and it is then fit for the market under the name of *roach alum*, or *roached alum*; the liquor let out of the cooler is boiled up again, and shoots more alum. See ALUM.

ROAD, VIA, an open way or passage, forming a commodious communication between one place and another.

The Romans, of all people, took the most pains in their roads; the labour and expence they were at to render them spacious, straight, smooth, and agreeable, to the very extremities of their empire, are incredible.

Usually, they strengthened the ground by ramming it, laying it with flints, pebbles, or sand; sometimes by a lining of masonry, rubbish, bricks, potshreds, &c. bound together with mortar.

F. Menestrier observes, that in some places in the Lyons he has found huge clusters of flints cemented with lime, reaching ten or twelve feet deep, and making a mass as hard and compact as marble itself; and which, after resisting the injuries of time for sixteen hundred years, is still scarcely penetrable by all the force of hammers, mattocks, &c. and yet the flints it consists of are not bigger than eggs.

Sometimes they even paved their roads, regularly, with large square free-stones: such are the Appian and Flaminian ways, &c.

The roads paved of very hard stones, they usually called *via ferrea*, either because they resembled iron, or because they resisted the iron of the horses feet, chariots, &c.

Roads are either *natural* or *artificial*, *terrestrial* or *aquatic*, *public* or *private*.

ROAD, *Natural*, is that which has been frequented for a long succession of time, and subsists with little expence by reason of its disposition, &c.

ROAD, *Artificial*, is that made by labour of the hand, either of earth or masonry; and in the making of which, several difficulties were to be surmounted; such are most of those along the banks of rivers, and through marshes, lakes, &c.

ROADS, *Terrestrial* or *Land*, are not only those made upon the ground, but also those formed of earth heaped up in manner of a bank, and sustained by spurs, buttresses, and counterforts.

ROAD, *Aquatic*, is a road made in the waters, whether current, as those of rivers, &c. or stagnant, as banks and caufeways, or over morasses, &c.

Under this denomination are also comprehended navigable rivers, and artificial canals. See CANAL.

ROAD, *Public*, or *grand road*, is any common road, whether straight or across, military or royal, &c. *Private* road is that made for the convenience of some particular house, &c. See HIGHWAY.

ROADS, *Military*, so called among the Romans, were grand roads appointed for the marching of their armies into the provinces of the empire, for the assistance of their allies, &c.

The principal of these roads, in England, are Watling-street, Ikenild-street, Foss-way, and Erminage-street. See WAY.

ROADS, *Double*, among the Romans, were roads for carriages, having two pavements or caufeways, the one for those going one way; the other for those returning the other, to prevent clashing, stopping, and confusion.

These two ways were separated from each other by a bank raised in the middle, paved with bricks, for the convenience of foot people, with borders and mounting stones from space to space, and military columns to mark the distance. Such was the road from Rome to Ostia, called *Via Portuensis*.

ROAD, *Subterraneous*, is that dug in a rock with a chisel, and left vaulted. Such is that of Puzzuoli, near Naples, which is near half a league long; and is fifteen feet broad, and as many high.

Strabo says, it was made by one Cocceius, a relation probably of Nerva; but it has since been widened by Alphonfus, king of Arragon and Naples, and made straight by the viceroys. There is another of the same kind in the same kingdom, between Baiæ and Cumæ, called the Grotto of Virgil, because mentioned by that poet in the sixth book of his *Æneid*.

ROAD, in *Rural Economy*, a track or way constructed with some sort of hard materials for the purpose of travelling upon, with carriages, horses, and other animals. Roads are of different kinds, as public and private, or parochial. The first sort may be subdivided into toll and free-roads, and the latter into lanes or bye-roads: there are likewise other sorts of roads, as carriage and horse tracks, &c. It has been remarked by a writer, in the first volume of "Communications to the Board of Agriculture," that the conveniences and beneficial consequences which result from a free and easy communication between different parts of a county and district are so various, and the advantages of them so generally and extensively felt by every description of individuals, from the highest to the lowest; that no labour or expence should be spared in providing them; as, without such ready means of intercourse, all sorts of internal commerce and improvement are either much embarrassed, or wholly at a stand. And it is, indeed, well added, that roads and canals, or navigable rivers, may justly be considered as the veins and arteries through which all improvements flow. To internal commerce and agriculture,

culture, they are as the veins and arteries to the human body. Through these the blood circulates in every direction, and thus keeps alive the animal system; but, if this circulation is by any means checked or obstructed, even in the remotest part, that part soon becomes useless, and sinks into decay, and in some degree is felt throughout the whole body. So it is with respect to the commercial and agricultural systems. Without a free and uninterrupted intercourse, it is impossible they can exist, or at least produce, to the community at large, so many important benefits as they otherwise might have done. How many, for example, are the places, in almost every country, that might be rendered doubly valuable, if the access were practicable and easy. How immense the quantities of the finest timber, perhaps growing in inaccessible woods, which, on that account alone, are lost to society. How many the valuable strata of the richest metals and minerals, which, from the same cause, lie buried and undisturbed in the bowels of the earth; and how many thousands of acres of the most fertile soil, that might be improved and cultivated to the highest degree of perfection, and thus very largely contribute to increase the food and the comforts of man, were the ingress and egress rendered practicable and free. And the value of a farm, consequently the riches, perhaps the strength of a country, greatly depend on an easy and uninterrupted communication by good roads.

And the able author of the "Wealth of Nations" has well suggested, that good roads, canals, and navigable rivers, by diminishing the expence of carriage, put the remote parts of the country more nearly upon a level with those in the neighbourhood of the town. They are, upon that account, the greatest of all improvements. They encourage the cultivation of the remote, which must always be the most extensive circle of the country. Though they introduce some rival commodities into the old markets, they open many new markets to its produce. It is even further observed, that the Romans were so sensible of this, that we are told, the first writer says, they did not think it beneath the dignity of the commonwealth to attend to the conveniences from good roads. That great and wise people, it is said, carried on, at an immense expence, roads, whose remains are to this day the admiration of the curious, from the centre of the empire to many of the remotest provinces. The readier march of their armies was, perhaps, he thinks, their first motive; but the easier intercourse of the several parts of the great empire was another, which they had too much prudence and too much wisdom to overlook. We are also told by Diodorus, Strabo, and other historians, he says, that the famous Semiramis, being so fully convinced of the importance of an easy and general intercourse, applied herself to render the roads practicable throughout the whole extent of her empire.

Mr. Donaldson also states, that, in an agricultural view, the benefits derived from good roads are incalculable. Before the establishment of turnpike roads in England, many parts of that kingdom, like the highlands of Scotland, were scarcely accessible. Coal, manure, grain, &c. as is still the case in many parts of Cornwall, were carried on horses' backs. Where waggons were used, seven or eight horses were necessary to draw about two tons, and seldom were able to proceed above twenty miles in a day. Now, where turnpikes are established, or other means used for keeping the roads in a proper state of repair, the same number of horses will draw at least five tons, and travel nearly double the distance, with much more ease. How absurd, then, continues he, for any person to scruple the payment of an in-

considerable toll, when the saving is so great and so evident; where the tear and wear in one case are not one-twentieth part of what they are in the other!

It is likewise contended by Mr. Beatson, in respect to the turnpike laws in this country, that they are liable to many exceptions; for although immense sums of money are annually levied for the purpose of making and repairing the highways, yet, either from bad management, from party influence, or from the chicanery and ignorance of surveyors and contractors, the roads in many places are not only laid out in the most absurd direction, but are so badly constructed, and kept in so wretched a state of repair, that they are almost impassable. It is surprising that in so enlightened a country, and where the turnpike laws have so much engaged the attention of many very ingenious men, those laws should still remain so very defective; more especially as there is hardly a country gentleman who attends a turnpike meeting, but considers himself completely master of the whole business and management, as well as of the making of roads; at least, if we may judge from the violent disputations and bickering that frequently happen at these meetings, where a proposed new line of road, or perhaps the repair of an old one, will sometimes be contested with as great keenness and vehemence, as if the parties were contending whether Great Britain shall be a monarchy or a republic. And it is contended, that it too often happens party influence rules the proceedings at such meetings, and that those who are entrusted with the management of this business, delegate their powers, and trust the inspection and whole management and direction of the roads to some ignorant or pretended surveyor; who, almost to a certainty, will impose upon them, especially if he is empowered to settle with contractors; and thus the business of the public, in one of its most important concerns, is either altogether neglected, or terminated according to the convenience of the strongest party, without any regard to the interests of the community at large. In support of this assertion, he has only to refer to many parts of the principal thoroughfares in Britain. In some, it will be observed, the roads are directed in the most irregular zigzag manner, through a level part of the country, where they ought evidently to have gone straight forward. In other places, the traveller and the public, and the poor overloaded horse, are obliged to submit to all the inconvenience, the labour, and the fatigue of ascending and descending the steepest hills, when they might have gone, with the greatest ease and comfort, on a level road, by proper attention in the first making and laying them out. He is, however, far from thinking it would either be just or proper to force a road unnecessarily, through any part of a gentleman's property without his consent, unless for very powerful reasons indeed.

If to avoid a deep ascent, or to shorten the distance considerably, and that there is no other way to do so, in that case there should be no hesitation; but if the advantages to the public are not very material, and that another line can be adopted, nearly as good, which will do less injury to an individual, the latter line should unquestionably be preferred in all such cases of laying out roads.

It should be a general maxim, he thinks, that private considerations ought, in all cases, to give way to public convenience and advantage. Society, says he, is formed for the mutual and general benefit of the whole, and it would be a very unjust measure to incommode the whole, merely for the convenience, or perhaps to gratify the whim or caprice of an individual. However, the property of an individual ought by no means to be taken to serve the public,

public, without allowing him, not only the full value, but more than the value proportioned to the inconvenience or injury he may sustain by the measure.

But he contends, farther, that while the present turnpike laws remain in force, and the common mode is practised of choosing surveyors annually, or by rotation, without the smallest regard to abilities or experience, it cannot be expected the public convenience will be so much attended to as it ought to be; neither is it to be expected, that the generality of surveyors, so chosen, can know the proper directions to give in making or repairing roads, nor the proper manner of making estimates, so as either to conclude an agreement with an artful contractor, or to form a correct judgment of such proposals as may be made. From these disadvantages, it is inconceivable the loss that may be occasioned, or the mischief that may be done by an ignorant and inexperienced surveyor. For he is decidedly of opinion that a surveyor of roads should be a man of considerable abilities, and of the strictest honour and integrity. A man not apt to be swayed by party influence, or by private or personal considerations; for if he once allows himself to be led away or biased by those, or to act in any manner inconsistent with the public interests, he is unfit for that office. He ought not to be a man, who has all his life-time been confined to the narrow limits of a single district or county, or who has suddenly, or by a slender recommendation, been brought forward as a person qualified for so arduous an undertaking. He ought to have seen, in various places, the different systems adopted in the management and construction of roads, and to have made it a particular object of his attention, the judging of the best and most advantageous practices, under the particular circumstances of different cases. And besides these, there is another probable reason why, under the present system, the public roads cannot be so impartially managed and conducted as they ought to be, in the unlimited power given to country gentlemen over the roads in the county or district in which they live. Many of those gentlemen, for their benevolence and liberality, are truly deserving of every praise that can be bestowed upon them; but, however honourable and respectable they may be, and however desirous to promote the public good, it would be doing an injustice to human nature to suppose they can view, with impartial eyes, the fine plantations, the beautiful inclosures, and other improvements, they have made on their estates. We may as well imagine, that a doting mother can coolly and deliberately see an incision made in the skin of her darling child, however much it may be benefited by the operation, as that a country gentleman can with indifference behold a turnpike road carried through an inclosure, which he himself has been at the pains and the expence of adorning. He adds, that so situated, it is natural to believe this gentleman would wish that road to go in any other direction, even though it should not be quite so convenient to the public. He will not only use his own persuasion and endeavours to point out arguments against its coming that way, but he will even endeavour to prevail on his friends to exert themselves also, and thus a party is often formed in opposition to the public interest; and if he is a man of opulence and power, and generally respected, it is more than probable his influence will prevail in this business.

It consequently appears to him necessary, in order to obviate these abuses and inconveniencies, that there should be a controlling power over the measures proposed by country gentlemen respecting turnpike roads: for to allow those gentlemen to decide ultimately on the laying out a

new road through their own lands, or even on the distribution of the money to be expended in repairing old roads, is, in fact, making them judges in their own cause. In short, it is an object so truly important to the interests of the community at large, and of the kingdom in general, to procure the most easy, safe, and expeditious, and the least expensive intercourse with every part, by means of the best roads, that it is a measure, he presumes, highly deserving the attention of the legislature; and which, from the great extent of business, would probably require a board, with proper surveyors appointed by it, for the purpose. If some plan of this nature were adopted, we should then hear no more of those numerous complaints that are so often made respecting the abuses committed in the management of turnpike roads, and of the money levied at the toll-bars, at many of which, it is said, by the author of the "Wealth of Nations," the money levied is more than double of what is necessary for executing, in the completest manner, the work which is often executed in a very slovenly manner, and sometimes not executed at all.

But in respect to the improvement of both the public and private roads, the following hints have been thrown out in the able Agricultural Survey of Shropshire. In lieu of surveyors in each parish (who are generally chosen in turn, and consequently have neither time nor experience sufficient to act properly, and are generally not inclined to exert themselves by enforcing the duty, &c.), the writer would propose for the magistrates to have power to appoint a proper surveyor with a salary, who should act under their direction, and be amenable to them for his conduct; such surveyor to undertake the arrangement of a certain district (say ten miles square), whose duty it should be to employ deputies, to call in and see the statute duty done under his direction: by this means the forming of the roads, which is the first principle, would be done in the most approved method, and the statute duty regularly called out. There may be an inspector, an inhabitant in each parish, appointed, and chosen yearly, whose interest it would be, as well as his duty, to act as a check upon the general surveyor and his deputy: this office, being easy, might be filled by one of the most liberal persons in the parish. He apprehends that an arrangement of this sort would very soon insure good private roads. And something like the following would, he thinks, procure good turnpike roads also; namely, the trustees of all the turnpike roads throughout England, to be obliged to erect weighing engines at all their gates or bars, at which tolls are received, on or before the 24th day of June next, the expence of such erections to be repaid to them, by their being empowered to add to their present respective tolls any sum to be paid by such carriage to be weighed, not exceeding so much as has been heretofore paid within one year last for the tolls; such sums to be paid, until all expence of erecting the said engines shall be fully repaid. The account of such repayment to be made out and settled by the clerks and gate-keepers belonging to the respective roads, and to be attested upon oath before two justices of the peace. And from and after the said 24th day of June next, it may be lawful for all carriages to be drawn with any number of horses along any turnpike road. But to prevent the injuries done to roads, by the great burdens too frequently drawn along them, it should be enacted, that from and after the said 24th day of June, it should be lawful for all trustees appointed by any act or acts of parliament, for the repair of any turnpike road, or any five or more of them, and they should be required at a public meeting, to be held  
for

for that purpose on or before the 24th day of April next, to order to be erected at all the gates and bars which they have erected, or shall erect, for the receiving of tolls, or upon any part of the road within their respective jurisdictions, and at such a distance from any turnpike, bar, or toll-gate, as they shall think requisite and expedient to order and cause to be erected, a crane, machine, or engine, proper for the weighing of carts, waggons, or carriages conveying any goods or merchandize whatever; and by a writing signed by them, or any five or more of them, to order all and every such carriage or carriages which shall pass loaded through any such gate or bar, to be weighed, together with the loading thereof; and for them, or any five or more of them, or for any person or persons empowered by any five or more of them, to receive and take, over and above the tolls already granted, or hereafter to be granted, the sum of 10s. for every hundred weight, 112lbs. to the hundred, which every waggon or cart hereafter described, together with the loading thereof, shall weigh over and above the weights hereafter allowed to them respectively; that is to say, to every waggon or four-wheel carriage, having the fellies or rollers of the wheels of the breadth of sixteen inches, eight tons in summer, and seven in winter: to every waggon or wain, having the axle-trees thereof of such different lengths, that the distance from wheel to wheel of the nearer pair of the said wheels be not more than four feet two inches, to be measured at the ground, and that the distance from wheel to wheel of the other pair thereof be such, that the fore and hind wheels of such waggons and wains shall roll only one single surface or path of sixteen inches wide at the least, on each side of the said waggons or wains, and having the fellies thereof of the breadth of nine inches from side to side at the bottom or sole thereof, six tons ten cwt. in summer, and six tons in winter: to every waggon or four-wheel carriage, having the sole or bottom of the fellies of the wheels of the breadth of nine inches, six tons in summer, and five tons ten cwt. in winter: to every cart, having the fellies of the same dimensions, three tons in summer, and two tons fifteen cwt. in winter: to every waggon, having the sole or bottom of the fellies of the wheels of the breadth of six inches, four tons five cwt. in summer, and three tons fifteen cwt. in winter: and to every such waggon, so constructed as to roll, and actually rolling a surface of eleven inches by the wheels thereof, five tons ten cwt. in summer, and five tons in winter: to every cart having the fellies of the same dimensions, two tons twelve cwt. in summer, and two tons seven cwt. in winter: to every waggon, having the sole or bottom of the fellies of the wheels of less breadth than six inches, three tons fifteen cwt. in summer, and three tons twelve cwt. in winter: and to every cart, having the fellies of the same dimensions, one ton fifteen cwt. in summer, and one ton to twelve cwt. in winter. And if such trustees as aforesaid shall neglect to erect such engine at their respective gates by the said 24th day of June, then it shall and may be lawful for any mortgagee or mortgagees of the said gate or gates to erect such engine or engines, and to take upon them the same power as the said trustees were by the act invested with, and under the same regulations, on or before the 29th day of September next; and if the said trustees and mortgagees shall neglect to erect such engine or engines by the respective times hereinbefore stipulated for erecting the same, then it shall and may be lawful for all horses, carts, and other carriages, from and after the said 29th day of September next, to go through and pass along such road or roads, without any obstruction or payment for tolls whatsoever, until such

trustees or mortgagees shall erect such weighing engine or engines as aforesaid, and occasion the same to be regularly used; any thing contained within the respective acts for turnpike roads to the contrary notwithstanding.

And it is usefully remarked, in respect to the effects of these regulations, that, first, the weighing engines will sufficiently prevent carriages of all sorts being overloaded, which will be a preservation of the road, whereas, the restraint upon the number of horses does not answer the purpose; for a short and overpowered team does more damage to the roads, than a greater number of horses, which draw easy, and consequently pass along much quicker. That disagreeable restraint will be thereby made unnecessary, which empowers and encourages some poor indolent wretches to wander about the country with their ready printed notices, to catch a prey, which, when got, is lavished away in drunkenness, debauchery, and disorder; and if they fail in their lawful attempt, which is often the case, and perhaps distressed to the greatest degree, being despised by persons of all denominations, pursue poaching and fowl-stealing, which lead to greater acts of thievery, of which there are many instances; for all the convictions are grounded upon the poor wretches as above described, being by the law allowed to be credible witnesses, who obtain the reward to the amount of 5*l.* or more, when the team-owner's servant or servants are all deemed prejudiced; so that, as the act now stands, no one is safe from these convictions.

Besides, the occupiers of farms in general, particularly those upon the middling-sized ones, find themselves, it is said, very much oppressed and injured by the law now subsisting for regulating the turnpike roads, by their being restrained from drawing more than four horses in waggons, the fellies of the wheels thereof being under six inches broad. Were farmers permitted to draw any number of horses, it would be of great public utility in lowering the price of those animals, which is now enormously high; the farmer would find it his interest, as formerly, to keep breeding mares, which, with the colts they breed, may be made useful great part of the year, provided they may be worked easy. The law, as it now stands, acts nearly as a prohibition to farmers breeding horses; for a breeding mare, or a colt under five years old, is not fit to draw one of four in a waggon, with no more than sixty bushels of barley or wheat, which is the common load of the Shropshire or Staffordshire farmers, neither of which bring more than two tons, which is considerably under the weight the present act allows to be drawn on the turnpike roads in winter. Before the said turnpike laws were in force, the farmer's team, to draw his sixty bushels of wheat or barley, consisted of six in number, two of which at least were mares, either in foal or sucklers, two colts, one of them two, the other three years old, which were never oppressed or hurt by their work; consequently a succession came on, and the owner had one or two good sound colts to sell off every year to the harness or draft, as they best suited. Good waggon horses were then bought at from 10*l.* to 15*l.* each, which are now, by their scarcity, from 25*l.* to 35*l.*; and those for the coach, that is, the light active half-blood horses, are from 40*l.* to 60*l.*

And another evil occasioned by this law is, that such farmers are obliged to keep horses of the largest size, which consume the produce of much land, by eating a large quantity of corn, when the smaller horses, working easy, seldom eat any. It is conceived by the same writer, that upon this principle, a law for regulating roads may be enacted, so as to answer every good design of the present, and at the

same time relieve those individuals who are exceedingly injured, and also be of general utility.

It is likewise remarked in regard to private roads, that they are by no means properly attended to; and which may be attributed to the general highway act being so easy of evasion, that every farmer is able to avoid doing statute duty, or at least next to none. Nothing is more valuable than *time*, especially to a man of business; and a farmer who executes the office of surveyor of the highway, *impartially and effectually*, will find he must neglect no small part of his own business; and after all he might, perhaps, have been as little out of pocket had he done the whole work with his own team and labourers. It is stated, that there is no trick, evasion, or idleness, that shall be deemed too mean to avoid working on the road; sometimes the worst horses are sent, at others a broken cart, and a boy, or an old man pait labour, to fill; they are sometimes sent an hour or two too late in the morning, or they leave off much sooner than the proper time, unless the surveyor watch the whole day. It is true, that redress may be had by application to a magistrate; but then how often causes of complaint occur; and how many days must be lost to bring each home to the offender; who, *from custom*, thinks he is doing no harm; besides the constant breach of good neighbourhood that must be occasioned by these petty litigations. It is suggested that a remedy might easily be had in the following manner. Abolish all personal service upon the highways. Let surveyors be appointed, as at present, who should have power, under the authority of two magistrates, to raise, by rate, certain sums that may be necessary for the repair of the roads within the respective parishes and townships, and to account for the same at going out of office at the year's end. The farmer, who acts as surveyor, might then be able to repair the highways when most convenient to himself, and when he could give attention to them without any interruption or impediment, whereas at present some duty is given up, or nearly so, from the difficulties arising in collecting it. On the same principles, the author of the Present State of Husbandry in Great Britain contends, that an act of parliament should be introduced, for the purpose of rescinding the ancient laws respecting statute labour; which have in every instance been found ineffectual, and to establish other general rules and regulations more likely to answer the purpose in the new improved state of the country. He adds, that the existing acts of parliament respecting the making and repairing roads, where the justices of the peace cannot commute the statute labour, are not sufficient for the purpose of raising a fund sufficient for keeping the roads in repair. Where the justices of peace have it in their power to assess the inhabitants in a sum of money in lieu of the statute labour, it is in general not the want of means, but the misapplication of that means, or negligence in the general management, that is the cause why the parish roads are almost every where a disgrace to the country. The imperfect and indifferent modes of executing the statute work, as stated above, render it necessary, it is supposed, that those statutes enforcing the performance of this necessary duty should therefore be abolished; and in every county the justices of the peace ought to be invested with the power to assess the inhabitants of the district by some equitable *ratio*, whereby they would pay only in proportion to the benefit they received. Were this generally done, as is the case in several parts of Scotland, the counties divided into districts of such size, that the proprietors could conveniently meet as occasion required; the money arising from the commutation act collected by one person, who should be allowed a certain *per*

*centage* on the sum collected, be continued during good behaviour, and be responsible for his conduct to the gentlemen of the district; the money so collected be afterwards expended under the direction of these gentlemen, and the whole be subject to the review of the quarter-sessions; the parish roads would, it is supposed, soon be materially improved. If to these regulations a power were added to mortgage the sum arising from the commutation of the statute labour for such a number of years, and to such an extent, as was found necessary to put the useful private roads in a perfect state of repair, they might, it is supposed, in a few years, be made the reverse of what they are at present. The last measure would be found the most effectual of any that could be adopted, and is probably the only one that can be referred to for the purpose of effecting an immediate and general improvement.

It has likewise been remarked by the author of the "Landed Property of England," in respect to the improvement of farm-lands by these means, that the art of planning, forming, and repairing roads, is a subject with which, for various reasons, every manager of a large estate ought to be familiarly conversant. It is not enough for him to know the theory, or general principles, of the art. It is necessary that he should study it practically in the particular district in which he is placed; and with the given materials that it happens to afford; as by these means he can only be capable of executing the business with the greatest possible advantage. In this business a most material point, whether in the *laying* out of *new* roads, or *improving* such as have been long established, is that of giving them all the advantage in direction and other circumstances that the peculiarity of their nature and situation admit of. It has been stated by the above writer, that most of all the old roads of the kingdom (the remains of the Roman ways excepted) owe their present lines to fortuitous circumstances. Many of them were, no doubt, he thinks, originally foot-paths; some of them, perhaps, the tracks of the aboriginal inhabitants, the patriarchal savages, who lived by hunting; or of the pastoral tribes, who travelled with their flocks and herds from pasture to pasture, as herbage and browse invited; or of the first settlers, between bidding places which may not now exist. And that these incidental foot-tracks, especially when they led through woods, became, as the condition of society advanced, the most convenient horse-paths; as we not unfrequently find at the present day. Consequently, that in this state of society, before wheel-carriages were in use, many of the lands of the kingdom were appropriated, by which circumstance those fortuitous lines of roads became fixed and unalterable; there being no other legal lines left for carriage roads, than those incidental horse-ways, or small tracks. He supposes, that in this account of the probable origin of roads, we have, at least in part, the cause of the crookedness, as well as the steepness, of carriage roads, between the places which are now inhabited: for true it is, that the traveller is not unfrequently led down one steep to make an angle, and ascend another; while the hang of the hill would conduct him nearly on a level, and by a more direct line. But, admitting that a cluster of habitations heretofore stood at the angle, the seeming absurdity ceases. He adds, that formerly, it is probable, the zigzag direction of roads, between towns and villages, was much more observable than at present. In more modern times, and since the legislature wisely interfered with respect to appropriated lands, many improvements of lines have been made. And, by the general laws which have more recently been passed, magistrates are invested with authority to alter established lines. So that

that now, the expence of alteration may be said to be the only obstacle, in ordinary cases, to the perfection of the lines of roads in this country. And which is, of course, a circumstance that has had much effect in improving the convenience of travelling.

And it is suggested, in respect to the direction of roads, that the most perfect line is that which is straight and level. But this is to be drawn in a country only which is perfectly flat, and where no obstructions lie in the way:—joint circumstances that rarely happen. Where the face of the country, between two points or places to be connected by a road, is nearly but not quite level, by reason of gentle swells that rise between them, a straight line may be perfect;—may be the most eligible under these circumstances. But where the intervening country is broken into hill and dale, or if one ridge of hill only intervenes, a straight line of carriage road is seldom compatible with perfection. And that in this case, which is nearly general, the best skill of the surveyor lies in tracing the midway between the straight and the level line. Here the level line of perfection, for agricultural purposes, is to be calculated, by the *time* and *exertion* jointly considered, which are required to convey a given burden with a given power of draft from station to station. On great public roads, where *expedition* is a principal object, time alone may be taken as a good criterion. It is likewise added, that the most regular method of finding out the true line of road, between two stations, where a blank is given,—where there is no other obstruction than what the surface of the ground to be got over presents,—is to ascertain and mark, at proper distances, the *straight line*; which is the only certain guide to the surveyor. And that where the straight line is found to be ineligible, each mark becomes a rallying point, in searching on either side of it for a better. If two lines of equal facility, and nearly of equal distance from the straight lines, present themselves, accurate measurements are to determine the choice. If one of the two best lines, which the intervening country affords, is found to be easier, the other shorter, the ascent and the distance are to be jointly considered, the exertion and the time required are likewise to be duly weighed. Further, also, the nature of the ground, the source of materials and, generally, the comparative *expence* of forming the road by two doubtful lines, as well as their comparative *exposure*, are to be taken into consideration. A long line of road, across a broken country, should not be hastily drawn or determined upon by the directors of this sort of business.

But in regard to the most difficult and troublesome part of this sort of work,—the necessary management in the ascent of hills,—it is observed that, whether in laying out a fresh line, or in altering an established one, modern road surveyors, like many other reformers, have run from one extreme to another. To do away the absurdity of going up one steep and down another, to ascend a third in order to reach the required elevation (a common occurrence on fortuitous roads), they have ingeniously, but very injudiciously, given a uniform rise from the bottom to the top of the ascent. In the theory of mechanics, and where mechanic powers only were to be used, a regularly inclining plane would be perfectly proper, in a case of this kind. Where the requisite power is to be applied by rational beings, the same principle, though not altogether perfect, may be allowed; but when the moving power is neither purely mechanical, nor in a sufficient degree rational, but an irregular compound of these two qualities, the nature and habits of this power require, he thinks, to be consulted. It is, he conceives, one of many instances, which shew the impropriety of applying purely mechanical principles, in agricul-

ture and rural concerns, in which they are to be combined, not only with the power but the will of the animals. No man who has been accustomed to drive a road team, or in the habit of seeing one driven in a hilly country, and who properly regards what he sees, would lay out a long line of ascent without one or more breaks, or convenient resting-places; in which the animals of draft may relax at their ease, and set off again without difficulty. He, however, observes, theory will readily suggest that, by a drag-staff, or pail, a carriage may be securely stopped on the steepest ascent. But practice well knows the danger of checking the efforts of beasts of draft while they are struggling against the collar. For if they possess any habits, or even the seeds of restiveness, nothing is, he contends, more likely to encourage, or produce it, than suffering them to stop under the difficulties of draft. Besides, those which are true to their work, well knowing the extraordinary difficulty to be overcome, in putting a carriage at rest into motion in such a situation, stop under a degree of anxiety; while the more spirited and irritable stand on the rack, and tremble at the apprehension of the painful effort they have to make. But let them see an end, or a respite, of their endeavours, and they will struggle with willingness. A rest, after the difficulty is surmounted, comes as a reward for their exertions. But where the natural surface of the ground is well studied in any given case, there will seldom, he supposes, be much difficulty in assigning the places proper for rests; so as to make the road not only easier for carriages of burden, but safer and more pleasant to travellers, as well as more lightly: besides being better to be kept in repair, than an uniform descent; by reason of the flatter stages being checks to the surface water, and convenient places to get rid of it, without injury to the face of the road. But where such breaks do not occur, the line of ascent should be uniform; or as nearly so as the natural surface, or immoveable obstructions of the acclivity to be surmounted, will allow in the particular case.

Likewise in the setting out of these lines, the common level is to be set by an observation from the bottom to the top of the ascent (these points having been previously determined on, by the given circumstances of the general line of the road), or from station to station where a clear view cannot be had between the extremities; and the degree of ascent, thus ascertained, is to be marked with a pencil upon the instrument that is made use of for the purpose. And by this mark it is advised to trace a rough line along the face of the hill; in order to determine, with sufficient truth, respecting the proper breaks, or resting-places, that may be required; endeavouring to fix upon such natural breaks in the slope as are situated in, or sufficiently near, the general line of ascent. And that when this has been done, to ascertain, by similar observations, the exact angle of elevation, or degree of steepness of each rise, or length of ascent between the breaks, &c. by these means procuring an unerring guide, in marking out and forming the base or bed of the road; without the risk of incurring unnecessary labour and expence in doing the work twice over to bring it to the truth, or a state of suitable exactness.

But it is well remarked by Mr. Marshall, that the best services of the road surveyor lie in avoiding, not in surmounting hills. And that in a long line of road, between places of nearly equal elevation, this may often be done. There are instances of the most public roads going over the tops of hills, where lines of equal length might be traced along their bases; and the difficulty and danger of ascending and descending the steeps be avoided by such means.

Very much attention has lately been bestowed on this department

partment of the road-maker's business, especially in the more northern parts of the kingdom; but much is still left to be accomplished, especially in the western districts of the southern parts of the island, where an attachment still remains to the original lines or directions.

And it is suggested by Mr. Beaton in the paper above alluded to, that the business of laying out the lines of roads may, in fact, be reduced to three simple principles; those of fixing upon the *shortest*, the *most level*, and the *cheapest* directions, for which, though apparently very easy of execution, from the frequent occurrence of circumstances that render it necessary to deviate from them, the knowledge and experience of the surveyor are found requisite. The first requisite from its being a straight line, is often necessary to be departed from in order to avoid the removal of expensive obstacles, such as hills, rocks, water, and morasses. The second is of vast importance, and should invariably be adhered to, if possible, even though the other two should, in a certain degree, be given up; for it is infinitely better to go a considerable way about to obtain a level road, than to go straight forward and be obliged to take an ascent; but it may, in some cases, be preferable to ascend a gentle rise, in order to obtain a good hard bottom, and a road easily made, than to go on a level through a swamp, or piece of water, which would require a much greater quantity of materials, be much more difficult to keep in repair, and occasion a great deal more expence. It is not the most hilly line to appearance that is always to be rejected as being the least level; for the steeper and shorter some hills are, it will be the easier to obtain a level road in that direction, by cutting down the summits, and laying the materials taken from them in the vallies or hollow parts, which, in many instances, may be done with great facility. And the third, or the least expensive line, is also frequently given up, in order to obtain one or both of the other two. It is therefore concluded, that much depends on the skill and ability of the surveyor, who, before he finally determines on a line of road, ought to make himself perfectly master of every part of the intermediate and adjacent country; nor should he rashly determine at once, but should examine repeatedly, over and over again, whether no other line would be better than that he first thought of.

And with respect to the parts or divisions of which a public road should consist, it is obvious that they should vary in some measure, according to the nature of the traffic or business which is carried on upon them, the situation in which they are placed, and the particular circumstances of the different cases. It is, however, contended by the author of the "Landed Property of England," that the plan and formation of all *public* roads should be the same; every public lane, or other scite of a public road, he conceives, ought, where the width and other circumstances will permit, to be divided into three travelling lines, namely: 1. A middle road of hard materials, for carriages and horses, in winter and wet seasons: 2. A soft road, formed with the natural materials of the scite, to be used in dry weather, to save the unnecessary wear of the hard road, and to favour the feet of travelling animals; as well as for the safety, ease, and pleasantness of travelling in the summer season: and 3. A commodious path, for the use of foot passengers, at all seasons. But in these cases, he thinks, modern practice has simplified too much. Instead of these three requisites of a public road, we generally find a parliamentary or turnpike road (away from the environs of great towns), consisting, simply, of one uniform broadway of hard materials; upon which horses stumble, and carriages jolt, the year round: while travellers on foot are seen wading to their ankles in

mud, or in dust, according to the state of the wind and weather. His notion of what the nature of a public road ought to be, is, that within the fences of a lane or road there should be a raised foot-path, a convex hard road, a soft summer road, and channels to carry off the water collected by the carriage roads; the foot-path being cut across, in proper places, to permit the water, which falls on that side of the middle road, to pass off freely into the ditch at that side, as well as to prevent horsemen from riding along the path; the opposite hedge-bank being perforated, to let off, into the other drain on the contrary side, the waters which may collect on that side of the lane or road.

And in regard to *private* roads it is contended, that where they are much used, as in such as lead from a village or other place to a public road, they should have a double carriage path, so that carriages may any where pass each other. But that for such as lead merely to a farm-house or a hamlet, a single line sufficiently wide to let a single or saddle horse pass a carriage with occasional dilations for carriages to pass in, are only in general requisite.

*Form of Roads.*—Further, in regard to the most appropriate form of roads, there has been a great difference of opinion among the persons engaged in this sort of work, some contending in favour of the *convex* form, while others are inclined to think the *concave* shape preferable in many cases; and still others, that they should be either made perfectly flat from one side to the other, with inclined planes longitudinally, or be *wholly flat* in every direction. But experience fully shews, that some degree of the convex form is necessary in almost every case, in order that the wetness and moisture may be discharged with greater facility, and of course the roads be preserved in a more dry state. And in speaking of this form of road, Mr. Beaton observes, that the rise in the middle is more or less according to the fancy or whim of the makers, but in general it is a great deal too much. This form is adopted on the idea, that whatever wet falls upon the road will run off towards the sides into drains made there for the purpose of receiving it. If the roads were a perfect smooth hard surface, this theory would, no doubt, he thinks, hold good; but in practice it is found not to be the case, for the wheels of carriages occasion so many ruts, and such a roughness on the surface of the roads in general, that little or no water can run towards the side-drains, however convex the road may be. It consequently lodges in those ruts, and every succeeding carriage, he thinks, the more easily makes them deeper, and works the water and materials together in such a manner, as very soon to render the road extremely disagreeable. This frequently happens, he asserts, even on roads that have been made most inconveniently convex, for the very purpose of keeping them dry; consequently, the convexity of a road has not the desired effect of preventing water lodging upon the surface. Besides, it is, he conceives, extremely inconvenient for all wheel carriages, and destructive to the road itself, by making the loading rest unequally upon the wheels, unless when going on the very middle of the road, for the lowest wheel will always bear the greatest part of the burden, and therefore will injure the road the more in proportion. If a cart or any carriage with two wheels is loaded, we will suppose, with two tons weight; when that cart is upon a level from side to side, the load is equally divided, and each wheel sustains the weight of one ton; but if that cart is going on the side of a convex road, there will perhaps be the weight of a ton and a half upon one wheel, and only half a ton upon the other, consequently the lower wheel, in this case, will do the road as much injury, as if the cart were loaded

with three tons upon a level, instead of two upon such a declivity. The proportion of weight upon each wheel, according to the declivity, will depend on the nature of the loading of the cart, for the higher the centre of gravity of the load is, the greater will that weight be on the lower wheel on the same declivity; and therefore a cart loaded with hay, straw, or wool, or any other bulky commodity, will be more injurious to a convex road, unless when on the middle of it, than the same cart loaded with the same weight of stone, lead, or iron, or any other weighty commodity which lies low in a cart: and nothing can be more injurious on such roads, than a stage-coach loaded with outside passengers. But the destructive consequences of allowing carriages to heel much on any sort of road are even visible, though in a small degree, he supposes, from the effect produced by a wheel going over a stone, or any hard substance lying in one of the tracks or ruts, in which case there will soon be a deep hole formed by the wheel in the other track, directly opposite to that stone or substance which raised the other wheel. Every precaution ought, therefore, to be used to prevent carriages heeling to one side on any part of a road. And he suggests, that the inconvenience, and in many cases the danger, of going on either side of a convex road, makes all waggoners, carters, coachmen, &c. keep always on the middle, by which, on such roads, there is seldom any other part used by wheel carriages, however wide the road may be; consequently, by the carriages being always confined to the same track, that part of the road soon gets out of repair, and requires a constant outlay of money to keep it in proper order or condition for being travelled upon. It is also added, that the method of forming and making the convex roads, in the first instance, appears to him very absurd. He supposes, that before any hard materials are laid on, the road is generally formed in somewhat a hollow manner, rounded below, in which there are drains, or ditches, on each side: also the footways or horse roads when made high enough. These are also sometimes called the summer roads, on account, he supposes, of that being the only season they can in general be travelled upon. The road forms a convex line, about ten or twelve inches lower at the sides of it than the footway and summer road. After being thus formed and prepared, the hard materials, mostly consisting of broken stones, are laid on, which, it is supposed, will fill up that space which is the hollow in a convex line, and when finished, the whole surface, from one side to the other, forms one convexity; the footways or horse roads being made a continuation of the same curve. And this is still with the idea, that all the water that falls on the road will run into the drains on each side. But let any person, in wet weather, take a view of a road thus formed, and he will find, that, in general, however great the convexity may be, the water will stand in every rut and every impression made upon it, especially if the road has been long travelled upon; that the stones on the surface are pulverized by heavy wheel carriages, and the wet earth from below worked up among them. Also where the road is but newly made or repaired, and the materials are sufficiently porous to let through the water, it will then lodge on the convex surface, in every impression of a stone or other uneven part, particularly at the sides, where it is dammed again by the footways, and thus the bed or foundation of the road is kept constantly moist, and of course it will very soon go out of repair. By this continual moisture the stones sink down into the soft earth, of which the bed of the road is composed, and this earth works up through the harder materials, and occasions all that dirtiness generally on the surface of roads in wet weather, although, perhaps, ten or twelve inches in thickness of those hard materials had

been at first laid over it. Sometimes, indeed, there are under-drains made through the footway, from the side parts, at every ten or fifteen yards distance, to convey the water into the ditches; but even this is not found to answer the purpose intended, for the intermediate spaces soon become so impervious, that the water does not pass through them to enter these drains, the wet earth being converted into a sort of puddle, resembling what is used, in aquatic works, for the purpose of preventing the moisture from penetrating through, and consequently it lodges in all the ruts and hollows on the surface, without passing off so quickly as should always be the case in such instances.

Besides this there is another manner of forming these convex roads advised in the Bedfordshire Agricultural Report, in which it is proposed to leave a hollow or vacuum, as it is called, in the middle, to deposit the hard materials in. The only difference that appears to be between this and the method described above, is, that instead of the bottom of this hollow being made convex, it is made flat, and also deeper. It is thought that this method is liable to the same objection as the former, perhaps even in a stronger degree; besides, it would require a much greater thickness of hard materials, which are very expensive, and those materials would be deepest or thickest in the middle of the road, where the wheels of carriages hardly ever go, consequently that part is not so liable to be cut up as the tracks in which wheels most generally run, and produce their greatest effects. Mr. Marshall seems, however, to think more favourably of this form of road, especially for wet weather, assuming it as a found position, that roads, in general, which are intended to be travelled in wet seasons, should be *convex or shelving*, not flat or concave. It remains to determine the proper degree of convexity of the hard line of road; from the margin of which the dry-weather line ought to shelve gently to the foot of the hedge-bank; so that carriages may pass freely, and safely, from one line to the other; and in order that the rain-water which falls on that side of the lane may find its way, easily, into the channel prepared for it, which is, he conceives, for a wet-weather road, to be regulated by a variety of circumstances: as, first, by the materials of which it is to be formed: soft materials are most liable to be worn into ruts and hollows, and require to be laid up with a quicker descent for rain-water, than hard materials, which require less elevation or rotundity of surface; and least of all a firm even pavement. Secondly, that a convex road in the face of a steep is to be laid up higher, with a given material, than one on more level ground, on which rain-water has no other tendency than to the sides; whereas in the face of a steep, it may have an equal or greater tendency along the line of road; and is liable to be caught by the slightest impressions of wheels; and thus to wear channels, as may too often be seen, from the top to the bottom of the hill. Even where the surface of the road is perfectly smooth, it may have twice the distance to run, before it reach the outer margin, that it has on a level. And thirdly, that the degree of convexity is to be determined, in part, by the width of the road; the materials and descent being equal. A wide road requires to be formed with greater sideway descent than a narrower one; which more readily frees itself from rain-water, inasmuch as the distance is shorter from the crown to the outskirts of the road in such instances.

But that the freeing of a road from rain-water is not the only object to be kept in view, with regard to its convexity: the ease and safety of carriages, and particularly those of burden, whose loads, being of light materials, are laid up high, require to be considered. A carriage moves most freely, and with the least exertion of draft, when the load

lies evenly upon the wheels on either side. In proportion as the weight is thrown on one side or the other, the resistance is increased; especially on the road which is liable to impression. Hence the inconvenience of a highly convex road in the face of a steep; and hence the utility of breaks in long ascents, or such roads as are formed in hilly situations.

In fact, he conceives it evident in respect to convexity, that every part of a road should be equally and duly convex, —should be equally safe and easy for carriages of every description; otherwise it becomes partially worn; the more level parts only are used; the steeper being in a degree useless. Hence a road of even and due convexity is not only easy and safe, but may be formed of a narrower width, than one whose steep sides are neither easy nor safe to be travelled; and whose crown, only, is in use for passing upon. And on measuring different passages of roads which appeared to lie in the most desirable form, and taking their convexity, or the elevation of the crown or middle of the road above the base line, he has found that roads of twenty feet in width rise about ten inches: namely, one inch in every foot, on either side. And he is of opinion that this result may be taken as a general guide in forming roads: this middle degree of convexity being liable to be altered according to the width of the road, the nature of the materials, and other circumstances which have been stated already.

And concerning the second or concave form of roads, Mr. Beaton thinks that it is quite the reverse of the common form, being lowest in the middle, where other roads are generally made highest. By differing so widely from the common practice, and the general opinion of road makers, one would at first be almost inclined to suppose, that so singular a practice in forming roads could only proceed from a desire or propensity to differ from the rest of mankind: but when we are told that the late celebrated and ingenious Mr. Bakewell was an advocate for this form; that the road by his farm of Dishly, and that through Mesham, in the same county, are both upon this principle, and in much better order than the roads found about them; likewise that the road through Bredon, made under the direction of Mr. Wilkes, is of the same form, and is said to be better now than ever remembered before, and kept in order at much less expence:—when we consider these well authenticated facts, supported by such respectable evidence, we naturally conclude that the reasons for adopting this uncommon form of road, are founded on something more substantial than mere whim and caprice; and consequently deserve to be more fully investigated. This writer states, that he has not been able to learn the manner of forming these kinds of roads before the hard materials are laid on, but, when completed, he understands the form is something similar to that of a paved street, with a drain for the water in the middle. The whole width of the road is divided into three equal parts, or nearly so. The sides are made quite flat. The middle division has a gradual but small descent, or concavity, from each side to the middle part, which is the middle of the road. This concavity has also a small descent lengthways, made on purpose, if not declining naturally, sufficient to carry off the water to proper outlets. In the middle division the best and hardest materials are laid. The direction of Mr. Wilkes, as stated in an ingenious paper, in the first volume of Communications to the Board of Agriculture, is, that when the fall is one foot in 150 or 200 feet forward, the fall from the sides towards the middle ought to be 15 inches in 20 feet. When one foot in 100 to 150, to be 12 inches. One foot in 30 or less, to be even the whole breadth.

Where the width of a road is 60 feet, one foot of fall to each 40 feet in length of the road. Twenty feet from the sides towards the middle, to have nine inches of fall.

The inner 20 feet to be flat.

And Mr. Bakewell's idea, he is informed, was, that water, where it can conveniently be applied, should frequently be let run upon this concave part, in order to wash it quite clean; for it is always observed, where a small stream of water comes upon a road, that part, if the bottom is good, is generally firmest, and hardly ever gives way. To have a command of water, therefore, to flood the road at pleasure, he thought would be of great advantage in keeping it in order. And the other useful properties attending a road of this form are the following: There are three parts of it on which wheel carriages may go, without heeling to either side; on the side divisions, and also on the middle division, when the horses walk in the lowest part. This is certainly a material advantage, being much more easy for the horses and less injurious to the road. By carriages using indiscriminately these three tracks, all parts of the road will wear more equally and for a greater length of time; whereas in the convex roads, there being only one part, namely, the middle, on which carriages can go without heeling, that part only is most generally used, and consequently soonest gets out of repair, which is a great inconvenience in such roads.

With respect to flat roads sloping longitudinally, the advocates for them observe with good reason, that by being flat or level from side to side, the pressure of wheel carriages will be more equal, the friction less, and all parts of the road may be travelled on with the same facility; consequently it will wear more equally, be easier kept in repair, and require fewer materials for keeping it up. But notwithstanding such advantages are deserving of attention, it must seem to those unaccustomed to such a form of road, a difficult matter to keep it sufficiently dry, or free from the stagnation of water upon it. But from its having been observed that the ruts made by the wheels of carriages prevent the water running to the sides of convex roads, it is proposed that roads of this form should have in every level part gentle slopes, sufficient for water to run along, which, supposing them to be one foot in fifty, would hardly be perceptible. On these slopes, or inclined planes, the ruts made by the wheels of carriages would promote the water running off, by forming so many little channels or conductors for it to run into the lower part of these slopes, from whence it must be properly conveyed away. By this plan such roads will be much more easily kept dry than the common roads usually are or can be from the nature of their construction.

And farther, in regard to the wholly flat form of roads, the reasons given for them are nearly the same as stated in support of the last, only that as there are few parts of a country so perfectly level, for any considerable distance, that water will not run either one way or another, it is consequently unnecessary to be at the expence and trouble of forming those slopes or inclined planes recommended in the preceding form; but that proper outlets should always be kept clear at every hollow part, and if the road should in any place be quite level, a shallow cross drain, that will occasion no impediment to carriages at every 50 or 60 yards distance, or nearer, will keep the road sufficiently dry.

And it is from these statements concluded by Mr. Beaton, that the main objects sought after are, 1. To keep the road always as free from moisture as possible: and 2. To construct it in such a manner, as to render the draft or communication easiest, at the least expence. In these are

comprehended all the requisites necessary to form a complete road. To attain them in the best manner is therefore the important point. Four different methods have been stated, each of which has its supporters. The arguments in favour of each have also been shortly mentioned, which will shew that their main object is the same, unless perhaps the idea of watering the concave road may be considered a deviation from one part of the general rule: but as that is proposed to be done only to wash the road occasionally, in case it becomes dirty or slushy, it cannot therefore be considered in that light in any respect whatever. But from these modes of constructing roads being in some measure unsatisfactory, he is induced to offer a new theory on the subject, which is founded on the knowledge of the stratified nature of the earth. It is however only given as theory, having never, he believes, been subjected to the test of actual practice. It is observed, that every person who has paid the least attention to the structure and formation of the different strata of the earth, must have seen that some of these strata are of so close a texture as to be impenetrable to moisture; others again are so porous, that water will easily run through them in any direction, till it meets with some obstacle, or finds a vent. Of the first sort some are less dense, and of the latter more less porous than others, consequently as they partake more or less of these qualities, the water or moisture will the more or less quickly penetrate through them. But in order to shew this more clearly, and apply the principle to the construction of roads, he supposes the section of a hill or eminence composed of a number of strata. If the upper stratum or surface soil is of a porous nature, it is evident that any water which falls upon it, will penetrate through to the stratum below, where, if it cannot go farther, it will glide along the surface till it finds a vent at the bottom of the hill; if the second stratum is hollow, and continues on towards any depression in it, the water will lodge in that hollow, and form a sort of pool or bog, as is sometimes observed on the tops of hills; but if in this hollow place there is a communication with the porous stratum, no water will lodge there, but it will penetrate through and glide along the upper part of the dense stratum below, till it finds a vent on the side or at the bottom of the hill, as before. And by the above it will also appear, that if the uppermost stratum is of a close texture or clay, any water falling upon it will not only lodge in the large hollow, but in the smaller ones, and in all the other irregularities or concavities that may happen to be upon the surface. Hence, also, it is evident that in order to keep dry the surface of any such piece of ground, it matters not of what shape or form that surface is, or whether it is convex or flat, provided there is a communication with some under stratum, sufficiently porous to carry off the water below; but it is of some consequence the form of the upper part of that stratum upon which the water is to run, for the smoother it is, the water will of course the more easily flow away, and be discharged from it.

It is easy, it is supposed, to apply these principles in the forming of roads in the following way: when a new road is to be formed, let it be done in the first instance nearly in the usual manner, with such materials as are on the spot, and the nearer the quality of these approaches to *clay*, so much the better. Instead, however, of forming it convex, as is generally done, let the lines on either side from the middle be quite straight, and meet in an angle or ridge at that part or the middle of the road, having a slope from thence to each side, of about an inch in a foot. There are to be made small drains for the more easily conducting away the water that may be collected at those places. The road, being thus

formed, must be allowed to harden and settle for some time before any other materials are laid on, great care being taken, while in that state, to let no carriages or cattle upon it, and it should be rolled with a long wooden roller, that will reach at once from each of the sides to the middle. This roller should be loaded with a box of stones to make it sufficiently heavy, and that it may be the more portable when that box is taken off; and it may be so contrived, that by changing the horses from one side to the other, there will be no occasion to turn the roller, in order to make it roll the same space over again. Being rolled in this manner, will consolidate the materials composing the ridge of road, and prepare it for receiving those to come afterwards, for it is a most absurd practice to lay hard materials in the common way upon this first form or basis of a road, before it is sufficiently firm to bear them. When thus formed and properly settled, the next step to be taken is to imitate the works of nature in dry soils as nearly as possible, by forming a stratum penetrable by water, composed either of sand or sandy gravel, or any other substance easiest to be got, that is sufficiently porous to admit water to pass through it. This stratum should be laid quite level, and extending from one side of the road to the other, filling up the small drains also on the sides. Over this are to be laid the best materials that can be got for completing the road, consisting either of stones broken very small, or of the best gravel. This coat of hard materials need not exceed above six or seven inches in thickness, which being much less than is commonly used, will be a considerable saving; and it may even still be less, if the directions hereafter given are strictly attended to. If this covering consists of broken stones, they should afterwards be laid over with sand or fine gravel, when easily procured, so as to fill up all the cavities betwixt them. The sand or rubbish from a freestone quarry is excellent for this purpose, providing there is no mixture of earth in it, which should be carefully guarded against in every step taken after the road is first formed. These finishing materials being properly laid on and smoothed with a rake, the whole should now, before any carriages or horses are admitted upon it, be well rolled with a heavy iron roller, divided in three parts for the purpose, the two hind divisions of the roller being large, the front or middle division smaller, to the framing of which the shafts are fixed, and so contrived, that it turns in the manner of the fore-wheels of a waggon; there is a box for holding stones to increase the weight when necessary; but in adding this weight, it must be observed to lay about two-thirds of it over the two large parts, and only one-third over the other, otherwise the pressure will not be equal. Iron rollers are sometimes made in three parts, as above, but being all in a line, and close together, they are apt to be choaked by gravel and small stones, which cannot happen in the construction here recommended. It is contended, that if such a roller were generally used upon roads, especially when newly made, it would save a great deal of expence in repairing them; for it cannot be expected that any new road will immediately bear wheel-carriages, or continue long in repair, when composed entirely of loose materials, without the smallest pains being taken to consolidate them together. Frequent and heavy rolling would therefore produce the most beneficial effects, and would tend very much to keep the road free from deep ruts and holes; besides, there is nothing could contribute more effectually to promote and preserve firmness and solidity, two qualities without which it is impossible any road can, with propriety, be called a good one, or have the necessary degree of solidity and firmness.

The advantages that would result from this mode of construction

struction would be various : by being level on the surface, every part of it is equally commodious for carriages, consequently it will all be equally travelled upon, and the deep ruts so frequent in other roads, will almost entirely be prevented. It will therefore be much easier kept in repair, and, if properly managed at first, will be made at less expence than the common roads, especially in a sandy soil, or where sand or gravel is easily procured. The draft will be much easier on such a road. And one very important advantage is, by having an under-stratum through which the water can penetrate, and the cavities among the harder materials being filled with the same porous substance, no water can ever lodge on the surface, nor can it ever become so dirty as other roads are in wet weather ; all the water that falls on the surface, unless perhaps in very heavy rains, being conducted away underneath and in every part. And it may be added, that from the small drains on each side of the road, cross-drains should be carried through the fences, provided the level of the ground will admit of it, at the distance of every ten or fifteen yards. These cross-drains may be made of wood, with about an inch bore, or of stone, if preferred.

It would be of great advantage to this sort of road, as well as to every other road where the ground is inclosed on each side, that the fences should be sunk towards the fields, and the water be conducted through to these sunk fences, instead of the common method of leaving large open ditches and drains on each side of the road. It must also be particularly attended to, that on all sloping roads on a declivity, where the water is apt in heavy rains to run upon the surface, or at the sides, that it ought never to be allowed to run in the same direction more than ten or fifteen yards, but at that distance to be conducted away to a side into the main drains. It will then do little or no harm, as it can never increase beyond a very weak stream ; but if it is allowed to run one hundred or two hundred yards, it will probably be increased to such a size before it reaches the bottom, that it will wash away a great deal of the materials, and may besides very much injure the road or fences on each side of it, which would be highly disadvantageous in many respects. Besides, it is suggested, that a road formed on this plan need not be quite so wide as roads in general are made, for the whole surface of it will be in use from one side to the other, and therefore from twenty to twenty-four feet wide is quite sufficient, unless near populous towns or extensive works, where great numbers of carts or waggons are employed. And in the interior parts of the country, twenty feet in width will answer every purpose required. He has observed in several places, where the roads have not been above eighteen or twenty feet wide, and properly made from side to side, that they were in much better condition than the neighbouring roads, from thirty to forty or fifty feet wide. On these wide roads, formed in the usual way, there is seldom more than eight or ten feet in the middle of them generally made use of ; the remainder one on each side being occupied by heaps of stones, scrapings, and other rubbish, which, although they may partly be of use sometimes in repairing the roads, ought on no pretence to be allowed at all times, or at any time, to lie there ; such rubbish being not only disgraceful on the sides of a public highway, but even dangerous, particularly in the dark, for either carriages or horses ; besides having various other disadvantages arising from the growth of weeds, and the dissemination of their seeds.

But in respect to the most proper and best form of the roadway of narrow lanes, as those leading from village to village, in reclusé situations ; where bridle roads, or packways, have been so far opened as to admit carriages ; or

though the whole width of the lane may not be more than eight or ten feet, it is remarked by the author of the treatise on "Landed Property," that on such a narrow space, a whole barrel, or convex road, cannot easily be kept up. If raised, it presently wears into a middle track, and two wheel-ruts, with foul drains on either side of them ; and becomes, in wet weather, a dirty trough, which is unfit for either carriages or horses, and in which a foot passenger has not where to set his foot. But that provided such a lane be thrown into a shelving form, resembling half a barrelled or convex road, a greater width of travelling road for carriages and horses will be obtained ; ruts will not be so liable to be formed ; the whole of the water of rains will be thrown on one side ; while the other will afford a comfortable walking path at all seasons. And this, it is added, is now no longer merely a probable, but a tried improvement. Lanes, ten, twelve, or more feet wide, have been strikingly improved by it. And it is further suggested, that when water, in a wet season, is apt to ooze out of the banks on the upper side of the lane, a narrow channel is to be cut, to prevent its overflowing the road : or, in forming the bed of the road, the inclination may in some cases be reversed ; so as to throw the drain on that side of the lane from whence the spring water issues : thus the same drain will serve for the spring and the rain-waters. And it is added, in regard to this semi-convex form of road, that it is applicable, not only to narrow lanes, but to the sides of hills ; where the road, as it generally ought, is conducted sidelong, not directly, up the slope. By this form of the road, the whole of the water which falls upon it will be got rid of, without inconveniency or expence. And the bed of the road, for this purpose, may be made narrower than for a full convex road ; a circumstance which, in some cases, may become a saving of much expence. The upper side of a road in this form being nearly level, and firm to the foot of the steep, would be chosen by ascending carriages ; while the lower side would acquire a looseness of surface, and be used by laden carriages going downward ; and while a raised foot-path, on the lower margin, would be a secure guard, and a relief to the apprehensions of timorous travellers.

But in relation to the width of public roads where a bank is given, it should be regulated, Mr. Marshall says, by their publicity, as it is compound folly to make a road wider than its use demands. He supposes that there are few roads, even near populous towns, that require a greater width than about thirty-three feet. But every public road, under common circumstances, should have a line which is travelable at any season, and of ample width to permit two carriages to pass each other with freedom and safety. This ample width let us set down as one statute pole. In deep clayey districts, where hard materials are difficult to be procured, a single road, of half a pole in breadth, with dilations at proper distances, to let carriages pass each other, may, in many reclusé situations, be advisable. This regards the breadth of the winter road, for carriages and animals of burden. But that the width of a public lane requires a more enlarged view. On the plan offered, it is to contain, not only a wet-weather road, for carriages and horses ; but a summer road, and driftway ; as well as a foot-path, which may be used in any season. He observes, that in many parts of the greatest public roads across the kingdom, the lane is not more than twenty feet wide. But this being filled with hard materials, from hedge-bank to hedge-bank, carriages alone seldom find any inconveniency in these narrow parts. But where carriages, and large droves of cattle or sheep meet in them, stoppages are unavoidable, and great inconveniency is of course sustained.

And it is thought, that the width of the *driftway* ought, like that of the hard materials, to be guided by the publicity of the given road. In a great public road, it should certainly be wide enough to let two carriages pass each other, or one pole in width. But in one of less publicity, or where the existing lane will not admit of that width, a single carriage path may suffice; as this being a continuance of the width of the hard road, no difficulty in passing can be experienced, it is supposed, from it.

But the width of the *foot-path* and the ditch may vary from half a pole to ten feet.

It is therefore concluded, that on these premises, the width of the lane of a great public road, near a populous trading place, ought to be fifty-nine feet and a half; and that of a common market-road, thirty-three feet. And these widths, without any previous intention, come out nearly the same as those directed by act of parliament, for the lanes of turnpike roads and highways. A great error in the act, however, is, that the lanes of all turnpike roads, shall be sixty feet wide: thus incurring a serious waste of land; and creating great nuisances; which green lanes ever are to the occupiers of adjoining lands. He from this suggests, that where existing lanes are wider than all the desired conveniences require, slips should be sold off their sides, and be laid to cottages, or to the adjoining inclosures; having recesses here and there, in which to lodge materials. It has long appeared to his mind an evident position, that every part of a public lane should be used; and consequently that no part of it ought to be a nursery for weeds, or an unprofitable common pasture for starving stock. Still he remarks, that a wide lane has its advantages; especially in a low close situation. It gives freer admission to the sun and air than a narrow lane, and the road dries more quickly. And further, that by permitting a more forcible current of wind, the pulverized materials, or dirt of the road is, in dry seasons, carried off in the state of dust; leaving the useful materials undisturbed. And it is highly proper to place the principal line of road in the midway of the lane, that it may be the most effectually exposed to the agency of the sun and wind.

Mr. Beatson even suspects, that, in the whole kingdom, thousands of acres of fertile lands are lost to the public, merely by making the roads so much wider than there is any necessity for. In the vicinity of large towns, they should have an ample width, as 30 or 40 feet; or, in some cases, considerably more, as near the metropolis. But the practice of making them 40 or 50 feet wide, as is sometimes the case, through a thinly inhabited part of the country, or near the most pitiful villages, where even 20 feet would be sufficient, is, he contends, a mere waste of ground for no purpose, and occasions a very great additional expence in making such roads, which certainly might be avoided. Supposing the medium necessary width of road to be 7 yards, or 21 feet, and that the medium width now made is 11 yards, or 33 feet; this is, upon that supposition, 4 yards wider than is necessary; which, in every mile, is a loss of 1 acre 1 rood and 2 perches: and supposing there are 5000 miles of such roads in the whole kingdom, there is a loss of more than 6300 acres, which, if estimated the same as the improved value of the waste lands, at 27s. *per* acre, and at 30 years' purchase, would produce 255,150*l.*; a sum which, if laid out in improving the roads, and making easy communications through different parts of the kingdom, would be of the greatest public advantage. And it is evident, that where they have the width stated as necessary by the first of the above writers, the loss sustained in this way must be still greatly more considerable.

Mr. Marshall thinks, that in the operation of forming roads of the public kind, the first business of the road-surveyor is to examine the lane, or other site of the intended road, in every part, to ascertain whether offensive waters lodge beneath it, and whether quicksands or land-springs break out in a wet season, in which this examination is requisite to be made. If defects of this kind be found, effectual subdrains are to be run up to them from the ditches or side-drains of the lane, or other site. And that the next operation is to adjust the surface of the site; to strike off the protuberances, and fill up the hollow parts; and thus, in ordinary cases, to mould it to the first proper form, or according to some of the other forms that have been mentioned; the foot-path and the higher side of the soft road being raised with the earth which is required to be taken off the bed of the hard road, whose base or foundation ought to be formed with peculiar care. Every part is required to be firm and found; dry earth or hard materials being rammed into every hollow and yielding part. It is suggested that the first form is adapted to firm binding materials; to such as acquire, by wear, a repellent surface, and shoot off the waters that fall upon it; not to those which are loose and incohesive, yielding to pressure, absorbing rain-waters, and conveying them down to the base or bed of the road. These require a flat or a convex bed, free from obstructions on either side, so that the absorbed waters may effect their escape at the base. And that on this firm and level bed the largest of the hard materials are to be laid; next, those which are more finely and evenly broken; and, lastly, a covering of still finer materials: to assist the roller in giving sufficient firmness to the surface, and to render it immediately capable of being travelled upon.

But in regard to the proper materials for constructing roads with, Mr. Marshall thinks that although every district may be said to have its own material, and often without choice or alternative, yet there may be instances in which useful materials are overlooked or disregarded. And that in some parts, particularly in Lancashire, large paving stones are in common use; some of the more public roads being rough pavements, resembling the streets of ill-paved towns. But that in the northern, and some of the midland provinces, broken quarry stones are the ordinary road material; and that, taking the kingdom at large, they are the most common material. But in the southern and western counties, flints and other hard field stones, gathered off ley grounds, are in common use; and in the neighbourhood of the metropolis, and in other parts of the kingdom, sharp flinty gravel is a favourite and valuable material. In many parts of England, smooth, water-worn, pebbly gravel, collected on the sea-beach, and in river beds, is used; and if the pebbles are of a hard texture, and be properly broken, to make them bind, or unite firmly together, a good road may be made of this material. In some cases, sand and silt, or fine sea-sand, have been employed with success.

It is likewise added, that the artificial materials of roads, which he has met with, in quantity, are the dross and cinders of iron and copper works; and burnt clay, (burnt as bricks in heaps,) which in a clayey district, destitute of other materials, and where fuel is cheap, may be found a valuable substance for the purpose. It is suggested by Mr. Beatson, that in a sandy soil the roads may be made on the new construction, he has already recommended, with the greatest ease. In such a soil, there will be nothing more to do than to level the surface properly, fill up all the hollow parts, roll it well with the long wooden roller, and lay on the materials intended to finish it with, in the manner di-

rected, and then roll it with the heavy roller, as has been advised above.

But in cases where the soil consists entirely of a deep loose sand, the best and easiest way to make a lasting road is, to form it to the width intended for the hard materials, and then to let a channel be dug at least 18 inches in depth, and about the same width: let these be again filled, and firmly built up with strong turf or clay, or any other solid substance that will prevent the materials to be laid on the road from spreading to either side; openings being left at every 10 or 15 yards, to let the water that falls on the middle part of the road more easily through. Where the form of the ground requires making up, a little wall of the same nature, instead of digging a channel, may be built on each side, nearly as high as the surface of the road is intended to be. These will prevent the hard materials laid on from spreading, which is the principal cause of roads made in such soils giving way in so short a time; and these materials will not be so liable to sink into the sand, if it is properly rolled before they are laid on, as well as at different periods after it is finished. And if there be a fence on each side of the road, and materials can be spared to cover it from side to side, there will be the less occasion for the little walls; as these are only intended to keep the hard materials within the bounds prescribed, in case it is not judged proper to lay them the whole breadth of the road. Where, however, those walls are thought requisite, the spaces, by being covered with a little gravel or freestone-sand, will make very good foot-ways or horse-roads; but in a road finished in this way, there will be no occasion for horse-roads distinct from the main road, as the whole, if kept in proper order, will, he supposes, be sufficiently smooth and safe for horses, or even foot passengers, to go upon at any time. In speaking of the making of roads through a clayey soil, it is remarked that those formed in such districts are in common the most unpleasant of any, chiefly on account of proper precautions not being taken to prevent the water lodging on the surface; sometimes, perhaps, owing to a want of proper materials, such as stones or gravel: but he has often seen the very worst of clay roads, even where no such excuse could be given. And that it seems hardly ever to have occurred to those who had the direction of such roads, that sand, properly applied, would in a great measure remedy all the defects complained of; and there are few parts of a country where sand of some sort, or freestone-rock, or sandy gravel, may not be obtained by some means. In certain situations it may, no doubt, be more expensive and difficult to procure such materials than in others; but these are local advantages, which road-makers must lay their account with. But the excessive inconvenience of bad roads, the expence occasioned by the tear and wear of wheel-carriages and harness, the risk of dislocating the limbs of horses, together with many other disadvantages, ought to stimulate all concerned to exert their utmost endeavours to make roads good, and easily passable, be the difficulties what they may, that stand in the way of them.

It is hinted, that in such places as where no hard materials can be got, if the road were formed nearly in the same manner as that first noticed, the evils complained of might probably soon be remedied. The clay should be excavated, so as to form a ridge in the bottom of the excavation. There should be small openings or drains at every 10 or 15 yards, or at every hollow place, to conduct away the moisture into the main drains. If this excavation is then filled with sand, or any other porous matter easiest to be got, and finished as formerly directed, there is no doubt but the road would soon become as good as could be wished

for. Something similar to this he has known put in practice by a very ingenious gentleman in Cheshire, on whose estate, being a strong clay soil, the roads were so excessively bad as hardly to be passable. He dug away the surface of the road to the depth of 12 or 14 inches, and having the command of plenty of sand, he filled up the excavation therewith, and covered the whole with gravel; by which means he has now made, so far as completed in this manner, as pleasant a road as one could wish to travel on. He is not certain if he left the bottom of the excavation with a ridge in the middle, as here directed; but he is clear this would be an advantage, as well as the outlets at certain distances, to let away the water.

And in constructing roads through boggy or morassy soils, it is advised, after proper steps have been taken, to drain off as much of the water as possible, by deep ditches or drains within the fences, if inclosed, or intended to be inclosed, on each side. These drains should be cast at least a twelvemonth before any thing else is done towards making the road; for if the place is very boggy, it will be found to subside considerably after the water is drained away; and some parts will subside more than others, in proportion to the depth of the mossy soil, and to the quantity of water lodged there. Those parts will, therefore, be the better seen the second season than the first. All hollows or irregularities should then be filled up and levelled, either by taking from the heights and filling up the hollows, or by some other proper materials nearest at hand. In either case, the surface sods should, with a push-plough or paring spade, be carefully pared off the heights to be lowered, and also off the hollows to be filled up. These sods should be laid aside, till those places are brought to their proper level, and should then be laid on again. This will make the whole surface of an uniform toughness, which would not be the case where the sods are not laid on in this way. After this has been done, the breadth of the intended part for receiving the hard materials should be marked off; then let that part be covered with sand, or such porous substance, as before recommended, to the thickness of at least 10 or 12 inches. Then roll this, and finish it as already directed; and there is no doubt but a road made in this manner may be as good through a moss as in any other situation. This he speaks of from experience, having seen the most pleasant roads made in this manner, through mosses formerly thought impassable. When the moss is too soft to admit horses upon it, the sandy stratum may be rolled by men, the weight of the roller being regulated by the stone box, according to their strength. Sometimes the rolling is altogether omitted; but it is much better to roll, when practicable. It is added, that there are other methods of making roads through mosses; as by laying a foundation of broom, furze, or heath, and then the hard materials above them. But sand is greatly preferable, where it can easily be got, and when the track of the road is properly drained, as it always ought to be, before any thing is laid upon it with a view of making a road. These principles and directions are, it is said, equally applicable on all other sorts of soil, with trifling variations, according to the peculiar circumstances of the cases.

And it is supposed, that in the above cases the roads were formed where the scite or track was nearly level from one side to the other; but there are other situations, such as when cut or formed on the sides of hills, where some other precautions become necessary to be attended to. In these cases it is observed, that in making them it frequently happens that the excavation affords a sufficient quantity of materials for the purpose; and the part cut out

of the solid very rarely requires any covering laid upon it. This, however, depends on the nature of the soil. If the whole breadth of the road is formed from the solid, and that is sufficiently hard, no extraneous materials will be necessary; but if the soil is a compound of clay, or of a soft nature, the above rules and regulations must be had recourse to. And that where the parts are made up from the excavation, they ought to be formed considerably higher at first than the other parts, as they will naturally subside for some time afterwards, and the hard materials should not be laid on till they have sufficient time for that purpose, which may be greatly expedited by rolling; and it should be observed, that it is much better to be obliged to lower those parts to their proper level before the materials are laid on, than to be under the necessity of making up any of them at the time. And further, that where the hill is of a considerable height above the road, a good deal of water will sometimes come down. In this case it is in general better to intercept that water at some little distance from the side of the road, than to allow it to run down the face of the bank. If allowed to run down this face, it will very soon moulder it away, especially in frosty weather, and will always choke up any drain that may be made, whether covered or open; for if covered, the earth that moulders down will in a short time become so close, that water will not get through it to the drain before it runs off upon the road; and if open, it would be extremely difficult and troublesome to keep it clear. In this case, by intercepting it about four or six feet from the brink, and conducting it away to the most convenient outlet, it would be much easier to keep the road dry. If the face of the bank be irregular, the water may still be conducted away, by making the drain recede from the brink at such places, and keeping the course always at a proper level, or it might, he supposes, be let off at every hollow place by small recesses faced up with stone, or by wooden spouts sunk upright in the bank at every such hollow; to conduct the water from the upper drain to a cross covered drain below the road, by which it may be carried away at the lower side, without any injury being done to the road. And it is advised, that in the forming and making of these, as well as all other roads, the preventing of any water running on them, except what falls from the clouds, should carefully be attended to. Where this cannot easily be done, and where it is necessary to allow a stream to run along the side of a road, the drains or ditches which, as before observed, should be within the fences, should be made of a proper size accordingly, as the small drains filled with sand or gravel, as already recommended, are only meant for such roads as can have no extra water coming upon them in this way.

But in respect to *private* roads, the nature and manner of laying them out has been already noticed. And in respect to the method of forming them, Mr. Marshall says, it is the same where strong cohesive binding materials are made use of, whether in a lane, or across open ground. The mode he advises is to form a receptacle for such hard materials, twelve or more inches deep; either by digging to this depth beneath the natural surface, and carrying off the excavated soil; or to half the depth, disposing of the soil raised in the operation on each side of the receptacle; so as to elevate the general surface of the road above that of the adjacent ground. And in this receptacle deposit the materials; leaving the surface either in a convex or a semi-convex form, as the turn of the surface of the ground to be travelled over may direct: the margin or margins of the road, at which the rain-water is to be collected, being

left a few inches beneath the adjoining sward. But that in forming roads of every description with sand, loose gravel, or other incohesive absorbent materials, which imbibe the rain-waters that fall on them, a receptacle of that kind is altogether improper. Such materials ought to be laid on a level or an elevated surface; and a shallow drain to be open on either side, for the absorbent waters to filter into; thus preventing a furcharge, and freeing the surface entirely from collected moisture, which would be highly injurious to it. And it is here added, that the surface of a road which is formed of well-broken stones, binding gravel, or other firmly cohesive materials, and which is much used, presently becomes repellent of the water which falls upon it; no matter as to the basis on which they are deposited; provided it is found and firm enough to support them. And that where the situation is low and the land of a moist retentive nature, a deep drain on one or on each side may be proper to give due firmness and stability to the base. Such drain, however, is not to be sunk close along the margin of the hard materials, to deter horsemen and carriage-drivers from coming near it, but a few feet distant from it; so that every inch of the hard road may be used with equal pleasure and safety, and a commodious driving and walking path be formed between the road and the drain; proper channels being cut across it, in order that it may be kept properly dry. And further that in a dry situation, as across a gravelly or stony height, little more is frequently required than to remove the surface mould, and lay bare the rock or the bed of gravel beneath it; and then to give the indurate base a round or a shelving form, as the lying of the ground may require. In this way a travelling road may be made, and kept up at one-tenth of the expence incurred by the ordinary practice in this case; which is to gather up the surface soil into a ridge, and on this soft spongy bed to lay coat after coat of some hard materials, fetched perhaps from a distance! at much expence for the purpose.

But in addition to the above sorts of roads there are still others, which require some art to form and keep them up in particular situations; these have the denomination of carriage and horse-tracks, and are described under these different heads.

*Methods of Repairing Roads.*—It is noticed by the author of the "Landed Property of England," that this is a business that incurs a heavy expence on landed property, and of course requires the peculiar attention of the proprietors and managers of land. And in the paper mentioned above it is observed, that where the funds of the parish will admit, which would generally be a saving, that proper persons should be appointed in them, or have the charge of a certain extent of road to see where any part is giving way or getting out of order, and to direct their immediate repairs. Also to take care that no water stands in the hollows or ruts upon them. And, that the summer season is the best not only for making, but for repairing roads, nor ought they on any account to be touched in winter, unless to give a temporary aid to some sudden breach that is perhaps almost impassable, or to let off any standing water. Yet nothing is more common than to see a number of labourers employed on the highways in winter, when the days are short, and but a few hours labour can be obtained of them. Indeed so little attention is there often paid to repairing the highways, that sometimes old infirm people are employed for the purpose, as if repairing roads were a sort of trifling bye job, merely for the employment of paupers, or lame, miserable objects, who can get no other means of subsistence. And Mr.

Marshall thinks, that in this sort of work, the best service of the surveyor is to keep their surfaces smooth and even; so that rain-water may find a free and ready passage to its proper drain. Ruts and hollow parts are to be filled up, level, or even with the general surface, as often as they are formed, and perfectly free from water. This attention is more especially requisite to a new made road, whose bed and foundation are not yet fully confirmed. But in every case, and at all times, a solicitous regard is due to this most important, yet most neglected part of road surveying. Much expence of materials and labour may thereby be saved, and the great end of road-making be fully obtained: namely, that of rendering the road in all seasons easy, safe, and pleasant to the traveller, as well as easy in the conveyance of all sorts of articles. Besides, he conceives, that in this operation, as well as that of making new roads, very much depends on breaking the materials *evenly*. For, by doing this, the wear of the road becomes regular. Where the heads of large stones rise above the general surface, they become obstacles to carriages, and stumbling blocks to horses; beside their tending, by the jolting motion which they give to carriages, to indent the surface on either side of them, and thus to increase the roughness, and hasten the decay of the road. It is added, that by the law of gravitation and the action of wheel-carriages, a pit or hollow place in the surface of a road is made deeper every time the wheel of a carriage passes through it. The periphery of the wheel acts as a chissel, and in falling into the hollow receives an impetus or acquired force in addition to the actual weight it is loaded with; and, in addition to this, an undue proportion of the general load is, by placing it out of its upright posture, taken from the upper and thrown upon the lower wheel. Likewise hard protuberances, beside being dangerous or disagreeable to travellers, whether on horseback or in carriages, are injurious to a road, as being the causes of pits and hollow places in its surface. Every hard protuberance, as the point of a stone standing above the general surface of the road, or a large stone lying loose upon it, is productive of four impressions: namely, two, by throwing additional weight upon the opposite wheels (going both ways), and two more by the impetus or acquired force of the wheels (passing both ways) in falling on the surface of the road. He therefore considers it to be the first duty of the surveyor, not only to fill up the ruts and hollows, from time to time, but to pick out or to crush with a heavy hammer the stones, whose tops rise above the general surface; as well as to gather off those which lie loose upon the road; the latter being an operation that is readily performed, yet frequently neglected, and in some places to a shameful degree, especially in the northern parts of the island.

And in respect to the sizes most proper for road-stones it requires much latitude. Not only the intended use of the road, but the nature of the material is to be considered. A road for broad-wheeled carriages of burden, only, may be made of larger stones than one for narrow wheels. And hard stones require to be broken smaller than those which more readily wear down, and form a travelling surface. For when once the surface of the materials becomes united and cemented together, and its rock-like texture established, the stones that are crushed, and the smaller fragments which are splintered on, in wear, serve, he supposes, to incrust and bind together the stratum of stones which lie next, in succession, beneath: especially if proper attention be paid to the irregularities of wear, and to bring back the surface, wherever it is requisite, to its original evenness of convexity where that form is adopted:—so that it may, in

every part, act as an arch, and may be able to resist, with the greatest firmness, the weight with which it may be impressed. It is, however, to be observed, that, in forming and repairing roads with stones of size, a considerable share of the expence arises from the labour of reducing the materials; and, in consequence, the smaller they are broken the greater becomes the expence. This, on ordinary occasions, is a serious consideration. Hence, in constructing and repairing common roads, it is advisable, instead of reducing the surface stones to small fragments with the hammer at a great cost, to cover them with materials that are already reduced; as the rubbish of stone quarries, soft stones, or gravel, or the scrapings of the road to be repaired. Such cementing materials being washed and worked down by rains, and the action of carriages, and the feet of travelling animals, among the surface stones, assist much in binding and fixing them in a firm crust; and in making the road immediately passable by horses and light carriages; most particularly if the whole be compressed, and united together with a heavy roller (suitable to the purpose), repeatedly passed over the surface of it. And another good method of saving expence in this way, where materials are readily procured, is that of placing the coarse unbroken stones or other hard materials in the bottom part or bed of the road, covering them over with gravel, or other sorts of materials that are of a small kind. However, where the hard materials are broken down small and evenly the roads are found to wear the best.

The proper materials for repairing roads are in a great measure the same as those which are used for the making of them in the first instance. The writer of the Agricultural Report of Middlesex thinks the rounded stony materials of the nature of flint, found in gravel pits and river bottoms, are in every respect more fit for roads than any other stony matters. The materials for the support of great public roads should, it is supposed, be selected from among such stony substances as are tough as well as hard; for this purpose, hornblende is believed to be particularly suitable, to which may be added whinstone, basalts, iron-ore, and all such stones as contain iron, as well as the slag, or the refuse of furnaces. The comparative weight which stones of similar size and figure can support without being broken, is, it is imagined, the criterion by which to try them for this use.

Mr. Beaton thinks, that if the above directions were strictly attended to, and every appearance of a breach or defect in a road at once repaired, the same materials, when displaced, would very often, if properly relaid, and fit for the purpose, repair the part beginning to fail; whereas, if neglected for some time, and allowed to get much out of repair, it will probably require a considerable additional quantity of materials, and thereby occasion a great deal of expence that might have been saved. He also suggests, that during the time of hard frost, it may be very proper to drive materials, and lay them down for the purpose of being at hand to repair the roads when the season permits, but such a time is the most improper of any for applying those materials. And that in laying them down it is a very general practice to place them in small heaps along the sides of the road, and even encroaching sometimes very much upon the space allotted for travelling on. This ought on no account to be allowed (unless those materials are to be immediately used), for reasons so obvious, it is unnecessary to mention them. It would be much better to have recesses at certain convenient places, for the purpose of laying the materials in till wanted; by which means the inconveniencies attending the common way would be totally avoided;

avoided; and travellers might then, without interruption, use any part of the road they found best; and besides, there would then be less occasion for making the roads so wide as they are generally made, which would undoubtedly save a great deal of money in keeping them in repair, or proper condition.

It is stated, that rolling of roads with a heavy roller, as directed above, would be a very beneficial practice in keeping them in good repair, especially if the hard materials, that are worked out of place by the wheels of carriages, are raked in again previous to the roller passing over them. This would be an easy and expeditious operation, and if taken in proper time, would, in many cases, be all that is necessary to put the road in repair. It is, however, an implement that is very seldom made use of for this purpose by the overlookers of roads.

And the use of machinery has probably been hitherto too little attended to in the execution of this sort of work; but from the increasing price of hand-labour, it certainly at present demands the serious notice of the managers of this sort of business. For dragging over roads, when much out of repair, in order to replace the stones or gravel disturbed by wheel-carriages, a sort of harrow has been invented by Mr. Harriott of Great Stanbridge, in Essex, for which he received a premium from the Society for the Encouragement of Arts, &c. and of which he gives the following account. "Being appointed surveyor of the roads at Michaelmas, 1786, and finding them very bad, I provided a sufficient quantity of stones and gravel against the next summer, to cover the roads pretty thick; but when so done, I found the heavy loads of chalk, gravel, and corn, soon turned the stones out, and made almost as deep a rut or rake as ever. Stubbing the quarters in I found an endless job, as well as a great expence; I, therefore, contrived the road-harrow, and by the help of which I have, during the last summer, at a very trifling expence to the parish (after the ruts were again filled up with stones), kept the roads in extraordinary good condition. A man, a boy, and two horses will do three miles in length in one day, completely harrowing down the quarters, and drawing the stones together, which, by means of the mould-boards, are dropped into the ruts, far better than a man can stub them in. Now, if a man was employed to stub, he could not do it for less than a penny *per* rod, of sixteen feet and a half, (the most common is three halfpence, or two-pence *per* rod, if they stub the outside as well as the inside quarter,) which would amount to one pound six shillings and eight-pence for one mile in length, consequently to four pounds for three miles, which the road-harrow will do in one day; and for which I charge the parish for man, boy, and horses, only eight shillings." And it is further stated by him, that it does the work better, as well as cheaper; that several other parishes are using them, and he thinks the use of them will soon become general, especially where roads are mended with gravel. The head of the harrow is three feet long, from outside to outside of the bars. The bars four inches square, and the length of them five feet. The mould-boards extend eleven inches farther, which is necessary to draw the stones (which the teeth of the harrow work up to the top) nearer the middle of the road. The mould-boards are four feet two inches long, ten inches deep, and two inches thick; they are shod with a bar of iron, and lined about six inches high with an iron plate. The teeth (which should be steeled at the points) are one foot in length, from the under side of the bars to their points; they are one inch and a quarter square, and are fixed with strong nuts and screws, with collars both on the under and upper side of

the bars. The bars are made to go lengthwise instead of across, to prevent them from splitting. The harrow is drawn by two horses abreast, a boy leads the outside horse on the outer quarter, the other horse goes on the horse-path, the man steadying the harrow by the handles. Of course they take one inside, and one outside quarter as they go, and the other two quarters as they come back. And as this harrow is certified, by several people in the parish where it is used, to do more work with one man, a boy, and two horses, in one day, and in a much better manner than could be effected by twenty men in the same time in the usual way, it must certainly produce a prodigious saving both of time and money, and having been found to answer the purpose so extremely well, renders it worthy of attention by those engaged in this kind of work.

Mr. Beatson suggests, that after the use of this harrow, the heavy roller, noticed already, would have a very good effect, or there might be a roller of a lighter construction fastened behind the harrow, to roll at the same time; although the heavy roller would certainly make the best work. And likewise that other implements, nearly on the same principle, have been constructed, particularly one of which he was shewn a model by a gentleman near Chester. Its shape is in form of an isosceles triangle, which is laid upon the road, and drawn by shafts at the base. The two sides, by meeting in an angle opposite the base, are supposed to draw the loose materials towards the middle of the road. It has two small wheels near the base or front, and one at the angle in the rear, with different contrivances for fixing the whole frame higher or lower as required.

It is also suggested that a machine for the more easily breaking stones to repair roads in the common way would be of very great use, as at present this is a tedious and laborious task. Under the article MACHINE, a very ingenious contrivance for removing the mud and dirt from roads has been described. But, although several contrivances have at different times been proposed for facilitating the repair of roads, and lessening the expence, yet that expence, Mr. Beatson says, is no doubt very great, especially in those places where many heavy-loaded carriages are continually passing. The ruts made by the wheels soon become so deep, and the materials of the road are thereby so much torn up, that it is almost an impossibility, however hard the materials, to keep the road for any considerable time in proper condition, or state of repair. It is, therefore, suggested, that these effects should be attempted to be remedied by some means or other, as by a sort of roller so fixed as to prevent the wheels from sinking so as to form ruts.

It is evident that the principles and directions which have been given apply equally to private or parochial roads, which in general are in a worse condition, from their being commonly worse managed. The causes of their being in bad condition should be attended to and removed, as much as possible, in the manner already suggested, as it is evident that they must have a great effect in promoting improvements in agriculture, by lessening the expence of labour, and facilitating the means of conveyance of different articles. The effects of some sorts of wheels have been more destructive to roads than others, and of course acts of parliament have been formed with the view of affording proper regulations in this respect. See WHEEL and WAGON.

In speaking of the draft from friction on the roads, Mr. Middleton, after considering what happens on those made with gravel, and on iron railways, concludes, that, on gravelled roads, friction is not more than one-fifth part of the entire draft; the other four-fifths being occasioned by the

the obstacles of dust, sludge, loose sand and gravel. Hence it follows, he thinks, that by removing these obstructing causes, and keeping the roads constantly clean and hard, the draft would be so much lessened, as to render the present number of labouring horses unnecessary. It is suggested, that many of these inconveniencies may be got rid of; and the roads be in the way of getting more dry, clean, and hard, by removing the offending matter while in the state of dust, when it occupies the least possible space, and is in the most favourable condition for being taken away. A small portion of dust, it is said, when drenched with rain, becomes a large quantity of sludge, in which state it requires much labour to clear it away; on which account it is very advantageous to get quit of it before rain falls. This is, it is supposed, best effected by means of hush-harrows wrought every windy day. But some might be taken away after being scraped together by suitable machinery for the purpose.

It is intimated, that the time seems to be approaching, when iron must be made to contribute largely towards the public roads. It is thought that iron rails, or bars, may be laid along the present turnpike roads, in such a manner as to afford the most convenient track for all heavily laden carriages; and that this may be done without any material inconvenience to those of lighter weight and swifter speed. The great original expence of making such roads will, it is supposed, be sufficiently counterbalanced by their much longer duration, and the trouble fully compensated by the superior pleasure of travelling over them.

On the whole, it is supposed, that the keeping of roads in the most perfect repair is an object of high importance; for that until canals, or inland navigation, became general, the supply of the markets, and the price of every article, will be in proportion to the state of the roads over which they have to pass in their way to towns. Bad roads, it is said, require a greater number of horses to draw any given weight along them, than would be necessary for the conveyance of the same weight over good ones; which extra draft must be paid for by increasing the price of the article to the consumer. The same number of horses which, along *bad roads*, could only bring a scanty supply of the produce of the country from a small distance, can, on *good roads*, convey a more abundant supply, and from greater distances: which is calculated to lower the price of the necessaries of life in the metropolis and other large towns, rather than *advance* them in the distant counties, and have a happy tendency towards *equalizing* the prices between the towns and the country.

And the author of the paper already noticed, thinks it a matter of great consequence to have proper regard to the nature of the fences on the sides of roads, as on these the goodness of them, and the expence of upholding them, very much depend. Where the form of the ground and situation will admit of it, the sunk fence from the road, that is, with the deepest part towards the field, is by far the best. A fence of this sort, in the form of a ditch or drain, may be made of any depth without the least danger or inconvenience, which is not the case when open to the road; and the deeper it is made, the better effect it will have in keeping dry the foundation of the road, if properly constructed; nor will the road require to be so wide as usual, at the same time there will be fully more room to travel on; for if the fences are of this kind, the whole width of the road may with safety be occupied, but when open to the road a considerable space is lost, by the fear or danger of approaching too near them. And the fences on the sides may either be of stone, sod, or a hedge or paling; but ought not to be more than eighteen

inches, or two feet above the level of the road (except a paling), and the top of them, if broad enough, may, in some places, be made to serve as a foot-path. Nevertheless, the fence towards the field may be six feet in height, or as high as the purpose of it requires. The road will thus receive the whole benefit of the sun, which is very essential towards keeping it dry, as well as the depth of the drains or ditches within the field, to which there must be proper openings at certain distances, as before recommended; and in winter, after heavy falls of snow, there will be little chance of a road fenced in this manner ever being blocked up, for it will be observed, when a storm of snow is attended with a high wind, that the drifted snow lodges chiefly about the fences, or where it meets with an obstacle to occasion an *eddy*; for where high fences are on the sides of roads, they are almost to a certainty in such cases blocked up, to the great inconvenience of the whole neighbouring country or district in which it happens. The planting of trees on the sides of roads should always be avoided as much as possible; but where rows of them are to be put in, it should never be done at less than ten or twelve feet distance from the fences, and not less than forty or fifty feet from each other, being constantly so situated as not to produce much shade on the road in the middle of the day.

ROAD, in *Ornamental Gardening*, that sort of carriage-way which is peculiar to residences of the country kind. They are of many different sorts, according to the nature, circumstances, and situations of the different places. But when properly laid out and formed, they have mostly one of the effects of building, at least, in a partial manner, which is that of giving force and spirit to scenes of verdure and cultivation. They should be laid out according to the nature of the situations; their directions and widths being provided by their conveniences, propriety, and utility. The methods of making and repairing of them are much the same as those employed for other kinds of roads; but in the finishing, their surfaces should be laid over with a finer and better coloured material of the gravel or some other sort, and they should be kept more perfectly rolled down and level; as the colours of such surface materials and the margins of such roads are principally what concerns picturesque effect, or that which is to be produced by them. In situations where the scene is avowedly of the artificial kind, the margins of them, according to the author of the work on "Country Residences," should be parallel to each other, and correctly defined; as in that part of an approach-road, which comes within the parapet or fence which incloses the mansion, or in those roads which are within the bounds of the other more adorned parts of the ground. But in situations where the roads are not in these scenes, but are either in picturesque or natural pleasure-grounds, pasture-fields, parks, forests, dingles, or other similar places, the edges should be irregular, and more or less rough or smooth, blending or ragged, as is seen to take place in roads or tracks through similar scenery in wild nature. The excellent effects and superior advantages which result from the adoption of these principles in the formation and construction of roads of this nature, may often, it is said, be seen in those parts of much frequented approach-roads of residences, which are not thought proper or necessary to be subjected to the operation of the paring-iron, and the formal trimming of the gardener. And indeed, that one of the most striking deformities in picturesque scenery, is that of the formal, stiff, and harsh edges of made roads, as they highly disgust the spectator, and prevent the true effect which should be produced.

All roads of this sort should, therefore, be laid out, and formed

formed in such a manner as to harmonise as perfectly as possible with the nature, circumstances, situations, and scenery of the particular places in which they are to be had recourse to. See *WALK*.

*ROAD, Approach*, that variety of this sort of road which is peculiar to residences, mansions, or houses of the country kind, and which leads or conducts to their principal or other entrances. In their manner of being laid out, they should in their directions neither be too affectedly graceful, have too much waving in their appearance, be too much beset and intercepted with trees; or be too vulgarly formed in the rectilinear and direct manner, or be too abrupt in their nature. There is a certain kind of dignity, propriety, and fitness requisite in them, which is not easily described, but which, in given situations and circumstances, readily presents itself to the mind of the designer; and in consequence of the whole of the operations, both of conceiving and designing them, being so simple, they are, for the most part, marked out upon the ground with great facility,—easily improved upon, and, in their execution, the work is merely that of road-making.

The accompanying circumstances which appertain to roads of this nature have been already pointed out in speaking of them in general, and they ought to be well attended to, as much of their beauty and effect arise from them.

The only proper approach-roads to castles, Mr. Loudon says, have been supposed those of the avenue kind, but that there seems no reason in nature for such a rule; and the arguments drawn from antiquity are wholly insufficient to justify their constant introduction in such cases. However, wherever they exist with good effect, they should, it is said, be carefully preserved; and even, in some situations, avenue roads to mansions, straight private roads through monotonous cultivated countries, or public roads passing along eminencies, may be created and formed with great advantage and effect, as is the case in many places. Roads of this kind should always be so contrived as to afford the best effect, and to produce the greatest harmony, which the places are capable of admitting.

*ROAD, Drive*, another description of road belonging to residences of the rural sort, which is chiefly designed to shew and display the beauties of the places, or of the surrounding country, or of both at the same time. They are principally had recourse to in residences of the more extensive and elegant kind, being mostly contrived without any great difficulty. The main circumstance to be attended to in this business, is that of only shewing one sort of rural character at one time, but to display the whole, in succession, as much as possible. They are commonly formed, as to the road part, without much labour or trouble, being often simply made by levelling, and the materials upon the spot; they may, however, be constructed in the same manner as the other roads in such situations.

The leading, or striking characters of the spot, are here to be particularly regarded.

*ROAD-Gage*, a contrivance for the purpose of breaking road stones, or other hard materials, by. A ring, or an oval, of iron, of the proper size for the intended use, with a short handle fixed to it, will answer this intention very well. These gages are of great use in breaking stones by the load, or in other ways, before they are laid upon roads; and should always be known to the workmen previous to their undertaking the business. See *ROAD Stones*.

*ROAD-Harrow*, an implement of the harrow kind, contrived for the purpose of forcing in the sides of the ruts. One represented in the Essex Agricultural Survey levels the

ruts and combs very expeditiously. It was invented by Mr. Patten, and costs 5*l*. See *ROADS*.

*ROAD-Horse*, such a one as is employed in the teams on the road, and which in general performs the most laborious work. Under this description comes the greater part of all the horses in constant use, as it includes carriage horses of every kind, roadsters, and hacks. Road-horses of every denomination are, from their constant hard work, entitled to a proportionable degree of care and attention with the best horses in the kingdom; and should undergo the useful part of stable management, that so much contributes to the preservation of health in horses of a superior description. Those which have incessant labour, or which travel post, must be supplied with at least from one to two pecks of corn a day. Large and strong carriage horses, in perpetual work, require considerably more, or they will become apt to lose flesh by frequent perspiration. These rules, however, offer only a kind of general standard.

*ROAD-Materials*, all such substances as are employed, or made use of, in the making and repairing of roads; as those of stony matters of different kinds and qualities, various sorts of gravel, sand, and a variety of other articles. They should, in every case, be reduced as much as possible to the same sizes, as the regular wear of roads depends very much upon it. See *ROAD*.

*ROAD-Pick*, an useful implement of this kind with three points. It has much resemblance to the common pick-axe, only differing from it in having the flat edge-like end of that tool occupied by three strong tines, about six inches in length, and standing about six inches in width from the outside to the outside of them. It thus forms a sort of small trident, which is borne on the shank of the implement, and stands about six or eight inches from the socket and handle.

It is a very convenient tool in striking off the protuberances, and filling in the ruts of hard roads; as well as to level and adjust the surface with, in forming and repairing stone roads. The single end is likewise capable of being employed for letting off water from shallow ruts, or hollow places, as well as for many other uses of the common pick. See *PICK*.

*ROAD-Plough*, an instrument of the plough kind, invented and made by the late Mr. Brand, an ingenious blacksmith, in the county of Essex, at Lawford, near Manningtree. It is formed all of iron, and represented in the Agricultural Survey of that district. Its length is that of a common plough, with two small wheels, one before and the other behind; and the coulter part is strongly secured.

*ROAD-Roller*, a heavy kind of iron roller, formed in three separate parts, used for rolling down the loose materials on roads. It is drawn by a horse or horses in shafts, somewhat as in the common roller. See *ROADS*.

*ROAD Scraping Machine*, a contrivance made for the purpose of cleansing roads from dirt, &c. These machines are constructed in several different ways, by different makers; but a very useful one may be seen under the head *Machine*; which see. See also *ROAD*.

*ROAD-Stones*, all kinds of stones, whether of the field, quarry, or other sorts, that are employed in the forming and mending of roads. For some uses of this nature, the stones should be considerably reduced, even in constructing or repairing ordinary roads. Mr. Marshall has suggested, that by dropping road-stones through circular gages of different sizes, it will be found that, for repairing small breaches, those which pass freely through a ring, 2½ inches in diameter, may be considered as of a middle size; and that

that for new forming or fresh covering the surface of a road, none ought to exceed 4 inches;  $3\frac{1}{2}$  inches being, for these purposes, the middle size; that 2 inches and 4 inches may, as a matter of general information, be set down as the extremities of size of road-stones of a middle quality, for the above purposes. See *ROAD-GAGE*.

*ROAD-Surveyor*, a person who has the care and management of a road, whether in the making or repairing of it. All such persons as are employed in this way should be well acquainted with the nature of laying out, forming, and keeping them in order. Each of the different methods, which are in common practice, ought to be well understood, as well as those had recourse to in particular districts or places. And, besides, he should be well informed with regard to every thing of a local nature that has any relation to them, and be a man of exertion and ingenuity.

*ROAD-Team*, any sort of team that is employed on the road, whether in carts, waggons, or other kinds of carriages. All teams of this nature should in general be well kept. See *TEAM*.

*ROAD-Work*, all such kind of work as is done upon the road, either by the labour of men or animals. It is also sometimes applied to the business of making and repairing of roads.

*ROAD*, in *Navigation*, denotes a place of anchorage at some distance from shore, and sheltered from the winds, where vessels usually moor to wait for a wind or tide proper to carry them into harbour, or to set sail.

When the bottom is clear of rocks, and the hold firm, and the place well covered from the wind, the road is said to be good. An open road is one which has but little land on any side.

The roads within his majesty's dominions are free to all merchant vessels, either of his subjects or allies. Captains and masters of ships who are forced by storms, &c. to cut their cables, and leave their anchors in the roads, are obliged to fix up marks or buoys, on pain of forfeiture of their anchors, &c.

The masters of ships, coming to moor in a road, must cast anchor at such a distance as that the cables, &c. may not mix, on pain of answering the damages. When there are several vessels in the same road, the outermost to the seaward is obliged to keep a light in his lantern in the night-time, to apprise vessels coming in from sea. See *PORT*.

*ROAD Aqueduct*, is an arch under a canal, through which a road passes.

*ROAD Bridge*, a bridge over a canal for the use of a road, instead of private use. See *OCCUPATION Bridges*.

*ROAD, Cock*. See *COCKROAD*.

*ROAD-Goose*, in *Zoology*, the name of a small species of wild goose. See *Anser* under *DUCK*.

*ROADER*, a vessel riding at anchor in a road, bay, or river.

*ROADING*, a term used on the Fen rivers, for cutting off the weeds at their bottom.

*LOADING*, in *Agriculture*, a provincial term used to signify the striving of teams for the lead on the roads. It was formerly much in use in Norfolk, but is at present nearly laid aside, probably from the danger that attended it.

*ROADSTER*, among *Horses*, a term frequently applied to such as are used for the purpose of riding.

*ROAITHA*, or *ROUAITHA*, in *Geography*, a town of Arabia, in Yemen; 56 miles S. of Medina.

*ROAK*, a provincial word, signifying a mist or fog.

*ROAN*, in *Geography*, a small island in the North sea,

near the north of Scotland. N. lat.  $58^{\circ} 35'$ . W. long.  $4^{\circ} 11'$ .

*ROAN*, in the *Manege*. A roan horse is one of a bay, ferrel, or black colour, with grey or white spots interspersed very thick. When this party-coloured coat is accompanied with a black head and black extremities, he is called a roan with a black-a-moor's head; and if the same mixture is predominant upon a deep ferrel, it is called claret-roan.

*ROANCARRICK Rocks*, in *Geography*, rocks in Bantry bay, on the S. coast of Ireland; 3 miles N.E. of Beat island.

*ROANE*, a county of America, in the district of East Tennessee, containing 5581 inhabitants.

*ROANE-Tree*, in *Botany*. See *SERVICE-Tree*.

*ROANNE*, in *Geography*, a town of France, and principal place of a district, in the department of the Loire, which here becomes navigable, and renders it a convenient staple for all goods conveyed from Lyons to Paris, Orleans, Nantes, &c. The place contains 6992, and the canton 14,790 inhabitants, on a territory of 225 kilometres, in 13 communes. N. lat.  $46^{\circ} 2'$ . E. long.  $4^{\circ} 10'$ .

*ROANOKE*, an island in the Atlantic, on the coast of North Carolina, at the entrance into Albemarle sound, with a town of the same name. The north point of the island is about 7 miles W. of Roanoke inlet. N. lat.  $35^{\circ} 50'$ . W. long.  $76^{\circ}$ .—Also, a long and rapid river, formed by two principal branches, *viz.* Staunton, which rises in Virginia, and Dan, which rises in North Carolina. It empties itself into Albemarle sound, about N. lat.  $35^{\circ} 58'$ . W. long.  $76^{\circ} 56'$ . This river is navigable for sea-vessels nearly 30 miles; but for boats of 30 or 40 tons, to the falls. Above the falls, boats of 5 tons ascend about 200 miles. The planters on the banks of this river are supposed to be the wealthiest in North Carolina.

*ROANOKE, Little*, a river which discharges itself into the Staunton, about 15 miles above the junction of the Dan and Staunton.

*ROANOKE Inlet*, a channel on the coast of North Carolina, which leads into Albemarle sound. N. lat.  $35^{\circ} 56'$ . W. long.  $76^{\circ} 14'$ .

*ROANPOUR*, a town of Bengal; 17 miles S.S.E. of Mauldah.

*ROARAGUR*, a town of Hindoostan, in Vissapour; 22 miles N. of Sottarah.

*ROARING BULL Island*, an island in the North Atlantic ocean, near the east coast of Nova Scotia. N. lat.  $45^{\circ} 17'$ . W. long.  $60^{\circ} 44'$ .

*ROARING River*, a river of America, in the state of Tennessee, which runs N.W. into Cumberland river, 12 miles S.W. of the mouth of Obas river.

*ROARING Water Bay*, a bay on the S. coast of Ireland, in which is a number of small islands; 6 miles S.W. of Skibbereen. N. lat.  $51^{\circ} 28'$ . W. long.  $9^{\circ} 22'$ .

*ROARING Water*, a river of Ireland, which runs into the fore-mentioned bay, 5 miles W.S.W. of Skibbereen.

*ROASCHIA*, a town of France, in the department of the Stura; 8 miles S.W. of Coni.

*ROASTING*, in *Metallurgy* and *Chemical Manufacture*, is a process by which the volatile parts of metals and minerals are separated by the application of heat. The minerals are generally mixed with the fuel, and fired in heaps exposed to the open air. When the volatile substance is driven off with difficulty, the reverberatory furnace is sometimes employed.

This process is frequently, though improperly, called *calcining*, since the latter is confined to the oxydation of metals.

metals. In expelling the volatile parts from lime-stone and gypsum, the process is termed *burning*, and in the latter sometimes *boiling*. The term roasting is principally confined to iron, and other ores abounding with sulphur and arsenic.

The iron ores of this country are roasted for the purpose of expelling sulphur, water, and carbonic acid. The former would probably injure the quality of the iron in smelting; the latter would contribute to an expenditure of the heat of the furnace. The process is conducted in the open air, by piling the iron-stone and small coal in alternate strata, allowing the mass to burn till the coal is consumed. The iron-stone, by this means, becomes of a red colour, and loses much of its weight. In some iron-works the process is performed in kilns, similar to those employed for burning lime-stone.

The ore from which zinc is obtained is generally blende, which is the sulphuret of that metal. It is exposed to the strong heat of a reverberatory furnace, by which the sulphur is expelled, and the metal oxydated.

When the metals or their oxyds are themselves volatile, and are combined with sulphur, roasting is not practicable: recourse must then be had to some other agent, which will combine with the sulphur, and separate the metal itself. Such is the case with *cinnabar* and *arsenic*. See the respective metals.

**ROASTING, in Domestic Economy.** When that change by heat which animal food undergoes to render it fit for digestion is brought about by a temperature capable of partially changing the surface, the process has been termed roasting; a similar change in vegetable food, such as bread, puddings, and pies, being termed baking. The most ancient method of roasting, which is still the general practice, is by turning the meat before the fire; and it is still supposed, without any good reason, that meat cannot have its proper flavour when roasted in any other way. It is true that *roasters* or *ovens* of the common construction are apt to give the meat a disagreeable flavour, arising from the empyreumatic oil which is formed by the decomposition of the fat, exposed to the bottom of the oven. This evil has been completely remedied in two ways, first by providing against the evil of allowing the fat to burn, and secondly by carrying off by a strong current of heated air the empyreumatic vapours.

The roaster used in the Derby Infirmary, and in many private houses in the neighbourhood, is not on any account objectionable, but it is particularly valuable in an economical point of view. This is principally effected by casting the heat entirely upon the object of roasting, instead of sending three-fourths of the heat up a capacious chimney, and expending the greatest part of the remainder upon the cook, and the walls and furniture of the kitchen.

The roaster above alluded to is made of sheet iron, of the strength of about one pound to the square foot: its form is that of a parallelepipedon, about twenty-five inches high, twenty-two long, and eighteen in breadth. The fire is put under it; but one course of bricks is placed immediately over the fire, and above this a cavity of five inches deep between the brick roof and the oven bottom. The flame of the fire passes a little to the right and left, and rises perpendicularly up the sides of the roaster, freely communicating with the top of the same. By this means the flame and hot vapour will be the hottest at the top of the oven, because of its greater levity, and its not being allowed to escape at this point, according to the common practice. After the hot vapour has bestowed its heat on the superior part, it now descends and enters on each side the cavity under the oven, from whence it passes up the back of the same,

which back forms one side of the smoke chimney. This arrangement is sufficient for distributing all the disposable heat equally on every side of the roaster. We shall next point out the contrivance for disposing of the smell above alluded to. The door of the oven is cased with wood, a piece of thick paper, steeped in a solution of alum, and smeared with clay, being placed between the wood and the iron, to prevent the wood from being charred. The door extends below the bottom of the oven about three inches. This, when the door is open, exposes a plate three inches deep, and the width of the oven, and which constitutes the front of the cavity under the oven. At one side of this plate is a hole at the entrance of the tube, which extends to the other end of the cavity, where it is bent, and returns on the other side of the cavity, and opens into another cavity formed by a double plate, which constitutes the iron part of the door. The first entrance of this tube corresponds with an opening at the bottom of the door, so that when the door is shut, cold air can enter the tube. In its passage it becomes heated, and then enters the oven at the top, from the cavity in the door. It now passes over the meat, and escapes through a tube in the back plate, which extends so high as to reach above the smoke damper. By this means the roaster is constantly cleared of any disagreeable vapour, by a force equal to the draft of the chimney.

A sliding rake is made, so as to fit the top and sides of the oven, that the whole surface becomes perfectly scraped by one motion.

**ROATO, in Geography,** a town of France, in the department of the Tanaro; ten miles N.W. of Asti.

**ROB, in Pharmacy,** the inspissated juice of any substance, usually boiled up to the consistence of honey.

There are robs made of quinces, sloes, cherries, mulberries, elderberries, barberries, gooseberries, and other fruits, for various diseases. The juice of grapes, thus prepared, is more particularly called rob, or *sapa simplex*; this is almost of the consistence of honey.

When only one-third of the humidity is boiled away, it is called *defrutum*; and when only boiled to the consistence of a soft electuary, a *resin*.

The word *rob* is pure Arabic; and signifies originally a juice dried in the sun, or over the fire, that it may keep the longer without damage.

Sometimes it also denotes a composition of some juice made up with honey or sugar, in which sense it is confounded with *loche* or *lohoc*.

The rob is a form now much out of use, though there are several directed in the college dispensatory; as robs of black cherries, of sloes, of quinces, of elder, &c.

It is possible that great improvements might be made, by introducing the use of this form among the malt-distillers. The great inconvenience attending that art being, that the malt being of a large bulk, in proportion to its saccharine part, and requiring a larger proportion of water to extract that saccharine part, many large vessels, such as mash-tubs, coolers, fermenting backs, &c. are necessary; and the necessary labour on the subject is increased, and the commodity rendered dearer. The remedy of this should seem the introducing a new art subservient to that of the malt-distiller, and confining itself to the boiling down of malt-wort to a rob, so as to supply the malt-distiller with his subject, in the same manner as the fine-distillers are supplied with treacle from the sugar-baker. By this means the business of the malt-distiller would be reduced to a great degree of simplicity, and the spirit produced would be also much finer than at present, because the subject would come tolerably refined to his hands, and purged of its gross, mealy, and husky matter,

which yields a difagreeable oil in diffillation, and is alfo apt to burn to the ftill, and fpoil the fpirit. It is poffible that a fpirit purer and finer than that from treacle might this way be procured from malt, prudently managed. Shaw's Lect. p. 219.

ROBALI, in *Geography*, a town of Abyffinia; 75 miles S. of Miné.

ROBALO, in *Ichthyology*, a name by which fome have called the *camuri*.

ROBARES, in *Geography*, rocks near the S. coaft of Ireland; three miles S.E. of Gally Head. N. lat. 51° 31'. W. long. 8° 50'.

ROBASOME, a town of France, in the government of the Po; eight miles N.N.W. of Turin.

ROBBEN, or SEAL, *Ifland*, an ifland on the coaft of Africa, near the Cape of Good Hope, at the entrance into Falfe bay, about fix miles in circumference. It ferves as a place of exile for criminals fent from the Cape or the Indies, who are compelled to labour, and are guarded by twenty-four foldiers under the command of a ferjeant. No women are permitted to live upon the ifland. Within this ifland and the continent there is excellent anchorage, where fhips driven out by the S.E. winds, which blow from September to the end of April, the feafon when all fhips bound for the Cape refort to Table Bay, ufually bring up. Here, too, fhips intending to come into Table Bay ufually wait the abatement of the S.E. wind, if it fould happen to be too ftrong for their working up againft it. This ifland is too fmall, and at too great a diftance, to afford the leaft fhelter to Table Bay in the N.W. winds that blow in the winter months. S. lat. 33° 40'. E. long. 18° 20'.

ROBBERY, ROBERIA, or *Roberia*, in *Law*, a felonious and forcible taking away another man's goods or money, from his perfon, prefence, or eftate, by putting him in fear, &c. 1 Hawk. P. C. 95.

A mere attempt to rob was held to be felony, fo late as Henry the Fourth's time (1 Hal. P. C. 532.); and afterwards it was only a mifdemeanor, and punifhable with fine and imprifonment, till the ftat. 7 Geo. II. cap. 21. which makes it a felony, tranfportable for feven years, unlawfully and maliciously to allault another, with any offensive weapon or inftrument, or by menaces, or by other forcible or violent manner, to demand any money or goods, with a felonious intent to rob. If the thief, having once taken a purfe, returns it, ftill it is a robbery. The previous putting in fear is the criterion that diftinguifhes robbery from other larcenies; and yet this putting in fear does not imply any great degree of terror or affright in the party robbed; it is fufficient that fo much force, or threatening by word or gesture, be ufed, as might create an apprehenfion of danger, or oblige a man to part with his property without or againft his confent. (Foft. 128.) Thus, if a man be knocked down without previous warning, and ftripped of his property while fenfelefs, though ftictly he cannot be faid to be *put in fear*, yet this is undoubtedly a robbery; or, if a perfon with a fword drawn beg an alms, and I give it him through miftruft and apprehenfion of violence, this is a felonious robbery. 1 Hawk. P. C. 96.

This is fometimes alfo called *violent theft*, and its punifhment, be the value of the thing taken ever fo fmall, is death.

This fpecies of larceny is debarred of the benefit of clergy by 23 Hen. VIII. cap. 1. and other fubfequent ftatutes; not indeed in general, but only when committed in or near the king's highway. A robbery, therefore, in a diftant field or foot-path, was not punifhed with death (1 Hal. P. C. 535.), but was open to the benefit of clergy, till the

ftat. 3 & 4 W. & M. cap. 9. which takes away clergy from robbery wherefoever committed.

The word is faid to have taken its rife hence, that antiently robbers only took away the *robes* or clothes from travellers. Though lord Coke, in the third of his Inftitutes, takes the name to have had its rife from Robin Hood, who lived under Richard I. in the borders of England and Scotland, by robbery, burning houfes, rape, and fpoil. Hence, alfo,

*Robbers-men*, or *roberds-men*, mentioned in feveral ftatutes for great thieves.

ROBBING. See *HOUSE-Robbing*.

ROBBINS, or ROBANDS, *i. e.* *rope-bands*, in a *Ship*, fmall lines, or braided cordage, which make the upper edges of the great fails faft to their refpective yards, being reeved into eyelet-holes in the head of the fail under the head-rope for that purpofe. They are generally of a fufficient length to pafs two or three times about the faid yard. The word is, *make faft the robbins*; for at fea they do not fay, *tie*, but *make faft*.

ROBE, ROBA. See *GOWN*.

ROBES, *Mafter of the*, is an officer of the houfehold, with an appointment of 500l. a-year, who has the ordering of all his majesty's robes. See *MASTER of the Wardrobe*.

He has feveral officers under him, as a clerk of the robes, a yeoman, three grooms, a page, a brusher, furrier, fempftrefs, laundrefs, ftarcher, and ftanding wardrobe-keepers at St. James's, Windfor caftle, Hampton-court, &c. There is alfo in the eftablifhment of his majesty's houfehold a miftrefs of the robes, with an appointment of 500l. a-year, and two keepers of the robes. See *WARDROBE*.

ROBES to *Minftrels*. Innumerable bands of tumblers, buffoons, rope-dancers, muficians, players on inftruments, and aftors, were formerly retained in the courts of princes, who, by their gambols, farces, fports, and fongs, diverted the company. Thefe were called in Tufcany *Giullare* and *Giocolari*, and, by thofe who mentioned them in Latin, *Jocularis* and *Joculatores*. Thefe fabricators of amufement never departed without being well rewarded. But what appears the moft extraordinary and different from our prefent cuftoms is, that the coftly and gorgeous robes, which it was ufual for princes to receive from other great perfonages who vifited their courts at feaft, or upon their marriage, as marks of their friendship and refpect, were beftowed on thefe people. Benvenuto Aliprando, an old ruffic poet, in his Chronicle, defcribes a marriage at the great court of Mantua, in the year 1340, while under the dominion of the Gonzaga family. "At that time," fays he, "the different princes and nobles of Italy, whose names he mentions, prefented the Gonzaghi with a variety of rich and precious veltments, which were called *robe*, robes, and which were afterwards given to muficians and buffoons," as the old poet informs us in the following lines:

" Tutte le robe fopra nominate,  
Furon in tutto trent' otto e trecento,  
A buffoni e fonatori donate."

" And all thefe coftly robes of ftates,  
In all three hundred thirty-eight,  
To fidlers and buffoons were given."

The family of Gonzaga, in return, reciprocally exercifed munificence towards the nobles who vifited them, as the fame old poet informs us in the following rude verfes:

" Otto giorno la corte fi durare  
Torni eri, gioftri, bagordi faccia,

Bellar, cantar', e tonar facem taro,  
 Quattro cento sonator si dicia  
 Con buffoni alla corte si trovoc.  
 Roba e danar donar lor si facia.  
 Ciafcun molto contento si chiamoc, &c."

" Eight days these sports were held, where valiant knights  
 In tilts and tournaments their prowess show,  
 And minstrels, full four hundred, crown the rites,  
 While dance and song teach ev'ry heart to glow.  
 To these and each buffoon who here was found,  
 Or gold was given, or robes of costly sort;  
 And all, so well their spritely arts were crown'd,  
 Depart contented from the splendid court."

With what magnificence the princes of the house of Visconti supported their court at Milan, during the same century, is frequently described by Corio the historian; but he particularly excites our wonder by his account of the solemn pomp with which the nuptials of Lionel, duke of Clarence, son of Edward III. king of England, was celebrated in 1368, with Violante, the daughter of Galeazzo Visconti, duke of Milan. This event is circumstantially related by several other ancient historians of Italy; and Aliprando of Mantua tells us, that Lionel gave five hundred superb dresses to the minstrels, musicians, and buffoons, who were then assembled at Milan; that Galeazzo presented them with many more; and Bernabo, his brother, rewarded them munificently with money on the occasion.

The splendid robes and gorgeous attire of bards and minstrels at all times are upon record. The flowing vest of Orpheus, in the triple capacity of priest, legislator, and musician, is specified by Virgil; Arion is related by Herodotus to have leaped into the sea, in the rich vestments he usually wore in public; Suidas speaks of the saffron robe and Milesian slippers worn by Antigenides; and the performers in the tragic chorus, which used to be furnished at the expence of some wealthy citizen of Athens, wore also a splendid and costly uniform.

In France the *Jongleurs*, and in Provence the *Troubadours*, or minstrels, during the middle ages, had frequent presents of costly robes from their patrons. In the "Fabliau Conte," or Tale of the red Rose, a female complains to a *vavassor*, or yeoman, of his having taken from her a robe, to give to the minstrels.

" Bien doit estre vavassor vis,  
 Qu'il vuet devenir menestrier;  
 Miez voudroi que fussiez rez, (rafé)  
 Sans aigue (eau) la tette & le coul,  
 Que ia n'y remanfit chevol,  
 S'apartient à ces jongleours,  
 Et à ces autres chanteours,  
 Qu'ils ayent de ces chevaliers,  
 Les robes, car c'est lor meltiers."  
 Fabliau de la Rose vermeille.

" I would not own the wretch for kin,  
 Who wou'd the minstrel trade pursue,  
 He'd better *dry* shave head and chin,  
 And, with the hair, cut off the skin,  
 Than herd with such a worthless crew.  
 Let splendid knights with usual pride,  
 On siders lavish such rewards,  
 But 'tis to meaner fools denied  
 To trip themselves for vagrant bards."

The custom of presenting musicians with superb and expensive dresses during the 14th century, in the manner al-

ready related, seems to have travelled into England, and to have continued here till after the establishment of the king's band of four-and-twenty performers; part of their present salary being still paid at the wardrobe office, as an equivalent for the annual dress with which they used to be furnished at his majesty's expence. To this we may add, that the *waits*, or musicians who attend on the mayor and aldermen, in most of our incorporate cities and towns, are furnished with splendid cloaks.

ROBE, in *Geography*, a river of Ireland, which, rising in the eastern part of the county of Mayo, flows westward by the town of Ballinrobe; a few miles west of which it discharges itself into Lough Mask.

ROBEC, a river of France, which runs into the Seine, a little below Rouen.

ROBEK, a river of France, which runs into the Meuse, near Stevenwaert.—Also, a river of France, formed by the union of the Clarence and the Nevec, which, after a short course, runs into the Lys, 2 miles E. of St. Venant.

ROBEK, or *Robeque*, a town of France, in the department of the Straits of Calais; 3 miles S. of St. Venant.

ROBEL, a town of the duchy of Mecklenburg; 9 miles S. of Wehrau. N. lat. 53° 10'. E. long. 12° 45'.

ROBER, a river of France, which runs into the Moselle, at Treves.

ROBERDSMEN. See ROBBERY.

ROBERGIA, in *Botany*, received that appellation from Professor Schreber, in memory of Laurence Roberg, professor of physic in the university of Upsal, who was born in 1664, and died in 1742. His most curious, though very candid and superficial publication, entitled *Grundvahl til Plantekjenningen*, is an anonymous introduction to botany, on Tournefort's plan, of 20 duodecimo pages, with as many rude wooden cuts of flowers, to illustrate the principal classes. Of the fifteen various inaugural dissertations, published under the presidency of Roberg, only two are botanical; one being that of John Olaus Rudbeck, on the *Sceptrum Carolinum* (see RUDBECK); and the other by Lofsberg on the Generation of Plants.—Schreb. Gen. 309. Willd. Sp. Pl. v. 1. 752. Mart. Mill. Dict. v. 4. (Rourea; Aubl. Guian. v. 1. 467. Juss. 369.)—Class and order, *Decandria Pentagynia*. Nat. Ord. *Terebinthaceæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, roundish, concave segments, permanent. Cor. of five roundish petals, the length of the calyx. Stam. Filaments ten, inserted into the receptacle, the length of the corolla; anthers roundish. Pist. Germen superior, roundish, villous; styles five, capillary; stigmas rather thick, furrowed. Peric. Drupa ovate, most convex on one side, slightly hollowed out at the other. Seed. Nut the shape of the drupa, of one cell, with a bivalve shell.

Ess. Ch. Calyx in five deep segments. Petals five. Drupa superior, of one cell. Nut with a bivalve shell, and single kernel.

1. *R. frutescens*. Willd. n. 1. (Rourea frutescens; Aubl. Guian. v. 1. 467. t. 187.)—Native of woods in Guiana, belonging to the parish of Aroura, flowering in August. The stem is shrubby, supporting itself by branching over the neighbouring trees. Leaves alternate, pinnate, of three or four pair, with an odd one, of stalked, elliptical, pointed, entire leaflets, from an inch and a half to three inches long; smooth above; downy and whitish beneath. Flowers in axillary, branched panicles, white, with a scent sweeter than that of lilac. Fruit black, with a greenish kernel.

ROBERT, in *Biography*, emperor of Germany, sur-

named the *Short*, born in 1352, was count palatine at the time of the deposition of Wenceslaus; and Frederic, duke of Brunswick, who was first elected by the German princes to supply the vacancy, having been assassinated, Robert was chosen in his stead in 1400. Wenceslaus had sold the dukedom of Milan to John Galeazzo, who had withdrawn his state from the sovereignty of the empire, and by force of arms had annexed to it several neighbouring towns and districts. Robert, therefore, invited by the pope and Florentines, led an army into Italy, and entered the duchy of Milan; but he was so much harassed, as to be obliged to march back to Germany, without having effected any thing. On his return he was involved in some petty wars with princes and states, who disputed his authority; and a confederation was formed against him, which subsisted during the whole of his reign. The most inveterate of his opponents was the elector of Mentz, who began to build a castle at Hochst, in defiance of him. Robert assembled troops to reduce him to obedience; but having advanced to Oppenheim, was seized with a fever, which proved fatal to him in 1410, at the age of 58. He was a prince of more prudence than enterprize, but possessed qualities which would have rendered his reign happy in less turbulent times. He was just, clement, and pious, an enlightened politician, and a lover of learning, as he manifested by founding the university of Heidelberg.

ROBERT, king of France, son of Hugh Capet, was associated by his father to the crown in 988, and succeeded him in 997, being then in his 27th year, and highly esteemed for his qualities both of body and mind. He had married Bertha, daughter of Conrad, king of Burgundy, and widow of Eudes, count of Blois. As he was distantly related to his queen, and had also stood god-father to one of her children by her former husband, his marriage was considered as invalid by Gregory V.; the parties were commanded to quit each other, and to submit to seven years' penance, on pain of excommunication. The king refusing to comply with this mandate, the sentence was issued against him, and the greater part of his own bishops joined in it. The effects of this excommunication are a striking example of the superstition of the age. The lords of his court broke off all intercourse with him, and the servants, who remained to wait upon him, shewed their horror of his situation by throwing to the dogs all the relics of food touched by the king or queen, and burning the vessels they had used. It was even reported that the queen was delivered of a monster. At length the king gave way, and parting with Bertha, by whom he had no issue, espoused Constance, daughter of the count of Arles, a beautiful woman, but violent and capricious, who disquieted all the remainder of his life.

The death of the duke of Burgundy, the king's uncle, without lawful heirs, in 1002, caused that rich inheritance to fall to the crown of France; and after a war carried on for some years with another claimant, Robert obtained possession of the country, with which he invested his second son, Henry. The termination of this war gave much satisfaction to the king, who was more inclined to the arts of peace than to military exploits; and he occupied himself in cares for the regulation of his court and household, and the cultivation of letters and religion among his people. He built and repaired many magnificent religious edifices, and merited the title of the devout. By the persuasion of the queen, he associated his eldest son, Hugh, in the government, in his 18th year. This prince, disgusted with the haughtiness and avarice of his mother, withdrew from court, and was guilty of some disorders; but by the mild treatment of his father, he was brought back to his duty. In

1022, Robert displayed his attachment to orthodoxy, by causing a council to assemble at Orleans, for the purpose of inquiring into a heresy introduced from Italy, which had been embraced even by some distinguished ecclesiastics. Several of the culprits were burnt alive, in the presence of the king and queen; the latter of whom manifested the fury of her zeal, by thrusting out an eye of one who had been her confessor, as he was led to execution. On the death of the emperor Henry II., in 1024, an Italian party offered the imperial crown and kingdom of Italy to Robert, or his son; but the king had too much wisdom to involve himself in a war on such a project. In 1026 he lost his eldest son Hugh; on which event, he associated in the crown his next son, Henry, notwithstanding the opposition of Constance, who preferred her son Robert. He died at Melun, in 1030, or 1031, about the age of 60, after a reign of 33 years. This prince was extremely beloved by his subjects, on account of his mildness, justice, and piety.

Robert was contemporary with Guido d'Arezzo. He was a great musician, and a good poet: he wrote several hymns for the church, and set them to music. They have been preserved among the ecclesiastical chants, and are still the most agreeable in its service. Constance, his second wife, pressed him to write a hymn in her praise; and he made her believe that the hymn "*Constantia Martyrum*" had been written for her, and she was satisfied.

Trithemius writes, that Robert made a pilgrimage to Rome, and deposited on the altar himself, at St. Peter's, his hymns, in the presence of the pope.

One of his best hymns is "*Veni, Sancte Spiritus.*" To him is likewise ascribed "*Chorus Novæ Jerusalem;*" the "*Prose on the Ascension;*" "*Rex omnipotens De odierna;*" "*Sancti Spiritus adit nobis Gratia.*" Laborde.

ROBERT I., king of Scotland, of the family of Bruce, memorable as the restorer of the independence of his country, was grandson of that Robert Bruce who was the unsuccessful competitor with John Baliol for the crown of Scotland. But the death of his father, who left him heir to his estates and pretensions, with that of John Baliol, whose son was a captive with the English, inspired him with high designs both for himself and his country, which was then in a state of subjection to Edward; and having left the English court, to which, it is said, his purposes had been betrayed, he arrived in Scotland about the close of 1305, with the resolution of declaring himself. The Scottish writers mention Comyn as the person who had given information against him; but whether this were the fact, or some other cause of quarrel rose between them, it is certain that at an interview at Dumfries, in February 1306, Bruce with his dagger stabbed Comyn, who was afterwards dispatched by one of his associates. This deed of violence could be justified only by greater daring; and Bruce immediately proceeded to seize the castle of Dumfries, to confine the English judges assembled there, to assert his claim to the crown, and to summon all the friends of his family to his assistance. He was soon at the head of a body of troops, with which he penetrated as far as Perth, the English every where flying before him; and in March he was solemnly crowned at Scone, in presence of some bishops and nobles, and a great number of gentlemen. The king of England, highly enraged at the news of these events, ordered all the forces of the northern counties to enter Scotland, and join the family of Comyn, in order to take vengeance on the rebel, as he was termed. The earl of Pembroke marched to Perth, where he surprised and defeated Bruce's troops at Methven, in June, their leader himself escaping with difficulty. The broken remnant of his army was again routed by lord Lorn, the

the nephew of Comyn; and Bruce, dismissing his few followers, was constrained to take refuge in an unfrequented isle of the Hebrides.

Neither friends nor foes were acquainted with the fate of Bruce, when he suddenly appeared at his estate of Carrick, at the head of a small but resolute band, with which he surpris'd an English lord, who had obtained a grant of that property; but on the approach of a detachment from the English army, he retreated to the Highlands. In the mean time, Edward was preparing for an expedition into Scotland with a force which was to reduce it to entire submission. He was soon after delivered from the most formidable of his foes, by the death of Edward I. near Carlisle, as he was just upon the point of entering Scotland with a great army. His son, Edward II., though he obeyed his father's dying injunction of marching into Scotland, yet pursued the war with no vigour, and soon returned to England to join his favourite Gaveston. Robert, who had reduced the western counties, left them in charge of his gallant friend, sir James Douglas, and proceeded against his enemies in the north. He afterwards made himself master of Inverness, and the northern districts; and at length, having taken the castle of Forfar and the town of Perth, he brought the whole of Scotland, except a few fortresses, to acknowledge his authority. In the beginning of 1314, there remained in Scotland only the castles of Stirling, Dunbar, and Berwick, in the hands of the English. Edward had now, after the death of Gaveston, reconciled himself with his discontented barons; and it was resolv'd that he should make an attempt to recover Scotland, with such a force as might overcome all resistance. At the head of the greatest army that had ever entered that country from England, he moved from Berwick in June 1314, and march'd for Stirling, to relieve its castle, then besieged by Robert in person. The Scotch army, much inferior in number to the English, but compos'd of veteran troops, await'd the approach of the enemy on the banks of the rivulet of Bannock, in the road to Stirling. In a skirmish of cavalry preceding the engagement, Robert display'd his strength and prowess by cleaving down to the chin, with his battle-axe, an opposite commander, of the family of Bohun. This was an omen of the success of the great battle of Bannockburn, in which, through the able disposition and conduct of Robert, the Scotch obtained the most decisive victory over the English that their annals boast, and established the independence of their country. Edward himself narrowly escap'd; and the number of noble prisoners was such as to enable Robert to recover, by exchange, his wife, daughter, and sister, with several men of rank, who had been the captives of Edward I. The king of Scotland follow'd up his success by an invasion of England, in which he ravag'd the northern counties without opposition. He now thought himself strong enough to give the English government molestation in another quarter; and in 1315 he sent his brother, Edward, over with a body of troops to the north of Ireland, to assist the natives in freeing themselves from the dominion of England. Robert himself follow'd with a large reinforcement in 1316, but was compell'd by famine to return; and his brother, after experiencing a variety of fortune, was defeated and slain in an engagement with the English near Dundalk.

The deposition and death of Edward II., in 1327, gave occasion to a breach of the truce on the part of the king of Scotland, who seems not to have consider'd himself as bound to the new government. In reality, however, he was tempted by the disorder'd state of England to renew hostilities, for which he had been some time preparing. Young Edward III. was not a prince to suffer an insult without

resistance and retaliation; and learning that the Scotch under Douglas and Murray, were making dreadful ravages in Northumberland, he assembled a powerful army, and went in search of them. They, however, eluded all his attempts to bring them to action, and retired to their own country. Edward dismiss'd his army, and in the same year a peace was agreed upon between the two nations, by an article of which the king of England renounc'd all claim to superiority over the kings or kingdom of Scotland; and thus the great object of Robert's reign, the independence of his country, was finally established. At the same time, his only son David, then five years of age, was contract'd to Joan, Edward's sister. Robert was now nearly worn out with the cares and fatigues of his active life; and in 1329, at his castle of Cardross, he expired, in the 54th year of his age and the 24th of his reign, leaving a name memorable in the annals of his country, which he rescue'd by his courage and wisdom from a foreign yoke, and restore'd to its rank among nations. Hume. Henry. Univ. Hist.

ROBERT, king of Naples, son of Charles II., by the sister of Ladislaus, king of Hungary, born in 1279, was duke of Calabria at the time of his father's death, in 1309. The succession was disput'd between him and the son of his elder brother, Carobert, king of Hungary; but the college of cardinals (Naples being then consider'd as a fief of the holy see) decid'd in Robert's favour. He was crown'd at Avignon, and, in gratitude to the pope, exerted himself to oppose the Ghibelline or imperial party in Italy. At this time the crown of Sicily was in possession of Frederic III. of Arragon, who, for his defence against the king of Naples, form'd an alliance with the emperor. Robert was ambitious to extend his dominion, and almost the whole of his reign was spent in fruitless attempts to conquer the island of Sicily. He also, during his contests with the Imperialists, aggrandiz'd himself in Lombardy, and for some time he held the sovereignty of great part of Romagna, Florence, Lucca, Ferrara, Genoa, and several other places in Piedmont. He was the most potent prince in Italy of his age; but it is less on account of his political and military successes that he deserves commemoration, than because he was the greatest royal proficient in science and letters, and the most munificent patron of them, in the century in which he liv'd. Many of the early writers give their testimony to his merits in this respect; and Petrarch, in particular, in several parts of his writings, is profuse in his praise. Robert, however, is said, when a child, to have been so slow of comprehension, that it was with the greatest difficulty he could be taught the elements of grammar; and it was not till his preceptor had interest'd him in Æsop's Fables, that he exhibit'd any fondness for learning. The private character of the king was highly amiable, and the only fault with which he is tax'd was a disposition to avarice, that grew upon him with his years. He had the misfortune of losing his only son, Charles, at the age of 31, on which occasion he exclaim'd that the crown was fallen from his head. He died in January 1343, in the 64th year of his age, and 34th of his reign.

ROBERT, CLAUDE, a French ecclesiastic and chronologist of some celebrity, was born at Chésey, a village between Bar-sur-Seine and Tonnerre, on the borders of Burgundy, in the year 1564. From some seminary in the province just mentioned, he went to pursue his academical studies at Paris, where he obtain'd an exhibition in the college of Cambrai. As soon as he had been admitted to the degree of licentiate in canon law, he accompany'd his pupil into Burgundy, where, in 1595, he was present'd to a canonry of the Chapel-aux-Riche at Dijon. Afterwards he travel'd with his pupil through

through France, Flanders, Germany, and Italy. At Rome he was introduced to persons of the greatest distinction, and received several marks of esteem from the cardinals Bellarmine and Baronius. It was in this city that he first conceived the plan of his "Gallia Christiana." He was afterwards nominated bishop of Chalons-sur-Saone; upon which event this prelate conferred a canonry of his cathedral upon his preceptor, and made him his archdeacon and grand vicar. The bishop was desirous of expressing his regard for our author, by collating him to other benefices; but M. Robert constantly refused any additional preferment. He discharged the duties of his appointments with the strictest fidelity, and died in the episcopal palace at Chalons in 1637, when about 73 years of age. The most considerable of his production is entitled "Gallia Christiana," &c. published at Paris in 1626, in folio, with an appendix, preface, and chronological tables of the popes and anti-popes, the Eastern and Western emperors, the kings of France and England, the councils of France, the indictions, &c. He left behind him materials for a second edition of this work, which were made use of by M. St. Marthe, whose new collections increased the work to three volumes folio. It was afterwards extended by the Benedictines to twelve volumes folio.

ROBERT DE VAUGONDY, a French geographer, was born at Paris in the year 1688. Little is known of his private history, but he became geographer to the king, and died at Paris in 1766. His works are "An Introduction to Sanson's Geography," 1743; "An Abridgment of the different Systems of the World," 1745; "Sacred Geography," 1746; "A Treatise on the Use of the Globes;" "A Portable Atlas;" and above all "Atlas Universel," published in 1756, consisting of 108 maps, upon a large scale, engraved with neatness and accuracy. He had a son, who for some time was the assiduous companion of his labours, and who assisted him in the "Atlas Universel," to which work is prefixed an historical preface, in six chapters, treating of the origin, progress, and present state of geography.

ROBERT DE BRIENNE, harper to Edward I. previous to his ascending the throne. The harp for many ages seems to have been the favourite instrument of the inhabitants of this island, whether under British, Saxon, Danish, or Norman kings. Many disgraceful circumstances are blazoned of the poor minstrels; it is therefore but just to relate those that redounded to their honour, and the Chronicle of Walter Heming furnishes an incident that well deserves to be recorded.

Edward I., according to this historian, about the year 1271, a short time before he ascended the throne, took his harper with him to the Holy Land; and this musician must have been a close and constant attendant on his master, for when Edward was wounded with a poisoned knife at Ptolemais, the harper, *citareda suus*, hearing the struggle, rushed into the royal apartment, and killed the assassin. This signal service from his bard did not, however, incline the monarch, afterwards, to spare his brethren in Wales. See Grey's Ode, "Ruin seize thee, ruthless king!"

ROBERT, *Herb*, in *Botany*. See GERANIUM.

ROBERT Bay, in *Geography*, a bay on the E. coast of Newfoundland.

ROBERT Bay. See CUL de SAC Robert.

ROBERTS'S Island, a small island on the Florida stream. N. lat. 24° 42'. W. long. 81° 33'.

ROBERTS'S Islands, a cluster of small islands in the Pacific ocean, the largest being eight miles long and from two to three wide, four others being very small; discovered in the

year 1792 by lieutenant Herget, commander of the *Dædalus* store-ship. S. lat. 7° 53'. E. long. 219° 50'.

ROBERTI, JOHN, in *Biography*, a celebrated professor of divinity among the Jesuits, was born in the year 1569. He commenced his academical studies at Liege, and continued them at Cologne, where, when he was twenty-two years of age, he entered into the society of Jesus. His proficiency in various branches of learning is highly commended, particularly in the belles-lettres, the several departments of theological learning, and ecclesiastical history. He was made professor of divinity, and created doctor of that faculty, at Mentz, discharging the duties of his post with great reputation, during a long succession of years, in that city, at Doway, at Treves, and at Wurzburg. He died at Namur in 1651, in the 82d year of his age. He was author of many works on theological subjects, of which the most important, and that which proves how deeply he was versed in scripture criticism, was entitled "Mystica Ezekielis Quadrige, hoc est, Evangelia Historiarum et Temporum Serie vinculata Gr. et Lat."

ROBERTON, in *Geography*, a township of Washington county, Pennsylvania, containing 899 inhabitants.

ROBERTSON, WILLIAM, in *Biography*, was born at Dublin in 1705, and received his grammar-learning under Dr. Francis Hutcheson, afterwards the celebrated professor of moral philosophy in the university of Glasgow. In the year 1722 young Robertson removed to that university, where he continued till the year 1725, when he was admitted to the degree of M. A. During this year there was a dispute between Mr. Sterling, the principal of the university, and the students, about the right of choosing the rector, in which Mr. Robertson took an active part, being selected by his fellow students to read their protest against the person, and his authority, who had been chosen rector in opposition to their wishes. Thus distinguished, he excited against himself the indignation of the principal, Mr. Sterling, and his rector, and was the only one of more than fourscore petitioners against whom they instituted proceedings. He was cited before the faculty, and after a trial which lasted several days a sentence of expulsion was pronounced. Mr. Robertson was satisfied of the justice of his cause, and presented a memorial on the subject to the duke of Argyle, through whose influence an appeal was made to the king, who appointed a commission to visit the university of Glasgow, with full powers to examine into and rectify all existing abuses. As a result of this enquiry, the right of electing their rector was restored to the students: the visitors on this occasion also, among whom was the earl of Hay, called the principal to a severe account for the public money which he had embezzled, and ascertained the right of the university to send two gentlemen, upon handsome exhibitions, to Baliol college in Oxford: they moreover annulled the expulsion of Mr. Robertson, and ordered that measure particularly to be recorded in the proceedings of the commission; declared the election of the rector, who had been named by the principal, to be void; and assembled the students, who immediately chose the son of lord Rofs to be their rector.

While the visitors were exercising their powers, Mr. Robertson remained at London, and on the return of lord Hay he introduced Mr. Robertson to Dr. Hoadly, the bishop of Winchester, who made him known to Dr. Wake, archbishop of Canterbury; and he was entertained with much civility by both these prelates. He had, from a thorough conviction of its importance, devoted himself to the clerical profession; but at present being too young to be admitted into orders, he employed himself, while in London, in visiting public libraries, attending lectures, and improving

himself as opportunity offered. As soon as he was old enough to receive ordination, he was nominated by Dr. Hoadly to the cure of Tallow, in the county of Carlow. Here he continued till he was of age for priest's orders, to which he was admitted on the 10th of November 1729, and on the next day he was presented by lord Carteret, then lord lieutenant of Ireland, to the rectory of Ravilly, in the county of Carlow, and to another rectory in the county of Wicklow. In 1728 he married Elizabeth, the daughter of major William Baxter, by whom he had twenty-one children.

Mr. Robertson first appeared as an author about the year 1738, by a pamphlet entitled "A Scheme for utterly abolishing the present heavy and vexatious Tax of Tythes:" the object of this work was to pay the clergy and improvers a tax upon land in lieu of tythes, and it excited so much attention, that several editions of it were called for in a short space of time. In 1739 Mr. Robertson received from lord Cathcart a deputation to be his chaplain; and in the year 1743 he obtained leave from his diocesan to nominate a curate at Ravilly, and to reside some time in Dublin for the education of his children. Immediately on his settlement in this city he was invited to the cure of St. Luke's parish, which he retained about five years, when he returned to Ravilly. While in that city he formed a scheme, jointly with Mr. Kane Percival, to raise a fund for the support of the widows and children of clergymen within the diocese of Dublin, which has since produced very happy effects. In 1758 he met with a severe affliction in the death of his wife, to whom he was most tenderly attached, but he sustained the loss with exemplary resignation to the will of God. Soon after this he found a new patron in Dr. Richard Robinson, who had been translated from the see of Killala to that of Ferns, and who presented to Mr. Robertson the first benefice which became vacant in his lordship's presentation. Before, however, he could be collated to it, he, for the first time, had the "Free and Candid Disquisitions relating to the Church of England, &c." put into his hands; and, by the perusal, he was led to entertain such doubts respecting some points to which he would be required to declare his assent, as made him defer his attendance on the bishop. At length he received a letter from his lordship, calling upon him to come immediately for institution. Upon this he wrote a very affecting letter to the prelate, in which he returned the most grateful thanks for his kindness, but said he could no longer conscientiously comply with the terms required by law to qualify him for such preferment. "In debating this matter with myself," says he, "besides the arguments directly to the purpose, several strong collateral considerations came in upon the positive side of the question. The straightness of my circumstances pressed me close; a numerous family, quite unprovided for, pleaded with the most pathetic and moving eloquence. And the infirmities and wants of age now coming fast upon me were urged feelingly. But one single consideration prevailed over all these—that the Creator and Governor of the universe, whom it is my first duty to worship and adore, being the God of truth, it must be disagreeable to him to profess, subscribe, or declare, in any matter relating to his worship and service, what is not believed strictly and simply to be true."

Mr. Robertson, though he refused to subscribe for the sake of preferment, did not feel it necessary to quit the church, and continued to perform the duties of parish priest; but from this time he omitted the reading of the Athanasian creed, and some other parts of the public service which appeared to him to countenance unscriptural tenets. Finding, however, that this mode of conduct gave offence to some per-

sons, he resigned his benefices in 1764, and in 1766 he published, by way of apology to his friends for what he had done, his learned and ingenious little work, entitled "An Attempt to explain the Words Reason, Substance, Person, Creeds, Orthodox, &c." to which he subjoined the letter written to his bishop, of which an extract has been given above. He now came to London, where he met with a very cordial and liberal reception from many excellent men, who generously contributed to his support. In the following year he presented a copy of his "Attempt, &c." to the university of Glasgow, and, in return, received a most obliging letter, accompanied with the diploma of D.D. In 1768 he was nominated to the mastership of the free grammar-school at Wolverhampton, in Staffordshire, by the company of Merchant Taylors; which, though honourable to the patrons, was not lucrative to the doctor, the salary being only 70*l. per ann.*, and this was, for some years, diminished by a pension of 40*l.* to a superannuated predecessor. Dr. Robertson was, however, satisfied, and through the kindness of his friends was prevented from wanting what was necessary to his support. At one time he received from an unknown hand a present of 500*l.*, and from various persons stated assistance was sent him. In 1772 he was chosen one of the committee of the society of clergymen, &c. employed to draw up, and present to the house of commons, a petition praying for relief from the obligation of subscription to the 39 articles. In the course of a few years he had the misfortune to lose all his children one after another; and he himself died in May 1783, in the 79th year of his age. Dr. Robertson was possessed of great learning and an excellent judgment; he had a fine imagination, and a temper regulated by the mild and amiable spirit of Christ; and in his address and manners he was at all times easy and cheerful. When he quitted the church he was probably of the Arian school, but in the latter years of his life he became a firm believer in the simple humanity of Christ. He was mentioned by Mr. Lindsey, a few months before his death, as "the aged and venerable father of Unitarian nonconformity of our own days;" and in another work the same writer says, "the example of an excellent person now living at Wolverhampton, Dr. Robertson, has been a secret reproach to me ever since I heard of it." See Lindsey's Apology for resigning the Vicarage of Catterick, his Historical View of the Unitarian Doctrine, and Dr. Disney's Communications to the Gent. Mag. 1783.

ROBERTSON, WILLIAM, D. D., a celebrated historian, was born in 1721, at Borthwick, in Mid Lothian, of which parish his father was then minister. He received the early part of his education at Dalkeith, under Mr. Leslie, a master of high repute. In 1733 he entered upon his academical studies at Edinburgh. After the completion of his course, he obtained a licence to preach in 1741, and in 1743 he was presented, by the earl of Hopetoun, to the living of Gladsmuir, in East Lothian. On this living, which was not more than 100*l. per ann.*, he contrived to educate his six sisters and a brother, who, about this time, were left orphans by the death of both their parents. Here also he displayed his zealous attachment to the cause of liberty, by his efforts, in the year of the rebellion, in favour of the house of Brunswick, which he carried so far as to quit, for a season, his parochial charge, and join the volunteers of Edinburgh. He became, in a short time, distinguished for his eloquence and good taste as a preacher; and, in 1755, a sermon which he delivered before the Society for propagating Christian Knowledge, and which was the only composition of that kind that he ever published, raised him very high as a pulpit orator. It passed through five editions, and was translated

translated into the German language. He had, some years previously to this, begun to take a part in the debates of the general assembly of the church of Scotland, and, as he possessed great talents for business, as well as the powers of a public speaker, he acquired an ascendancy in that body which, during a long period, gave him the lead in the ecclesiastical politics of the country. In 1754 a "Select Society" had been established in Edinburgh, among the first members of which are found many names that, in process of time, became highly distinguished in literature and public life. Among the number of these was that of Robertson, who was most assiduous in his attendance, and obtained from it an increase of reputation. In the mean time he was deeply engaged in the studies necessary for completing the plan of an historical work which he had formed soon after his first settlement as a minister, and having taken a journey to London for the purpose of making arrangements for the publication, his "History of Scotland during the Reigns of Queen Mary, and King James VI." made its appearance in the year 1759, in two vols. 4to. He had, previously to this, as appears by the title-page of the volume, obtained the degree of D. D. It was received by the public with general approbation and applause. The celebrated Hume, so far from betraying jealousy or envy at the appearance of a competitor for the historic palm, took the warmest interest in the success of the work.

The History of Scotland appears to have been the most popular of the author's works, and it had passed through fourteen editions during the life of the author. It had, in every respect, a favourable influence on his fortune, since the fame which he acquired by the publication was probably the cause of his rapid promotion. He had removed to Edinburgh, in consequence of a presentation to one of the churches of that city, while it was in the press; in the same year he was nominated chaplain of Stirling-castle; in 1761 he was appointed one of the king's chaplains in ordinary in Scotland, and in the following year he was elected principal of the university of Edinburgh. Two years after this he was appointed to the post of historiographer royal of Scotland, with the salary of 200*l. per ann.*, so that, at this period, he was the best benefited clergyman of his church. He was, moreover, the acknowledged head of the party which held the chief sway in a national church; and the period from his becoming principal of the university of Edinburgh, to his retreat from public life, was commonly denominated "Dr. Robertson's administration."

In the midst of the numerous avocations which his several offices created, he proceeded to collect materials for his "History of the Reign of the Emperor Charles V.," which he published in 1769, in three quarto volumes. This work was, like the former, received with high approbation; it increased his reputation both on account of the greater maturity of style to which he had attained, and of the more profound and varied research which the weight and copiousness of the theme led him to display. The introductory volume contained a view of the progress of society in Europe from the subversion of the Roman empire to the beginning of the sixteenth century, which was particularly admired, as presenting a masterly survey of the gradations by which the social institutions of antiquity have passed, through the barbarism of the dark ages, into all that characterizes the state of modern Europe. So highly pleased was Catharine, the empress of Russia, with the History of Charles V., that she conveyed her acknowledgments to the author in a present of a rich snuff-box set with diamonds.

In the year 1777, Dr. Robertson published his "History of America," in two vols. 4to., which, from the new views

of man and nature that it presents, and the magnificence and variety of its scenery, is perhaps the most entertaining of his productions. Either gratitude for the communications obtained from the Spanish court, or candour carried far beyond the bounds of moderation, led him to extenuate the cruelties that had been committed by that nation in their conquests in the new world, to a degree that brought upon him censure. The work proved so acceptable to the Spanish nation, that the author was unanimously elected a member of the Royal Academy of Madrid. In 1791 Dr. Robertson published "An Historical Disquisition concerning the Knowledge which the Ancients had of India, and the Progress of Trade with that Country, prior to the Discovery of the Cape of Good Hope." After this, Dr. Robertson's health began to decline, and in June 1793 he died at the age of 72. As an historian his style is pure, sweet, dignified without stiffness, singularly perspicuous, and often eloquent; the arrangement of his materials is skilful and luminous, his mode of narration is distinct, and his descriptions highly graphical; and he displays a sagacity in the development of causes and effects, and in his judgment of public characters and transactions, which is very remarkable in one who was brought up in retirement. "If," says one of his biographers, "there is less glow and ardour in his expressions of moral and political feelings, than some writers in a free country have manifested; there is, on the other hand, all the candour and impartiality which belongs to a cool temper, when enlightened by knowledge and directed by principle." To his private and social virtues the most liberal testimony has been given, even by those who were his opponents in church politics. See Dr. Dugald Stewart's Life of Principal Robertson.

ROBERTSON, JOSEPH, was born at Knipe, in Westmoreland, in 1726, and educated at Appleby school, from which place, in 1746, he went to Queen's college, Oxford, where he took his degree of M. A., and, on entering holy orders, he was presented to the vicarage of Hertford, in Hampshire. In 1764 he became an author, by contributing largely to the Critical Review, an occupation in which he continued more than 20 years. In 1770 he was presented to the rectory of Sutton, in Essex, and in 1779 to the vicarage of Horncastle, in Lincolnshire. In 1782 he published what he entitled "An Introduction to Polite Literature," a very small volume, and which cannot certainly deserve so high founding a title. It has been reprinted several times. It is a sort of spelling-book or primer, with good rules for pronunciation. The author was, however, so tenacious of his property, that he attacked, with much severity, the late Dr. Paley, for copying a part of it without acknowledgment, into a little piece intended for the use of Sunday schools. Dr. Paley's reply and defence is that of a gentleman and scholar, and must be quite satisfactory to the candid reader. Mr. Robertson's next piece, "An Essay on Punctuation," was published in 1785; it is a work of considerable merit, and has gone through several editions. In 1788 appeared his "Dissertation on the Parian Chronicle." Mr. Robertson published, in 1795, a new "Translation of Telemachus;" and in 1798 "An Essay on the Education of Young Ladies," which was followed by an "Essay on the Nature of English Verse." He died in 1802. See Gent. Mag. vol. lxiii. Monthly Mag. Meadley's Memoirs of Dr. Paley.

ROBERTSON'S County, in *Geography*, a county of America, in the district of West Tennessee, bordering N. on Kentucky, and containing 7270 inhabitants. It is watered by Cumberland and Red rivers.

ROBERVAL, GILES PERSONNE DE, in *Biography*, an excellent

excellent mathematician of the 17th century, was born at Roberval, a feignory belonging to his family, in the diocese of Beauvais, in the year 1602. In the course of his education he discovered a strong inclination towards the study of the mathematics, with which he made himself very conversant. When he was 30 years of age he obtained the professorship of mathematics in the college of Gervais, at Paris; and afterwards he contested, with other candidates, the succession to the vacant chair of Ramus, which he gained by the superiority of his powers in disputation. He succeeded Morin as mathematical professor at the college-royal, the duties of which office he performed with high reputation so long as he lived. He was chosen a member of the Royal Academy of Sciences in 1666, and communicated to that body some curious experiments on the Torricellian vacuum, which he made in the years 1647 and 1648. He invented two new kinds of balances, one of which was adapted to the weighing of air. Roberval died in 1675, at the age of 73. His chief works are "A Treatise on Mechanics," inserted in Mersenne's "Universal Harmony." A treatise "On the Mundane System," written in Latin, attributed to Aristarchus of Samos, but generally believed to be his own production. Besides these he contributed several papers to the Memoirs of the Academy of Sciences: such as "Experiments concerning the Pressure of the Air;" "Observations on the Composition of Motion, and on the Tangents of Curve Lines;" "The Geometrical Resolution of Plane and Cubic Equations;" "A Treatise on Indivisibles;" at the end of which he has explained a new method for the transformation of figures, to which Torricelli gave the name of "Robervallian Lines."

**ROBERVALLIAN LINES**, a name given to certain lines, used for the transformation of figures: thus called from their inventor M. de Roberval.

These lines bound spaces infinitely extended in length, which are nevertheless equal to other spaces terminated on all sides.

The abbot Gallois, in the Memoirs of the Royal Academy, anno 1693, observes, that the method of transforming figures, explained at the latter end of M. de Roberval's Treatise of Indivisibles, is the same with that since published by Mr. James Gregory, in his Universal Geometry, and afterwards by Barrow, in his *Lectiones Geometricæ*; and that, by a letter of Torricelli, it appears that Roberval was the inventor of this manner of transforming figures, by means of certain lines, which Torricelli therefore called *Robervallian lines*.

He adds, that it is highly probable, that J. Gregory first learned the method in the journey he made to Padua in 1668; the method itself having been known in Italy from the year 1646, though the book was not published till the year 1692.

This account Dr. David Gregory has endeavoured to refute, in vindication of his brother. His answer is inserted in the *Phil. Trans.* an. 1694, and the abbot has rejoined in the French Memoirs of the Academy.

**ROBESON**, in *Geography*, a county of North Carolina, in Fayette district, bounded S. by the state of South Carolina. It contains 7528 inhabitants. The chief town is Lambertson.—Also, a township of Lancaster county, Pennsylvania; containing 1807 inhabitants.

**ROBESPIERRE**, MAXIMILIAN ISIDORE, in *Biography*, was born at Arras in 1759. His father, a barrister, having ruined himself by his prodigality, left France before the revolution, established a school at Cologne, where, however, he did not remain long, and he went from thence into England, and afterwards to America. Deserted by his fa-

ther, and his mother dying when he was only nine years old, he was taken under the patronage of the bishop of Arras, M. de Conzie, who caused him to be sent to the college of Louis le Grand, where he was taken on the foundation. From a very early age he was noticed for his love of independence; he was however timid, and in his temper gloomy and unfociable. He was extremely assiduous in his studies, and gave hopes of talent, that were not realized in after-life. In 1775, when Lewis XVI. made his entry into Paris, he was chosen by his fellow students to present to that prince the homage of their gratitude. Becoming a barrister in the council of Artois, he obtained a place in the academy of Arras. In the year 1789 he took an active part in all the revolutionary meetings, and was appointed a deputy from the province of Artois to the States-General. He manifested but little talent as an orator or legislator, but attached himself to Neckar, and then to Mirabeau, during the heights of their popularity; but when they became less caressed by the people, Robespierre was the first to notice the difference, and deserted them for some other leader. The first time that he made himself at all remarked in the constituent assembly, was on the 20th of July 1789, when he opposed the scheme of martial law; and from that period, says his biographer, "he endeavoured to legitimize insurrection." By courting the people, and displaying a determined hostility to the royal prerogatives, he laid the foundation for future influence in the democratic party; and it has been considered a very remarkable circumstance, in connection with his future conduct, that the most frequent topic of his declamation was the injustice of capital punishment in any case.

After the dissolution of the constituent assembly, followed by the election of the legislative body, the members of which being all new, Robespierre's chief theatre of action was the Jacobin club, at which he was the principal speaker. He also published a weekly paper, entitled "Le Defenseur de la Constitution." He now took a decided part with the republicans, though it does not appear that he was an actor in the insurrection of the 10th of August, or in the prison-massacres of September. In the new assembly, which met in September 1792, he was returned a member for the city of Paris, and he soon became the head of the party called the Mountain, which was opposed to the followers of Brissot, who then possessed the ministerial power. He was now charged with the desire of making himself dictator, but his party in the senate was too powerful for his accuser to carry the point, and the assembly passed a decree to print and circulate the speech which he made in justification of himself. By this he became still more popular, and his subsequent exertions to bring the unfortunate king to trial, augmented his influence with the democratic part of the nation. Soon after the execution of Lewis, Robespierre, assisted by Danton and Marat, gained a most decided supremacy in the national convention, and the period commenced which has been emphatically, but justly, denominated the reign of terror. The Brissotines, to the number of twenty-one, were accused, condemned, and guillotined. After them followed the queen, the duke of Orleans, and other members of the royal family. The scaffold daily streamed with the blood of nobles, priests, and all who by character and condition could be suspected of being attached to the ancient government. In some of the provinces, massacres were perpetrated against whole orders of men, without distinction: the levelling principle was extended to all superiority of science and talent, and it seemed Robespierre's object to bring back an age of barbarism. At length his own confederates, Danton, Desmoulins, Fabre d'Eglantine, and others, were brought to the

block. In the midst of all these horrors he exhibited a festival, in which the existence of the Supreme Being was solemnly recognised; and as the restorer of religion, he appointed days for public worship.

The reign of terror was now become too intolerable to be endured. No man was safe from a tyrant whose bloody disposition seemed to grow with the acts of cruelty which it generated, and who had established such a system of domestic treachery, as destroyed the confidence of society, and subjected every individual to accusation. He lost his popularity, and a decree of the convention was passed against him: in the act of arresting him two pistols were fired, by which he was wounded in the head and the under-jaw. He endured in silence the pain of his wounds, and the upbraiding of his foes, and was carried to the same dungeon which he had made to many the passage to death. On the next day, after being taken, with his accomplices, before the revolutionary tribunal, he was led, July 28, 1794, to execution, amidst the acclamations and curses of thousands of spectators. Such was the well-merited end of Robespierre, in the 36th year of his age. Although a concurrence of circumstances enabled him to act a considerable part in the revolution, he was not one of the superior figures in point of abilities and force of character. Natural reserve, cunning, habitual dissimulation, and a total want of feeling, carried him through difficulties which might have overwhelmed a greater man; but as he never made a friend, and was unsupported by native courage, he sunk under the first serious opposition. He was regarded as incorruptible, and never accumulated money: nevertheless, he always took care to open the path of honour and wealth to his own creatures, and especially to his rivals, in order that he might have an additional method of ruining them. Upon the whole, he has left a name more the object of horror and detestation, than that of any other among the personages of the same awful drama.—Ann. Register. Lives of Remarkable Characters, who have distinguished themselves in the French Revolution. Biog. Anec. of the Founders of the Fr. Rev.

**ROBIA HERBA**, in *Botany*, a name given by Paulus Ægineta, and many others, to a plant used in dyeing.

The near resemblance of the name to the word *rubia*, has made many conclude that it was the *rubia*, or madder, which they have meant by it; but they have taken care in their writings to distinguish it from that plant, and it is plainly the *geniella tinctoria*, or dyer's weed, that they meant by the *robia herba*. They say it was used to dye yellow, and that it was also a custom to stain the hair with it.

These are the properties recorded of the *cynene* and *aconemenium* of the Greeks, and the *lutum*, or *lutea herba*, of the Latins, which were names of the *geniella tinctoria*. Pliny says, that the *lutum* had leaves like flax, and flowers like broom, which is exactly the case with the *geniella tinctoria*, but by no means agrees with the *glaitum* or woad.

**ROBISSOU**, in *Geography*, a town of Austrian Poland; 22 miles S. of Chelm.

**ROBIGALIA**, or **RUBIGALIA**, in *Antiquity*. See **RUBIGALIA**.

**ROBILLANTE**, in *Geography*, a town of France, in the department of the Stura; six miles S. of Coni.

**ROBIN**, or, as it is more usually called, *Robin red-breast*, *Rubecula*, in *Ornithology*. See **RED-BREAST**.

**ROBIN**, *Ragged*, in *Botany*. See **CAMPION**.

**ROBIN**, *Wake*. See **WAKE ROBIN**.

**ROBINAL**, in *Geography*, a town of Mexico, in the province of Vera Paz; containing 800 inhabitants; 40 miles S.S.W. of Vera Paz.

**ROBIN-HOOD'S BAY**, a bay on the E. coast of Newfoundland, frequented by small vessels.

**ROBINIA**, in *Botany*, commemorates John Robin, botanist to Henry IV. and Louis XIII. of France, who published a catalogue of his own garden, which has gone through several editions. He also supplied descriptions to Valler's figures. A popular French author, who calls himself M. de Vigneul-Marville, but whose real name was d'Argonne, in his *Melanges*, stigmatizes Robin for his greedy and selfish love of flowers, the more curious kinds of which he would rather destroy, than communicate to his friends. In allusion to this, and to a report of his being an eunuch, he was addressed in a bitter Latin satire, as by nature an enemy to all propagation. De Theis, nevertheless, speaks of Vespasian Robin as his son. They published conjointly a botanical *Enchiridion*, or manual, and one of them introduced into the French gardens, from American seeds, that species of *Robinia* called *Pseudo-acacia* by Tournefort, who under that name founded the present genus.—Linn. Gen. 378. Schreb. 501. Willd. Sp. Pl. v. 3. 1131. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 323. Pursh v. 2. 487. Juss. 358. Lamarck Illustr. t. 606. Gærtn. t. 145. (*Pseudoacacia*; Tourn. t. 417. Caragana; Lamarck Dict. v. 1. 615. Illustr. t. 607. Juss. 358.)—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosa*, Juss.

Gen. Ch. *Cal.* Perianth interior, of one leaf, small, bell-shaped, four-cleft; the three lower teeth narrowest; the upper one twice as broad, with a broad shallow sinus; all of equal length. *Cor.* papilionaceous. Standard roundish, large, spreading, obtuse. Wings oblong-ovate, distinct, each with a very short blunt appendage. Keel nearly semiorbicular, compressed, obtuse, the length of the wings. *Stam.* Filaments diadelphous, one simple, the other nine combined, ascending towards the extremity; anthers roundish. *Pist.* Germen cylindrical, oblong; style thread shaped, bent upwards; stigma terminal. *Peric.* Legume large, long, gibbous, compressed. *Seeds* few, kidney-shaped.

Ess. Ch. Calyx four-cleft; the upper segment divided. Standard roundish, reflexed. Stamens in two distinct sets. Legume elongated, gibbous, of one cell, with many seeds.

Obs. Jussieu and Lamarck distinguish their genus *Caragana*, by its smooth abrupt stigma, and a somewhat cylindrical inflated legume. The former adds, that the leaves are abruptly pinnate, without the terminal leaflet seen in *Robinia*. Yet Lamarck's plates do not confirm all these distinctions. Linnæus describes the stigma as downy, and yet in his Syst. Veg. ranges *Robinia* among genera which want that character. In fact the style, rather than the stigma, is downy.

1. *R. Pseudoacacia*. Common Acacia, or Robinia. Linn. Sp. Pl. 1043. Willd. n. 1. Ait. n. 1. Pursh n. 1. "Schmidt Arb. t. 32." (*Pseudoacacia*; Duham. Arb. v. 2. 188. n. 1. t. 42.)—Partial stalks single-flowered. Leaves pinnate, with an odd leaflet. Stipulas spinous. Legumes smooth, compressed.—Native of dry fertile ridges, on the mountains of North America, from Canada to Carolina, flowering in May and June. *Pursh.* Cultivated here, by the elder Tradescant, before 1640. *Parkinson.* This is a large and handsome tree, of quick growth, beautiful in foliage, and highly ornamental, when laden in summer with bunches of white sweet-scented flowers, resembling those of the *laburnum* in size and position. The branches are liable to be shivered off by our autumnal storms. Mr. Pursh says, "the wood is almost incorruptible, and particularly calculated for posts of gates and fences." The leaves are deciduous

## ROBINIA.

deciduous, a span long, of a peculiarly pleasant light green, consisting of many elliptical, opposite or alternate, stalked leaflets. The short awl-shaped *stipulas* become rigid spines. *Legumes* pale, wavy, compressed, two or three inches long.

2. *R. viscosa*. Clammy Robinia. Willd. n. 2. Ait. n. 2. Pursh n. 2. Venten. Jard. de Cels, t. 4. (*R. glutinosa*; Curt. Mag. t. 560. *R. Pseudoacacia* var. Sm. in Abbot's Inf. of Georgia, v. 1. 37. t. 19.)—Partial stalks single-flowered. Leaves pinnate, with an odd leaflet. Branches and legumes clothed with viscid glands.—Native of the banks of rivers in South Carolina, especially the Savannah, flowering in June and July; and said to have been introduced into our gardens, where it is quite hardy, by Mr. R. Whitley, in 1797. This species not being known to us when Abbot's Infests of Georgia were published, was, in that work, mistaken for a red-flowered variety of the foregoing. The whole tree is of a smaller size than that species, and distinguished by its dark red viscid branches. The flowers are variegated with pink and white. *Stipulas* forming straighter spines. The creeping roots are said, by Mr. Pursh, to be troublesome in small plantations. Hence, however, our gardeners propagate the tree the more easily by cuttings of the root, instead of grafting this species on the more brittle *Pseudoacacia*.

3. *R. violacea*. Violet Robinia. Linn. Sp. Pl. 1044. Willd. n. 3. Ait. n. 3. Jacq. Amer. 210. t. 177. f. 49.—Partial stalks two-flowered. Calyx but slightly toothed. Leaves pinnate, with an odd leaflet. Branches without thorns.—Found by Jacquin in bushy places about Carthage in South America, flowering in July and August. Miller cultivated this plant, but it is now unknown in our stoves. Jacquin describes it about twelve feet high, erect, with shining leaves, whose leaflets are about six pair, stalked, ovate, obtuse, emarginate, two inches long. *Clusters* axillary, half a foot in length; their partial stalks short, numerous, each bearing two flowers, which resemble our sweet violet in scent as well as colour.

4. *R. striata*. Striated-leaved Robinia. Willd. n. 4.—“Partial stalks single-flowered. Leaves pinnate, with an odd leaflet; downy beneath. Branches without thorns.”—Gathered by Bredemeyer, on open sunny hills in the Caraccas. A large shrub, with pale, unarmed, warty branches. Leaves half a foot long, composed of from fifteen to twenty-five oblong, pointed leaflets, each an inch in length, striated with veins; shining above; covered with close-pressed hairs beneath. *Stipulas* lanceolate, deciduous. *Clusters* simple, shorter than the leaves, downy, as well as the calyx. *Bractees* awl-shaped, very short. *Corolla* yellow, Willdenow.

5. *R. hispida*. Hairy Robinia, or Rose Acacia. Linn. Mant. 101; excluding the reference to Jacquin. Willd. n. 5. Ait. n. 4. Pursh n. 3. Curt. Mag. t. 311. (*R. foliis impari-pinnatis; foliolis ovatis, ramis pedunculisque hispida; Mill. Ic. 163. t. 244. Pseudoacacia hispida, floribus roseis; Catesb. Carol. v. 3. 20. t. 20.*)—Branches, calyx, and flower-stalks hispid. Thorns none. Leaves pinnate, with an odd leaflet. Partial stalks single-flowered.—Native of mountains in Virginia and Carolina. Hardy with us, flowering from May to September, being a very ornamental shrub, on account of its large pink copious blossoms, enhanced, like a moss rose, by the brown bristly covering of the stalks and calyx. Pursh notices a taller and less hispid variety.

6. *R. sepium*. Hedge Robinia. Willd. n. 6. Jacq. Amer. 221. t. 179. f. 101. Swartz Ind. Occ. v. 3. 1258.—Partial stalks mostly two-flowered. Leaves pinnate, with

an odd leaflet, pointed. Thorns none.—Native of the banks of rivers, in the recesses of mountains of the West Indies, flowering about March and April. A tree twenty or thirty feet high, with long, lax, spreading branches. The leaflets differ from those of *violacea*, n. 3, in being pointed, not emarginate. *Clusters* rather drooping, of numerous purple flowers; their stalks smooth.

7. *R. squamata*. Scaly-branched Robinia. Willd. n. 7. “Vahl Symb. v. 3. 88. t. 69.”—Partial stalks single-flowered. Leaves pinnate, with an odd leaflet, spinous-pointed. *Stipulas* spinous.—Native of the island of St. Thomas. Branches round, smooth, leafy towards the ends, scaly below the leaves; bearing smaller ones scarcely an inch long, clothed with four rows of imbricated, ovate, pointed scales. Leaflets about nine pair, oval or roundish, smooth and shining on both sides, the midrib of each extended into a terminal spine. *Stipulas* permanent, hardening into thorns. *Clusters* axillary, downy, of four or five distant flowers. *Bractees* small, linear. *Calyx* smooth, with lanceolate segments. *Legume* compressed, linear, occasionally contracted here and there, as if jointed.

8. *R. uliginosa*. Swamp Robinia. Willd. n. 8.—“Partial stalks three-flowered. Leaves ternate, oblong, pointed. Branches twining, without thorns.”—Native of the East Indies; communicated to Willdenow by Dr. Roxburgh. The branches are described as round and smooth. Leaflets an inch and half long, pointed, smooth. *Clusters* from the old branches, three inches in length. Flowers apparently white.

9. *R. scandens*. Climbing Robinia. Willd. n. 9. (*R. Nicou; Aubl. Guian. v. 2. 771. t. 308.*)—Partial stalks single-flowered. Leaves pinnate, with an odd leaflet, oval, pointed, smooth. Branches twining, without thorns.—Native of the woods of Guiana, flowering in June. A twining shrub, of lofty growth, crowning the neighbouring trees with its leafy branches, and purple blossoms. The leaflets are usually seven, each about four inches long. Flowers in axillary clusters. *Legume* compressed, thick-edged, smooth, measuring about two inches. The natives of Guiana beat the water with fresh cut twigs of this shrub, by which means the fish are intoxicated, and floating insensible near the surface, are easily caught.

10. *R. tomentosa*. Downy Robinia. Willd. n. 10. (*R. Panacoco; Aubl. Guian. v. 2. 768. t. 307.*)—Partial stalks single-flowered. Leaves pinnate, with an odd leaflet, elliptical, pointed, coriaceous; somewhat downy beneath; their common stalk rough. Stem arboreous, without thorns.—Found by Aublet in the woods of Cayenne and Guiana, being one of the largest trees of those countries. The trunk is 60 feet or upwards in height, and usually a yard in diameter; its base subdivided above ground, so as to form cavities six or eight feet wide, affording shelter to wild beasts. The head consists of strong and widely extended branches, which when young are clothed, like the main stalks of the leaves, with red or rusty down. The leaflets are from eleven to fourteen, various in size, from three to eight inches long, veiny and wrinkled; smooth above; more or less hairy or downy beneath. *Stipulas* deciduous. *Clusters* at the ends of the branches. Flowers reddish. *Legume* two inches long, half-lanceolate. The bark of the tree, when wounded, distils a copious resinous balsam. The wood is almost incorruptible, Aublet having observed polts, partly in the ground, which were quite found, though said to be above 60 years old.

11. *R. florida*. Flowery Robinia. Willd. n. 11. “Vahl Symb. v. 3. 89. t. 70.”—Stalks simple, single-flowered. Leaves abruptly pinnate, smooth; their common

## ROBINIA.

stalks unarmed. Stipulas lanceolate, permanent, flexible. Calyx nearly entire.—Native of the West Indies. A very beautiful *shrub*, entirely covered with large purplish *flowers*, four or five from each bud, on simple capillary *stalks*, before the leaves appear. *Branches* round, smooth, dotted, purplish-grey. *Lower leaves* from the flowering buds of the preceding year, usually two or three together, the length of the finger; *upper ones* on the young branches solitary, alternate, half as long again; leaflets stalked, opposite, oblong, smooth, veiny, pointed, the uppermost rather smallest: common footstalk without any terminal spine. Stipulas lanceolate, small, thin, flexible, permanent. Calyx cup-shaped, nearly entire, finely downy. Corolla large; its claws the length of the calyx. Germen smooth. *Vahl*.

12. *R. polyantha*. Many-flowered Robinia. Swartz Ind. Occ. v. 3. 1260.—Stalks simple, single-flowered. Leaves abruptly pinnate; hoary beneath; their common stalks unarmed. Stipulas awl-shaped, close-pressed, permanent. Calyx with linear teeth.—Native of thickets on the mountains of Hispaniola. A *shrub*, about six feet high, erect, with copious *branches*, destitute of dots; greyish and downy when young. *Flowers* pale purple, three or four from each bud, appearing mostly before the leaves, as in the last, from which this species chiefly differs in the smaller size of every part, and in the teeth of its *calyx*, which are nearly, if not entirely, wanting in *R. florida*. Swartz.

13. *R. Caragana*. Caragana Robinia, or Siberian Pea-tree. Linn. Sp. Pl. 1044. Willd. n. 12. Ait. n. 5. "Schmidt Arb. t. 33." (R. Altagana; Pall. Ross. v. 1. p. 1. 68. t. 42, the middle figure only.)—Stalks simple, single-flowered, many together. Leaves abruptly pinnate, of about four pair of elliptical leaflets; their common stalks unarmed. Stipulas thorny. Legume cylindrical.—Native of Siberia. Cultivated by Miller in 1752. Hardy in our gardens, flowering in April and May. The *stem* forms a bushy *shrub*, producing from each bud numerous large yellow *flowers*, on long simple stalks, accompanied by several abruptly pinnated, nearly smooth, *leaves*, which become alternate on the protruding *branches*. The *leaflets* are mostly alternate, elliptical or obovate, hardly an inch long. The *stipulas* change into straight awl-shaped thorns.

14. *R. Altagana*. Sand Robinia. Willd. n. 13. Ait. n. 6. L'Herit. Stirp. 159. t. 76. Pall. Ross. v. 1. p. 1. 69, the small variety, t. 42, the lateral figures.—Stalks simple, single-flowered, solitary. Leaves abruptly pinnate, of about eight pair of obovate, or inversely heart-shaped, leaflets; their common stalks unarmed. Stipulas thorny. Legume compressed.—Native of sandy ground in Siberia. Introduced into England by Mr. Bell, in 1789. Differs from the last, of which Pallas made it a variety, in its more humble size, emarginate, numerous, and hoary *leaflets*; solitary *flowers*; and especially its compressed *legume*. These two species, so nearly akin, prove the supposed generic distinction of the cylindrical and compressed *legumes*, asserted by Lamarck to be of no avail, in a natural point of view, for the purpose of dividing *Robinia* into two genera.

15. *R. jubata*. Bearded Robinia. Willd. n. 14. Ait. n. 7. "Pall. in Nov. Act. Petrop. v. 10. 370. t. 6."—Stalks simple, single-flowered. Leaves abruptly pinnate, of numerous pairs of lanceolate, downy leaflets; their common stalks thread-shaped, spinous, permanent, reflexed. Branches villous.—Found near lake Baical in Siberia, from whence it was imported by Mr. Bush, in 1796. This is a small *shrub*, scarcely two feet high, with villous *branches*, assuming a very peculiar aspect in consequence of its numerous, reflexed, permanent, hardened and spinous *common*

*footstalks*. The *leaflets* are narrow. *Flowers* purplish. *Legumes* cylindrical, hard, reddish-brown.

16. *R. tragacanthoides*. Tragacanthine Robinia. Willd. n. 15. "Pall. in Nov. Act. Petrop. v. 10. 371. t. 7."—Stalks simple, single-flowered. Leaves abruptly pinnate, of two pair of oblong-lanceolate, silky leaflets; their common stalks spinous and permanent, as well as the stipulas. Legume downy, somewhat compressed.—Native of granite rocks in Siberia, beyond lake Baical. A small *shrub*, very much branched. *Branches* downy, armed with strong, recurved, stipulaceous *spines*. *Leaflets* small, tapering at each end, tipped with terminal, solitary thorns. *Flowers* yellow. *Legume* cylindrical, slightly compressed. Willd.

17. *R. spinosa*. Thorny Robinia. Linn. Mant. 269. Willd. n. 16. Ait. n. 8. "Schmidt Arb. t. 36." (R. ferox; Pall. Ross. v. 1. p. 1. 70. t. 44.)—Stalks single-flowered, very thort. Leaves abruptly pinnate, of about three pair of wedge-shaped smooth leaflets; their common stalks spinous and permanent, as well as the stipulas. Legume cylindrical. Native of moist gravelly vallies, as well as of dry sandy hills, in Siberia. Hardy in our gardens, flowering in April and May. Pallas reports, that it is frequent about Pekin in China, where, being fixed with clay on the tops of walls, it serves to keep off intruders. The long strong *thorns*, formed by the hardened *footstalks*, render the bushes of this species excellent for hedges. The *stems* are as tall as a man, much branched. *Leaflets* oblong-wedge-shaped, hardly an inch in length. *Flowers* yellow, axillary, either solitary or two or three together, each on a simple *stalk* not half the length of its *calyx*.

18. *R. Halodendron*. Salt-tree Robinia. Pall. It. v. 2. append. 741. t. W. Ross. v. 1. p. 1. 72. t. 46. Linn. Suppl. 330. Willd. n. 17. Ait. n. 9. Curt. Mag. t. 1016.—Stalks three-flowered. Leaves abruptly pinnate, of two pair of silky leaflets; their common stalks spinous and permanent. Legume inflated.—Found by Pallas, in dry salt fields, about the river Irtyz, in Siberia. The late Dr. Pitcairn is mentioned as having first imported it in 1779. This *shrub* is hardy with us, but seldom blossoms, which is much to be regretted on account of its beauty. Its thorny habit nearly accords with the foregoing; but the *leaflets* are fewer, larger, and silky, of a glaucous hue. *Corolla* of a delicate rose-colour. *Legume* ovate, inflated, an inch long, scarcely less different from the *Caragana* tribe, than from the original *Robinia*; yet no person who attends to natural genera could think of separating this plant from the last.

19. *R. Chamissoi*. Shining Robinia. L'Herit. Stirp. 161. t. 77. Willd. n. 18. Ait. n. 10.—Stalks single-flowered. Leaves abruptly pinnate, of two pair of obovate smooth leaflets; their common stalks spinous. Stipulas awl-shaped, spinous, permanent. Branches decumbent.—Supposed to be a native of China. It has long been cultivated in the French gardens, and was sent to Kew, in 1773, by Mons. Richard. The shrub is hardy, flowering in May and June. The *stem*, at first erect, throws out long decumbent *branches*. *Leaves* green, smooth and shining; each leaflet tipped with a small bristly point. *Flowers* large, on long, solitary, simple *stalks*, pendulous, yellow; the disk of their *standard* at first green, afterwards deep red. The young *legume* is cylindrical, but we have never seen it full-grown. The *footstalks*, though spinous, are less hard and permanent than in many of the other species.

20. *R. frutescens*. Bush Robinia. Linn. Sp. Pl. 1044. Willd. n. 19. Ait. n. 11. Pall. Ross. v. 1. p. 1. 69. t. 43.—Stalks single-flowered. Leaves of four, obovate, smooth, bristle-pointed, equal-stalked leaflets. Branches ascending.—Native of hills in the temperate parts of Siberia. Cultivated

vated by Miller in 1752; flowering in the spring. The *stem* is branched, bushy, and erect, various in height, from two to eight or nine feet. *Leaves* different from all the foregoing, consisting of four, nearly equal, obovate *leaflets*, each on its own short partial stalk, at the summit of a rigid, spinous-tipped, *common footstalk*, not a quarter the length of the leaflets. *Stipulus* lanceolate, oblique, combined with the common footstalk, and at length hardened with it into a three-branched divaricated spine. *Flowers* yellow, their simple solitary stalks longer than the leaves. The *foliage* varies greatly in luxuriance, according to circumstances. The *legume* is cylindrical.

21. *R. pygmaea*. Dwarf Robinia. Linn. Sp. Pl. 1044. Willd. n. 20. Ait. n. 12. Pall. Ross. v. 1. p. 1. 71. t. 45. (*Aphalatus frutescens minor angustifolius, cortice aureo*; Amm. Ruth. 204. t. 35).—Stalks single-flowered. Leaves of four linear-lanceolate, spinous-pointed, nearly sessile leaflets.—Native of rocky hills in many parts of Siberia. Cultivated by Miller in 1751; flowering in the spring. This has much affinity to the last, but the narrow *leaflets* and their spinous points, as well as the more evident and pungent thorns of their short *common footstalk* and *stipulas*, readily distinguish it. The *flowers* are yellow. *Leaves* often more or less silky or hairy.

*R. mitis*, Linn. Sp. Pl. 1044, is referred by Willdenow to *Dalbergia*, under the name of *arborescens*; Sp. Pl. v. 3. 901. Ait. H. Kew. v. 4. 248. This is *Pongamia glabra*, Venten. Malmaif. t. 28; an East Indian tree, of lofty growth, which has not yet blossomed in our stoves. Ventenat saw its flowers at the garden of Malmaison. The *calyx* is purple; *petals* white. *Legume* ovate, pointed, thick and woody.

We are not acquainted with *R. amara* and *flava* of Loureiro, Coelinch. 455, 456, nor dare we adopt them without examination.

ROBINIA, in *Gardening*, comprises plants of the hardy, deciduous, tree and shrub sorts, with tender kinds for the stove. The species cultivated are mostly these: the false or common acacia (*R. pseudo-acacia*); the rose acacia, or robinia (*R. hispida*); the Siberian abrupt-leaved robinia (*R. caragana*); the shrubby robinia (*R. frutescens*); the dwarf robinia (*R. pygmaea*); the thorny robinia (*R. spinosa*); the ash-leaved robinia (*R. violacea*); and the smooth Indian robinia (*R. mitis*).

The first sort grows very fast whilst young, so that in a few years from seed, the plants rise to eight or ten feet high, and it is not uncommon to see shoots of this tree six or eight feet long in one summer; the branches are armed with strong crooked thorns. But there is a variety which has no thorns on the branches, but which is easily known at first sight by its peculiar appearance. And the echinated, or prickly-podded American false acacia, in which the pods are much shorter, and closely beset with short prickles, but in other respects agrees with the common sort.

The sixth species, on account of the length and toughness of the branches, and its large stout thorns, is admirably adapted to form impenetrable hedges, and is sufficiently hardy to bear our climate.

*Method of Culture*.—The first six hardy sorts are all capable of being raised from seeds, cuttings, layers, and suckers; but the seed method is said to afford the best plants.

The seeds should be sown about the end of March or beginning of the following month, on a bed of light mould, being covered to the depth of about half an inch. In the first sort and varieties the plants mostly appear in the course of six or eight weeks; but in the other kinds often not till the

next spring. They should be well weeded and watered, and when sufficiently strong, be set out in the spring or autumn in nursery-rows, for two or three years, in order to remain, to have proper growth for final planting out. The cuttings should be made from the young shoots, and be planted out in the beginning of autumn, in a shady border, where the soil is mellow. They are mostly well rooted in the course of a twelvemonth, when they may be removed into nursery-rows as above. The layers should be made from the young wood, being laid down in the autumn, when, in the course of the year, they mostly become well rooted, and may be taken off and planted out in nursery-rows, as the seedling plants. And the suckers, which are produced in plenty from the two first sorts, may be removed in the early autumn or spring, and be planted out in nursery-rows or in beds, to be afterwards removed into them.

The two last, or tender sorts, may likewise be raised from seeds and cuttings, but they must be sown and planted in pots filled with good mould, to have the assistance of a hot-bed in the stove, by being plunged in it. When the plants have attained a little growth, they should be shaken out of the pots, and planted separately in small pots, filled with the same sort of earth, plunging them in the tan-bed, affording due shade till well rooted, managing them afterwards as other tender stove plants. And as the plants are moist tender while young, they should therefore be kept in the stove tan-bed till they have acquired strength, when they may be preferred in the dry stove, with a temperate heat in winter, and be exposed in the open air in summer, in a warm sheltered situation, when the weather is fine.

It may be noticed that the hardy sorts have a fine effect in the border clumps and other parts of pleasure-grounds, and the tender kinds afford variety in the stove-collections.

ROBINS, BENJAMIN, in *Biography*, a celebrated mathematician, was born at the city of Bath in the year 1707. His parents were in very low circumstances, and utterly unable to give their son much education. His genius, however, strongly urged him to the pursuit of knowledge; he became his own instructor, and made an early and surprising progress in various branches of literature and science, particularly in the mathematics. He came to London under the patronage of Dr. Pemberton; and at the age of 20, he gave a demonstration of the last proposition of Newton's *Treatise on Quadratures*, which was so ably performed, that it was thought deserving a place in the *Philosophical Transactions* for the year 1727; and towards the close of the same year he was admitted a member of the Royal Society. In the course of the following year he embraced an opportunity of offering to the public a specimen of his acquaintance with natural philosophy. The Royal Academy of Sciences at Paris, among their prize questions in 1724 and 1726, had asked for a demonstration of the laws of motion in bodies impinging on one another. On this occasion, John Bernouilli appeared in the list of candidates, but did not obtain the reward. He felt himself aggrieved, and appealed to the learned world, by publishing his demonstration in 1727. In the following year, Mr. Robins published a confutation of Bernouilli's performance, which was allowed to be unanswerable. Mr. Robins, about this time, began to take pupils, professing to teach the mathematics only; yet he frequently assisted them with instruction and advice on other subjects, for which he was well qualified, by the rich stores of knowledge with which his mind was furnished. After some time he abandoned the laborious business of education, and devoted his attention to subjects which required more exercise. Among other things, he made many experiments in gunnery, from a belief that the

resistance of the air had a much greater effect on swift flying projectiles than was generally supposed. He likewise directed his attention to the mechanic arts, such as the construction of mills, the building of bridges, draining of fens, rendering rivers navigable, and the making of harbours. The art of fortification, likewise, very much engaged his thoughts: with this view he took pains to inspect all the principal strong places in Flanders, during some journeys which he made on the continent with persons of distinction. On his return, he undertook a defence of the doctrine of fluxions, as laid down by sir Isaac Newton, in opposition to the objections brought against it by the learned bishop Berkeley. In 1735 Mr. Robins published "A Discourse concerning the Nature and Certainty of Sir Isaac Newton's Method of Fluxions and of prime and ultimate Ratios." On the same subject he wrote two or three other pieces.

In the year 1739 he published, without his name, three pamphlets on political topics, and on the popular side of the question; and so highly did they raise the author in the estimation of the patriotic party, that when a committee of the house of commons was appointed to examine into the conduct of sir Robert Walpole, he was chosen their secretary. In 1742 Mr. Robins published a small treatise, entitled "New Principles of Gunnery;" containing the result of many experiments, by which he discovered the force of gunpowder, and the difference in the resisting power of the air to swift and slow motions. From which it appeared, that the opposition of that medium to bullets and shells, discharged from cannon and mortars, far exceeded what was generally imagined; and that the track which their motion described differed from that of a parabolic line, to a degree unsuspected by any who had written expressly on the subject, from the time of Galileo. This publication was undertaken to demonstrate his own superiority, as a man of talents, over a successful competitor, Mr. Muller, for a situation in the Royal Military Academy at Woolwich. Some time after the publication of this work, a paper having been admitted into the Philosophical Transactions, containing experiments intended to invalidate some of Mr. Robins's opinions, he thought proper, in an account which he gave of his book in the same Transactions, to take some notice of those experiments. In consequence of this, several dissertations of his on the resistance of the air were read, and experiments to confirm his doctrine were exhibited before the Royal Society, in the year 1746-7; for which he was presented with the annual gold medal by that society. His reputation was now so high, that he was invited by the prince of Orange to assist in the defence of Bergen-op-Zoom, which was besieged by the French, and he actually crossed the sea with that view; but he had scarcely reached the Dutch camp, before the French, owing either to negligence or treachery in the garrison, unexpectedly became masters of the place.

In the year 1748, Anson's "Voyage round the World" was published, bearing the name of Walter in the title-page, though it was soon known to have been Mr. Robins's production. No work of the kind ever met with a more favourable reception: four large editions were sold within a year, and it has been since reprinted very frequently in all sizes. It was translated in almost all the European languages. He was next employed to draw up an apology for the unfortunate defeat of the king's troops by the rebels, at Preston-Pans in Scotland, which was prefixed to "The Report of the Proceedings and Opinion of the Board of General Officers, on their Examination into the Conduct of Lieutenant-General Sir John Cope," &c.

After this, Mr. Robins had opportunities, through the favour of lord Anson, of making further experiments in gunnery; an account of which, with other pieces, were published after his death. Through the interest of the same nobleman, he contributed to the improvement of the Royal Observatory of Greenwich, by procuring for it many valuable instruments. In the year 1749 he was made engineer-general to the East India Company; and with a complete set of astronomical instruments, for making observations and experiments, he arrived in India in the summer of 1750. He set about the business which he had undertaken immediately, with the utmost diligence, and soon formed plans for fort St. David and Madras; but he did not live to carry them into execution. The change of climate was more than he could endure, and he died at the early age of 44, in July 1751.

Mr. Robins was one of the most accurate and elegant mathematical writers of this country, and he made more real improvements in artillery, and on subjects relating to the resistance of the air to projectiles, than all the preceding authors on the subject. His "New Principles of Gunnery" were translated into various languages, and commented upon by several eminent mathematicians. Euler translated it into the German, and accompanied the version with a large and critical commentary. This again was published in England, with an English translation of the German commentary and notes, by Mr. Hugh Brown, in 1777. All Mr. Robins's mathematical and philosophical pieces were collected, and published in 2 vols. 8vo. 1761, by Dr. Wilson, with an account of the author, from which the foregoing article is chiefly extracted.

ROBINSON, ROBERT, born in October 1735, at Swaffham, in the county of Norfolk, was son of Mr. Michael Robinson, a native of North Britain, and Mary, the daughter of Mr. Robert Wilkin of Mildenhall, Suffolk, a man of great respectability in private life, and in possession of a moderate independence. Robert was the youngest of their three children: his elder brother was apprenticed to a painter, and his sister to a mantua-maker; he was sent to a Latin school at the age of six years, where he made a considerable proficiency, and discovered an uncommon capacity for learning. His father, in the course of his profession, was removed from Swaffham to Scarning, in the same county, where finding his situation very unpleasant, he left the place, his family returning home, and he shortly after died at Winchester. At Scarning young Robinson was sent to an endowed grammar-school, then under the care of the Rev. Joseph Brett. Several persons of eminence received the early parts of their education at the same school, among whom was the late lord Thurlow. At this school he gained a considerable knowledge of the French, as well as of the classical languages. At the age of 14 he was put apprentice to a hair-dresser, in Crutched-Friars, London. For this occupation his mind was very ill adapted, and he stole from the hours devoted to sleep no small portion of time for the improvement of his mind. During his apprenticeship he appears to have imbibed serious impressions of religion, which he encouraged, by attending the most celebrated preachers of the day among the Independents, the Baptists, and the clergy falsely named evangelical; for they dwell, in their pulpit discourses, upon all sorts of subjects, excepting only those contained in the four gospels. Dr. Guise and Gill among the dissenters, Romaine in the church, and Whitfield, the leader of the Calvinistical Methodists, were his chief favourites. At this period Robert Robinson had a considerable portion of enthusiasm in his constitution, which is not an undesirable quality in young people

people left much to themselves, and liable to a thousand temptations in corrupt and licentious cities and large towns. It is often the best preservative of their morals, and will frequently grow into rational and energetic modes of thinking and acting.

About the age of 20, Robert Robinson had his indentures given him up, at his own request, feeling a great desire to become a preacher. He had, previously to this, been in the habit of preaching for the hour together to himself, thinking that he should thereby be better prepared to address an audience assembled to hear his discourses. His first sermon was delivered to a very small congregation at Mildenhall, in Suffolk; and his reception was such as to justify the hope that he had taken that direction to which his talents naturally tended. He was soon after invited to preach at the Tabernacle in Norwich, and at several places in Norfolk and Cambridgeshire. He continued to preach among the Methodists two years, during which period he appears to have turned his attention more particularly to the controversy between the members of the established church and the dissenters, and to have determined, upon the fullest conviction, to take his lot with the latter. He had, however, according to Dr. Rees, who preached his funeral sermon, a temptation to connect himself with the former, too powerful for any but a man of Christian integrity to resist. "A rich relation," says the doctor, "who had promised to provide liberally for him, and who had bequeathed him a considerable sum of money in his will, threatened to deprive him of every advantage which he had been encouraged to expect, unless he quitted his connection with the dissenters. But the rights of conscience, and the approbation of God, were superior in his regard to every worldly consideration: he preferred his integrity, steadily maintained his principles, and persevered in his connection with the dissenters; but forfeited the favour of his relation, and every advantage which, living or dying, he had in his power to bestow."

He now attempted to incorporate the Methodists, among whom he ministered, into a regular church; but proving unsuccessful, he determined to separate from them. Having done so, he formed a small *Independent* congregation at Norwich, and during his connection with them, he administered infant baptism; but on leaving this congregation, he renounced infant baptism, and administered this ordinance only to adults, and by immersion.

In the spring of 1759 he was invited to preach to a small congregation of Antepedobaptists at Cambridge. About the same time he married Miss Ellen Payne; and in 1761 he accepted the pastoral office in this church. When Mr. Robinson first settled with this society, it consisted only of 34 members, most of whom were very poor, so that he could look only for a salary of a few pounds at most; but it increased rapidly under him, and in a few years he had the satisfaction of seeing a new and more commodious place of worship, erected at the sole expence of the congregation; and in 1774, the number of families connected with it was not less than 200, many of whom ranked among the most respectable in the town and neighbourhood. Mr. Robinson preached twice or thrice on each Sunday, and usually once on some other day in the week, at Cambridge. On some of the other mornings and evenings in the week, excepting in times of hay and corn-harvest, he expounded the scriptures, or delivered religious and moral lectures, in the village where he lived, or in the neighbouring villages. To young persons he rendered essential service, by delivering lectures to them at his own house, or by private conversation. These various employments of his time he rendered consistent with his other numerous engagements, and close

application to study, by the excellent habit which he had acquired, when young, of rising early in the morning, *viz.* at four or five o'clock; a practice that ought to be recommended to every student. "I wish," says the late Gilbert Wakefield, speaking on the same subject, "my advice and imperfect experience of its benefits could persuade every youth to engrave it, in impressions not to be effaced, on the tablet of his heart, and exemplify it in his daily practice."

" ————— Ni

Pofces ante diem librum cum lumine; si non  
Intendes animum studiis et rebus honestis,  
Invidiâ vel amore vigil torquebere."

"Rise, light thy candle, see thy task begun,  
E'er redd'ning streaks proclaim the distant sun;  
Or lust's fierce whirlwind will thy calm molest,  
Or envy cloud the sunshine of thy breast."

Soon after the opening of the new meeting-house, the abilities of Mr. Robinson as a preacher began to attract the notice of the academics, many of whom, from serious motives, became regular attendants; while others came to meeting only to indulge their curiosity, or perhaps to ridicule the minister. Of the latter description were several under-graduates, who frequently disturbed the devotion of the congregation by an indecency of behaviour. Complaints of their conduct had been repeatedly made to the magistrates of the university, and the heads of the colleges, but without procuring redress. At length the rudeness of these young men required measures to be taken, which should no longer be treated with contempt. A legal process was begun, which induced two of the worst offenders to agree to ask pardon in the public papers. The persons aggrieved, however, remitted this punishment in the case of one of the delinquents, on account of his otherwise excellent character. The evil was, by this measure, well nigh cured, and Mr. Robinson had little or no reason to complain afterwards of interruption from that quarter. From this period, many of the most respectable members of the university solicited his acquaintance, and entertained a due respect for his worth, however they differed from him in opinion; and through their aid and influence, he obtained freedom and access to the valuable libraries at Cambridge, and was permitted, in many cases, the more important privilege of having books from them at his own house.

In the year 1773, Mr. Robinson's family having become so numerous that his salary as a minister was found inadequate to his support, he found it necessary to have recourse to other means for making a provision for them. He accordingly removed to Chesterton, near Cambridge, and commenced farmer, to which, in time, he added the business of a dealer in corn and coals. His farming and mercantile engagements, however, did not diminish his ardour for literary pursuits, as is evident from his various publications. The first work which contributed to make him known as an author, was published in 1774, under the title of "Arcana," or the Principles of the late Petitioners to Parliament for relief in Matters of Subscription, in eight letters to a friend. The reception which this piece met with was extremely encouraging: it procured the author many valuable friends among the dissenters. His next publication was an "Appendix" to "The Legal Degrees of Marriage, stated and considered by John Allyn, Barrister at Law," 2d edition, 1775. It consists of a discussion of the question, "Is it lawful and right for a man to marry, the sister of his deceased wife?" in which he maintained, in a

very

very forcible manner, the affirmative side of the question. In the same year he published an entire volume of "Sermons, from the original French of the late Rev. James Saurin, Pastor of the French Church at the Hague," which was followed, at different periods, by four others. Introductory to these volumes are prefatory dissertations, containing interesting memoirs of the Reformation in France, and the life of Saurin, together with reflections on Deism, Christian liberty, &c. The fame which Mr. Robinson acquired by this publication, induced certain divines, and among them dignitaries of the established church, to offer him liberal terms for original sermons for their own use.

In the year 1776, the controversy respecting the divinity of Christ, which had been carried on principally by members of the church of England, some of whom had resigned their livings, much engaged the public attention. Mr. Robinson appeared on the popular side of the question, and published "A Plea for the Divinity of our Lord Jesus Christ, &c." This piece is written with much ingenuity, and it procured the author a number of handsome compliments, not only from dissenting ministers, but also from several dignitaries of the established church. Among the latter were Dr. Hinchliffe, bishop of Peterborough, Dr. Hallifax, afterwards bishop of Gloucester, Dr. Beadon, afterwards bishop of Bath and Wells, and Dr. Tucker, dean of Gloucester. Some years after, Mr. Lindsey published, without his name, "An Examination of Mr. Robinson's Plea for the Divinity of Christ;" in a second edition, in 1789, Mr. Lindsey prefixed his name. Mr. Robinson was frequently called upon to reply to Mr. Lindsey, but he declined. To his friends he said, "The anonymous examiner has not touched my arguments, and his spirit is bitter and contemptuous. His faith stands on criticisms; and my argument is, that if the doctrine requires critical proof, it is not popular, and therefore not divine." In 1777, Mr. Robinson published a small tract, entitled "The History and Mystery of Good Friday," that has passed through numerous large editions, and in which the evil and folly of church holidays is with equal humour, learning, and argument, unanswerably demonstrated. In 1778, Mr. Robinson published "A Plan of Lectures on the Principles of Non-conformity, for the Instruction of Catechumens." This piece contains an outline of the whole controversy of the dissenters with the church of England, and of their history, from the period of the Reformation, to the year 1778. In the house of lords it was mentioned with due respect by the earl of Shelburne; and it was ably defended in the house of commons by Mr. Fox, in opposition to an illiberal attack upon the principles of dissent, from the eloquent Mr. Burke, whose calumnies were confined to no people nor set of principles. Towards the close of the same year, Mr. Robinson published "An Essay on the Composition of a Sermon, translated from the original French of the Rev. John Claude, with Notes," in 2 vols. 8vo. The preface to the first volume of the "Essay" consists of memoirs of the life of the author.

In 1780, Mr. Robinson paid a visit to the university of Oxford, and afterwards accompanied some friends in a tour into Scotland, where he was much gratified by civilities shewn him by some of the literati of Edinburgh; and he might have received the diploma of doctor of divinity, had he not thought proper to decline that compliment. Soon after his return to Cambridge, he published a little tract well calculated to produce a Catholic spirit among his brethren of the Baptist denomination, entitled "The General Doctrine of Toleration, applied to the particular Case of Free Communion." It was about this period he

preached and published a sermon, entitled "Slavery inconsistent with the Spirit of Christianity," and he was the author of the admirable petition of the gentry, clergy, freeholders, and other inhabitants in the county of Cambridge, which was presented to the house of commons. In the year 1781, Mr. Robinson, at the desire of his brethren, began to collect materials for the History of the English Baptists. In his researches he was led to enter on a larger field than what had been originally proposed to him, and instead of confining himself to the history of English Baptists, he was induced to trace the history of baptism from the earliest use of that rite, as well as that of Baptists in all ages.

In the year 1782, Mr. Robinson published "A Political Catechism," intended to convey, in a familiar manner, just ideas of good civil government, and the British constitution. This tract was written at the time that the North administration was discarded from the councils of their sovereign for that of the marquis of Rockingham. To support the system professed by the latter—to disseminate safe political principles—to place public happiness on its true basis, were the motives which induced Mr. Robinson to endeavour to attract the attention of youth to this subject. This work, as well as the preface to the "Plan of Lectures," and his sermon, entitled "Christian Submission to Civil Government," afford ample evidence of the soundness of his principles as a friend to civil government in general, and to that form of civil government, the British constitution, in particular. It was in 1786 that Mr. Robinson published "Sixteen Discourses on several Texts of Scripture, addressed to Christian Assemblies, in Villages near Cambridge; to which are added Six Morning Exercises." These discourses were delivered extempore to plain and illiterate audiences, in a simple but animated style; and they were afterwards written out, from memory, by the author, as nearly as he could recollect them. They are chiefly on practical subjects; but such of them as touch on doctrinal subjects display much candour and liberality. This spirit of liberality excited serious apprehensions concerning the purity of his faith among many of his orthodox friends, who expostulated with him, both in person and by letter. Soon after this he afforded real ground for entertaining apprehensions that his faith in the gloomy doctrines of Calvinism was not so strong as in the opinion of his brethren it ought to have been. Many of them attacked him in their pulpits, endeavouring to diminish his well-earned popularity, by stigmatizing him with the names of Arian and Socinian; but others, though themselves zealously attached to those doctrines, which he seemed inclined to abandon, continued his faithful and invariable friends. With his congregation at Cambridge he still continued his ministerial labours; he had been the minister of their choice, and remained high in their esteem.

During the latter years of his life, the large field of enquiry upon which Mr. Robinson had entered, led him to such a course of intense application, as undermined the strength of his constitution, before he had given the finishing hand to his labours, and brought on a gradual decay, attended with a great depression of spirits. In these circumstances, it was hoped by his family that a journey to Birmingham, and an interview with Dr. Priestley, which he had long wished for, might prove beneficial to him. Having arrived at that town, he ventured to preach twice on the same Sunday for the benefit of the charity schools. His friends perceived that he was ill, but none of them suspected his end was so near; he spent the evening of the following Tuesday in the cheerful society of his friends,

and retired to rest as usual; but on the next morning he was found dead in his bed, where he appears to have expired exactly as he hoped it might be permitted him to leave the world, suddenly—and alone, without feeling the agonies of death, or occasioning alarm or distress to affectionate relatives and friends. He died June 8th, 1790, in the 55th year of his age.

Mr. Robinson was a wonderful example of a man who rose to considerable eminence by his own exertions. To his great talents and extensive learning his various writings bear the fullest testimony. He possessed an ardent love of truth, was laborious in the search after it, and at all times was a strenuous advocate for such principles as he had adopted upon deliberate conviction, while he ever exercised candour and liberality toward those whose opinions differed from his own. Of civil and religious liberty he was the enlightened, steady, and zealous friend. In his domestic relations he was attentive and affectionate; and to the poor a friend, comforter, and, as far as his limited means permitted, a generous benefactor. As a preacher, “there was always a variety, and often an originality, both in what he said, and in his mode of saying it. It was his constant aim to lead the attention of his hearers to the weightier matters of the law; to inform the judgment before he attempted to interest the passions; and, after inculcating just notions of truth and duty, to enforce a corresponding practice. There have been few preachers who have done so much to rescue the human mind from bondage; to correct prevailing errors; to promote a liberal spirit of inquiry; to recommend mutual forbearance and candour among Christians of different opinions; to weaken their attachment to creeds and forms of human device and imposition, and to direct their chief attention to the principles and duties of piety, virtue, and universal charity. He had a manner of supplanting rooted prejudices without occasioning alarm; of sapping instead of storming the fortifications of error; of gaining assent to general principles, inconsistent with the opinions which he wished to expose; and of leading men to think, judge, and determine for themselves, and to pursue these principles to their consequences, in which he wonderfully excelled, and which produced, in many instances, the best effects.” See Dr. Rees’s Sermon before referred to.

It has already been observed, that Mr. Robinson died before he had completed the great work to which his attention had been chiefly confined for several years. One part of his comprehensive plan, however, was finished, and the whole, excepting a few sheets, printed off, and corrected by himself while passing through the press. This was published in the year 1790, under the title of “The History of Baptism,” which is one of the most acute and ingenious defences of the distinguishing tenets of the Baptists which has ever yet appeared, deduced not only from the records of history, but from the relics of Christian antiquity, being illustrated with engravings from ancient paintings and buildings, and from Danish and Saxon remains in our British churches. This part of the plan was to have been followed by a history of the Baptists, which was left in an incomplete state, but which was published in 1792, under the title of “Ecclesiastical Researches.” This work was carried through the press under the superintendance of Mr. Friend, who had long enjoyed the friendship of Mr. Robinson. Besides much information which these researches contain, that is not to be found in any other English work on the subject, and the interesting views of the progress of civil and religious liberty, together with well-drawn characters of its principal advocates,

the reader will meet with a variety of important and excellent matter on other topics: the author has introduced into his narrative ingenious remarks, useful to elucidate the leading object of his inquiries, on the geography, government, laws, antiquities, commerce, productions, and customs and manners of the inhabitants of the several countries treated of. Since the death of the author, Mr. Benjamin Flower has collected all Mr. Robinson’s works, with the exception of his “History of Baptism,” “Ecclesiastical Researches,” “Claude’s Essay on the Composition of a Sermon,” and his “Village Sermons,” and published them in four volumes, 8vo., to which we refer our readers, who will find, by looking them over, that we have in our enumeration of Mr. Robinson’s works omitted some of minor importance. And in the year 1812, the same person published certain posthumous pieces of our author in one volume octavo: these, on the whole, cannot be said to add to the reputation of Mr. Robinson; they consist of seven sermons, and three dissertations, “On the Nature and Operations of the Human Mind, as relating more particularly to Theological Inquiries;” “Literary Precautions necessary to the Study of Theology;” “On Predestination; or, Moderate Calvinism considered as the safe Path between Two Extremes.” To these tracts are added “An Historical Account of Protestant Dissenting Churches in Cambridgeshire,” and divers of Mr. Robinson’s letters. See Dr. Rees’s Sermon on the Death of Mr. Robinson; Dyer’s Life of Robinson, 1796; and Flower’s Memoirs, prefixed to the first vol. of the Miscellaneous Works, 1807.

ROBINSON, RICHARD, archbishop of Armagh, and baron Rokeby, was born in 1709. He was educated at Westminster school, from whence he was elected to Christ-church, Oxford, after which he became chaplain to archbishop Blackburne, of York, who gave him a prebend in his cathedral. He went with the duke of Dorset to Ireland, and was preferred to the see of Killala, from whence, in 1759, he was translated to Leighlin and Ferns, and in 1761 to Kildare. In 1765 he was advanced to the primacy of Ireland, and in 1777 he was created a peer. He built a palace in his diocese of Armagh, with an observatory. (See the article OBSERVATORY.) He also founded a school, and built four new churches. He died in 1794. Europ. Mag.

ROBINSON, JOHN, organist of St. Laurence Jewry, of St. Magnus church, and of Westminster abbey. He was regarded as one of the best performers on keyed instruments of his time. As an organ-player he was attended by great crowds wherever he performed. He was educated in the chapel-royal, under Dr. Blow. His wife was the daughter of Dr. William Turner, and a public singer. She performed in Scarlatti’s opera of Narcissus, brought on the stage by Roscigrave, in 1720; and to distinguish her from Mrs. Anassafia Robinson, who sung in the same opera, she was called Mrs. Turner Robinson. This celebrated organist died at an advanced age in 1762, and was succeeded, in Westminster abbey, by Dr. Benjamin Cook.

ROBINSON, *Miss*, daughter of the celebrated organist of Westminster abbey, who sung at concerts, and, one season, in Handel’s oratorios. She was a coarse singer, with an unpleasant toned voice; but that did not prevent her from becoming a great player on the harpsichord; particularly on a harpsichord made by Rucker, with pedals, of which she had acquired, by labour and perseverance, a facility of execution equal to German organists. The result, however, was not equal to the great difficulty of using them. The pedals of an organ often produce fine effects in sustaining notes with the feet, while both hands are at liberty to ramble

about in the treble at their pleasure. But on a harpsichord with pedals to short-lived sounds, the clatter of striking them so often is abominable; it is not music, but noise.

ROBINSON, *Mrs.* ANASTASIA, a most amiable and accomplished person, who performed as a singer in our first Italian operas, from the year 1714 to 1724. This performer, descended from a good family in Leicestershire, was the daughter of a portrait painter, who, having visited Italy for improvement in his art, had made himself master of the Italian language, and acquired a good taste in music. And finding that his daughter Anastasia, during her childhood, had an ear for music, and a promising voice, he had her taught by Dr. Crofts, at first as an accomplishment; but afterwards being afflicted with a disorder in his eyes, which terminated in a total loss of sight; and this misfortune depriving him of the means of supporting himself and family by his pencil, he was under the necessity of availing himself of his daughter's disposition for music, to turn it to account as a profession. She not only prosecuted her musical studies with great diligence, but by the assistance of her father had acquired such a knowledge in the Italian tongue as enabled her to converse in that language, and to read the best poets in it with facility. And that her taste in singing might approach nearer to that of the natives of Italy, she had vocal instructions from Sandoni, at that time an eminent Italian singing master resident in London, and likewise from the opera singer called the Baroness.

Her first public exhibition was at the concerts in York-buildings, and at other places, where she usually accompanied herself on the harpsichord. Her general education had been pursued with the utmost care and attention to the improvement of her mind, as well as to ornamental and external accomplishments; and these advantages, seconded by her own disposition and amiable qualities, rendered her conduct strictly prudent and irreproachable. And what still entitled her to general favour, was a behaviour full of timidity and respect to her superiors, and an undisssembled gentleness and affability to others, which, with a native cheerfulness that diffused itself to all around her, gained her at all times such a reception from the public, as seemed to ensure her success in whatever she should undertake. Encouraged by the partiality of the public towards his daughter, and particularly by the countenance and patronage of some persons of high rank of her own sex, Mr. Robinson took a house in Golden-square, where he established weekly concerts and assemblies in the manner of *conversazioni*, which were frequented by all such as had any pretensions to politeness and good taste.

Thus qualified and encouraged, she was prevailed upon to accept of an engagement at the Opera, where she made her first appearance in Cresco, and her second in the character of Imina, the principal female part in Arminio. From this period till the year 1724, she continued to perform a principal part at the Opera with increasing favour and applause. Her salary is said to have been 1000*l.*, and her emoluments, by benefits and presents, were estimated at nearly as much more. When she quitted the stage it was supposed to have been in consequence of her marriage with the gallant earl of Peterborough, the friend of Pope and Swift, who distinguished himself so heroically in Spain during the reign of queen Anne. Though the marriage was not publicly declared till the earl's death in 1735, yet it was then spoken of as an event which had long taken place. And such was the purity of her conduct and character, that she was instantly visited at Fulham as the lady of the mansion, by persons of the highest rank. Here, and at Mount Bevis, the earl's seat near Southampton, she resided in an

exalted station till the year of her decease, 1750, surviving her lord fifteen years; who, at the time of the connexion, must have been considerably beyond his prime, as he was arrived at his seventy-fifth year when he died.

The following anecdotes of Mrs. Anastasia Robinson having been communicated to us in 1787, by the late venerable Mrs. Delany, her contemporary and intimate acquaintance, they will doubtless be read with confidence and pleasure, not only by such as had the happiness of knowing her personally, but by all those to whom rumour has conveyed a faithful account of her longevity, virtues, and accomplishments; for this excellent person having been allowed by Providence to extend her existence to the great age of eighty-eight, in the constant enjoyment of all the felicity which the friendship and admiration of rank, virtue, and talents could bestow; it seems as if, without hyperbole, she may be said to have been "beloved by God and man."

"Mrs. Anastasia Robinson was of a middling stature, not handsome, but of a pleasing, modest countenance, with large blue eyes. Her deportment was easy, unaffected, and graceful. Her manner and address very engaging; and her behaviour, on all occasions, that of a gentlewoman, with perfect propriety. She was not only liked by all her acquaintance, but loved and caressed by persons of the highest rank, with whom she appeared always equal, without assuming. Her father's house, in Golden-square, was frequented by all the men of genius and refined taste of the times; among the number of persons of distinction who frequented Mr. Robinson's house, and seemed to distinguish his daughter in a particular manner, were the earl of Peterborough and general H—; the latter had shewn a long attachment to her, and his attentions were so remarkable, that they seemed more than the effects of common politeness; and as he was a very agreeable man, and in good circumstances, he was favourably received, not doubting but that his intentions were honourable. A declaration of a very contrary nature was treated with the contempt it deserved, though Mrs. A. Robinson was very much prepossessed in his favour.

"Soon after this, lord P. endeavoured to convince her of his partial regard for her; but, agreeable and artful as he was, she remained very much upon her guard, which rather increased than diminished his admiration and passion for her. Yet still his pride struggled with his inclination; for all this time she was engaged to sing in public, a circumstance very grievous to her, but urged by the best of motives, she submitted to it, in order to assist her parents, whose fortune was much reduced by Mr. Robinson's loss of sight, which deprived him of the benefit of his profession as a painter.

"At length lord P. made his declaration to her on honourable terms; he found it would be vain to make proposals on any other; and as he omitted no circumstance that could engage her esteem and gratitude, she accepted them, as she was sincerely attached to him. He earnestly requested her keeping it a secret till it was a more convenient time for him to make it known, to which she readily consented, having a perfect confidence in his honour. Among the persons of distinction that professed a friendship for Mrs. A. Robinson, were the earl and countess of Oxford, daughter-in-law to the lord-treasurer Oxford, who not only bore every public testimony of their affection and esteem for Mrs. A. Robinson, but lady Oxford attended her when she was privately married to the earl of P., and lady P. ever acknowledged her obligations with the warmest gratitude; and after lady Oxford's death, she was particularly distinguished by the duchess of Portland, lady Oxford's daughter,

and was always mentioned by her with the greatest kindness for the many friendly offices she used to do her in her childhood when in lady Oxford's family, which made a lasting impression upon the dukes of Portland's noble and generous heart.

"Mrs. A. Robison had one sister, a very pretty accomplished woman, who married Dr. Arbuthnot's brother. After the death of Mr. Robison, lord P. took a house near Fulham, in the neighbourhood of his own villa at Parson's-Green, where he settled Mrs. Robison and her mother. They never lived under the same roof, till the earl, being seized with a violent fit of illness, solicited her to attend him at Mount Bevis, near Southampton, which she refused with firmness, but upon condition that, though still denied to take his name, she might be permitted to wear her wedding ring; to which, finding her inexorable, he at length consented.

"His haughty spirit was still reluctant to the making a declaration, that would have done justice to so worthy a character as the person to whom he was now united; and, indeed, his uncontrollable temper, and high opinion of his own actions, made him a very awful husband, ill suited to lady P.—'s good sense, amiable temper, and delicate sentiments. She was a Roman Catholic, but never gave offence to those of a contrary opinion, though very strict in what she thought her duty. Her excellent principles and fortitude of mind supported her through many severe trials in her conjugal state. But at last he prevailed on himself to do her justice, intimated, it is supposed, by his bad state of health, which obliged him to seek another climate, and she absolutely refused to go with him unless he declared his marriage; her attendance upon him in his illness nearly cost her her life.

"He appointed a day for all his nearest relations to meet him at the apartment over the gate-way of St. James's palace, belonging to Mr. Pointz, who was married to lord Peterborough's niece, and at that time preceptor to prince William, afterwards duke of Cumberland. Lord P. also appointed lady P. to be there at the same time; when they were all assembled he began a most eloquent oration, enumerating all the virtues and perfections of Mrs. A. Robison, and the rectitude of her conduct during his long acquaintance with her, for which he acknowledged his great obligations and sincere attachment, declaring he was determined to do her that justice which he ought to have done long ago, which was presenting her to all his family as his wife. He spoke this harangue with so much energy, and in parts so pathetically, that lady P. not being apprised of his intentions, was so affected that she fainted away in the midst of the company.

"After lord P.—'s death she lived a very retired life, chiefly at Mount Bevis, and was seldom prevailed on to leave that habitation, but by the dukes of Portland, who was always happy to have her company at Bulltrode, when she could obtain it, and often visited her at her own house.

"Among lord P.—'s papers he found his memoirs, written by himself, in which he declared he had been guilty of such actions as would have reflected very much upon his character. For which reason she burnt them; this, however, contributed to complete the excellency of her principles, though it did not fail giving offence to the curious enquirers after anecdotes of so remarkable a character as that of the earl of Peterborough."

ROBINSON'S *Island*, in *Geography*, a small island in the Florida streams. N. lat. 24° 43'. W. long. 81° 35'.

ROBINSON *Crisp's Coat*, in *Botany*. See CACTUS.

ROBINSONIA, was so named by Scopoli, in his *Intro-*

*ducto ad historiam naturalem*, in honour of one, or all, of the four Robisons, mentioned in Haller's *Bibliotheca Botanica*. The worthy author informed us, by word of mouth, that Haller's index was his usual resource for names to his new genera; any person mentioned there being, in his opinion, sufficiently worthy of this kind of commemoration. It is pity that Robison Cruso was not in the list, or he might have shared a botanical crown with Cook and Bouganville. If we must seriously appropriate the above honour, it would be in favour of Dr. Tancred Robison, a particular friend, and botanical associate, of Ray.—Schreb. 337. Willd. Sp. Pl. v. 2. 999. Mart. Mill. Dict. v. 4. (Touroulia; Aubl. Guian. v. 1. 492. Juss. 434. Lamarck Illustr. t. 424.)—Class and order, *Icosandria Monogynia*. Nat. Ord. uncertain, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, turbinate, with five acute teeth. *Cor.* Petals five, roundish, concave, spreading, inserted into the calyx. *Stam.* Filaments numerous, capillary, swelling upwards, inserted into the calyx beneath the petals; anthers of two oblong cells, divaricated at the base. *Pist.* Germen superior; style none; stigma oblong, striated. *Peric.* Berry globose, somewhat depressed, marked with numerous, contiguous, longitudinal furrows, fleshy, of seven cells, with membranous partitions. *Seeds* solitary, oblong, compressed, externally convex, hairy.

Ess. Ch. Calyx five-toothed. Petals five. Berry superior, striated, of seven cells. Seeds solitary, hairy.

1. *R. melianthifolia*. Willd. n. 1. (Touroulia guianensis; Aubl. Guian. v. 1. 492. t. 194.)—Found by Aublet in the forests of Guiana, where the inhabitants know it by the name of Touroulia. The flowers appear in November, and the fruit is ripened in May. A large and lofty tree, with a wrinkled bark, and red wood; the branches spreading, quadrangular. *Leaves* opposite, pinnate, of about four pair, with an odd one, of elliptic-oblong, pointed, smooth; serrated leaflets, whose lateral veins are numerous and parallel, and their serratures each tipped with a bristle. *Stipulas* acute. *Clusters* terminal, compound, with opposite branches. *Flowers* tufted, nearly sessile, yellow, small. *Berry* an inch in diameter, reddish, of a pleasant acid flavour. The calyx being certainly inferior, as Jussieu determined by examination, its teeth can hardly crown the fruit, though, by Aublet's description, its base seems confluent therewith.

ROBION, or ROUBION, in *Geography*, a river of France, which runs into the Rhone, a little below Montelimart.

ROBISON, JOHN, in *Biography*, an eminent Scotch mathematician and natural philosopher, was born at Boglehall, in the county of Stirling, in the year 1739. He was sent to Glasgow to receive his education, and was soon distinguished for the rapid progress which he made in classical learning. He went, while very young, to the university, where he enjoyed the benefit of the instructions of professors Simson, Leechman, Moore, Smith, and others. He was led to attach himself particularly to the mathematics, by perceiving how successfully that science was applied to several branches of natural philosophy. Dr. Robert Simson was his tutor in mathematics, and in his class Mr. Robison was soon distinguished beyond any of his fellow students. Among other branches, Mr. Robison made himself well acquainted with the modes of algebra; but from professor Simson he derived a peculiar disposition to the study of geometry, assigning, for a reason, what others have often done, who are tolerably conversant with both subjects, that in the longest demonstration, the geometrician has clear and accurate ideas, which the most expert algebraist can very seldom have. Mr.

Robison had been designed, by his father, for the clerical profession, but it appears he became dissatisfied with it on account of some of the tenets in the established creed. Accordingly, in 1757, he was candidate for the office of assistant to Dr. Dick, in the professorship of natural philosophy, but, being then only 19 years of age, he was deemed too young for the duties attached to that situation, and in the following year he went to sea as mathematical tutor to Mr. Knowles, the eldest son of admiral Knowles. He embarked, with his pupil, on board the *Neptune*, of 90 guns, bound to Quebec; and, in the course of the voyage, Mr. Knowles being appointed lieutenant on board the *Royal William*, Mr. Robison accompanied him into that ship, and, at his own request, was rated as midshipman. In this ship he spent three years, which he thought the happiest part of his life, and during this period he acquired that knowledge of the art of seamanship which qualified him to draw up the article on that subject in the *Encyclopædia Britannica*, which was understood to be his. While on board this vessel, in the river St. Lawrence, he noticed a connection between the aurora borealis and the direction of the magnetic needle, which he pointed out to the gentlemen on the quarter-deck. During the siege of Quebec, Mr. Robison was sent, with a party of seamen and petty officers, to reinforce the crew of the *Sterling-Castle*, which was lying before the city, and was thus enabled to see much service both on board and on shore. He was likewise not unfrequently employed in taking surveys of different parts of the river. Upon the surrender of Quebec he returned to the *Royal William*, and spent the whole of the following year in the Bay of Biscay, and on the coasts of Spain and Portugal. In the year 1762, upon the expectation of future preferment from lord Anson, then first commissioner of the admiralty, he went to Jamaica, for the purpose of trying Harrison's time-keeper, and on his return to England he received the painful intelligence that his beloved pupil had, with the whole crew of the *Peregrine*, of which he was commander, perished, by the vessel's foundering at sea. He now felt that his prospects of advancement in the navy were very slender, and determined to return to college. Very soon after, admiral sir Charles Knowles confided to him the instruction of his younger son. At Glasgow he renewed his studies with great ardour, and in the year 1767, when Dr. Black was called to Edinburgh, the senate of the university of Glasgow, on his recommendation, appointed Mr. Robison his successor, as lecturer in chemistry. In the year 1770, sir Charles Knowles appointed him his official secretary to the court of Petersburg, whither the gallant admiral was going to assist in improving the Russian navy. They set out upon their journey over land, and passing through Liege, they were invited to dine with the prince-bishop: Mr. Robison observed, with some degree of surprise, that all the guests, and even the principal attendants, had about them the badges of free-masonry; upon some enquiries he was induced to become a member, and during his stay in that city he passed through all the degrees, till he attained the rank of Scotch master. At Petersburg he was appointed inspector-general of the corps of marine-cadets; an academy consisting of above four hundred young gentlemen and scholars, under the tuition of about forty teachers. His duty, in this office, consisted in visiting daily every class of the academy; in receiving weekly reports from each master, concerning the diligence and progress of every person in his class; and in advancing, twice in every year, the young gentlemen into higher classes, according to their respective merits. Of these he was constituted the sole judge, and against his decision there was no appeal. At

this period general Kutuzoff was military-head of the academy, and held the third place in the admiralty-college. This general approved all Mr. Robison's plans, adopted all his measures, and supported his authority. While in this situation, Mr. Robison presented to the admiralty-college a plan for rendering the magnificent docks at Cronstadt of some use by means of a steam-engine, which was adopted and executed with success after he had left Russia. Being attached, by his office, to that island, he found it, particularly in winter, to be a dismal solitude, where he was nearly cut off from all society. On this account, having held the appointment about four years, he determined to resign it, and to accept of an invitation from the magistrates and town-council of Edinburgh, to be professor of natural philosophy in their university. This situation he filled with great honour to himself, as well as benefit to the students of the university, till his death, which happened in 1805.

Although Dr. Robison laboured under a very distressing and painful disorder during the last eighteen years of his life, still in general his mind was active. He is well known to be author, not only of the article *Seamanship*, already mentioned, but of all the most important mathematical and philosophical articles in the third edition of the *Encyclopædia Britannica*, and the supplement to that work. They were probably the substance of his lectures delivered at college, and several of them were afterwards thrown into a different form, and published under the title of "*Elements of Mechanical Philosophy*." In 1797 this gentleman published a work, entitled "*Proofs of a Conspiracy against all the Religions and Governments of Europe, carried on in the Secret Meetings of Free-Masons, Illuminati, and Reading Societies*," a work full of declamation and absurdity, but which, owing to the furor of the times, made a great impression, and rapidly passed through several editions, but which, when reason returned to the great mass of the people, fell into deserved contempt. In 1803 Mr. Robison performed a very acceptable service to the public, by giving them an edition of Dr. Black's lectures on the "*Elements of Chemistry*," in two vols. 4to.

ROBLEDA, in *Geography*, a town of Spain, in the province of Leon; 22 miles S. of Ciudad Rodrigo.

ROBLINTON, a township of Washington county, in Pennsylvania, containing 770 inhabitants.

ROBO, a town of Arabia, in the province of Yemen; 12 miles E.N.E. of Zebid.

ROBOAN. See RUBIN.

ROBORANTIA, in *Medicine*, *strengtheners*; or such medicines as strengthen the parts, and give new vigour to the constitution.

ROBORTELLO, FRANCESCO, in *Biography*, an Italian man of letters, born at Udine in 1516, was the son of a notary and noble of that city. He was educated at Bologna, and about 1538 was invited to occupy the chair of eloquence at Lucca. In 1543 he removed to Pisa, where he held a similar professorship. In 1552 he was called to Padua to fill the chair of Greek and Latin eloquence, vacant by the death of Lazzaro Buonamici. He quitted Padua for Bologna in 1557; whence, in 1560, he was recalled by the senate of Venice to his chair at Padua. He died in 1567, in his 51st year. The university gave him a splendid funeral, and the German nation erected a handsome monument to his memory in the church of St. Antonio. At most of the places of his residence he was involved in quarrels with his colleagues, and his writings are full of attacks upon his contemporaries. He published numerous works, among which were, "*Annotations on various Authors, Greek and Latin*," 1543, republished in 1548, with several small treatises;

treatises; a corrected edition of "Aristotle's Poetics," together with a paraphrase on "Horace's Art of Poetry;" an edition of the "Tragedies of Æschylus;" of "Ælian's Tactics," with a Latin version; and of "Longinus de Sublimitate," with annotations. He also published a valuable work "De Vita et Victu Populi Romani sub Imperatoribus Cæsaribus Augustis," with ten other dissertations on subjects of Roman antiquity.

ROBUR CAROLINUM, in *Astronomy*. See ROYAL OAK.

ROBUSTI, GIACOPO, in *Biography*. See TINTORRETTO.

ROCA, or ROCCA, in *Geography*, a cluster of islands in the Caribbean sea, near the coast of South America. N. lat. 12° 20'. W. long. 66° 6'.

ROCA, *Cape*, a cape on the W. coast of Portugal, generally called by the English sailors the "Rock of Lisbon." N. lat. 38° 45'. W. long. 90° 34'.

ROCA POINT, a cape on the E. coast of England, in the county of Durham. N. lat. 55° 1'. W. long. 1° 21'.

ROCAB, a town of Arabia, in Hadramaut; 50 miles S.S.W. of Sahar.

ROCABERTI, JOHN THOMAS DE, in *Biography*, a Spanish prelate in the seventeenth century, was descended from a noble family, and born at Pefelada, on the frontiers of Catalonia, about the year 1624. He entered into the order of St. Dominic; was made provincial of Aragon in 1666; general of his order in 1670; archbishop of Valentia in 1676; inquisitor-general in Spain in 1695; and twice appointed viceroy of Valentia. By his authority as general, he selected from the mass of manuscripts belonging to his order, the most valuable unpublished labours of several of its members, which he directed to be printed, but at his own private expence. Besides some devotional tracts, he published a treatise "De Romani Pontificis Auctoritate," 1693, in three vols. folio. This work was very favourably received in Spain and in Italy; but the sale of it was prohibited in France, by a decree of the parliament of Paris. He spared no pains in procuring all the treatises which had been composed by different authors in defence of the pope's authority and infallibility, and made provision for their being printed in an uniform edition at Rome. This enormous collection is entitled "Bibliotheca Maxima Pontifica," &c., and consists of twenty-one folio volumes. The archbishop died in 1699.

ROCAIBA, in *Geography*, a town of Arabia, in the province of Hedsjas; 120 miles E.N.E. of Mecca.—Also, a town of Arabia, in the province of Nedsjed; 17 miles E. of Mecca.

ROCAMA, in *Botany*, an Arabian name, applied by Forskall, in his Fl. Ægypt-Arab. 71, to the Linnæan *Triantema pentandra*, which he there establishes as a distinct genus. See TRIANTHEMA.

ROCAMADOUR, in *Geography*, a town of France, in the department of the Lot; 22 miles N. of Cahors. N. lat. 44° 48'. E. long. 1° 42'.

ROCAMBOLE, a mild sort of garlic, by some called Spanish garlic; being much of the nature of shallot; and well known in cookery, in quality of a sauce. See ALLIUM.

ROCAPARTIDA, in *Geography*, an island in the North Pacific ocean. S. lat. 16°. W. long. 92° 14'.

ROCAS, a town of Arabia, in the province of Oman, near the sea; 30 miles W.N.W. of Oman.

ROCAVION, a town of France, in the department of the Stura; five miles S.S.W. of Coni.

ROCCA, ANGELO, in *Biography*, a learned Italian monk and titular bishop, was a native of Rocca Contrata, a town in the marche of Ancona, and born in the year 1545. When young he took the habit among the hermits of St. Augustine, and pursued his studies at Rome, Venice, Perugia, and Padua. Having distinguished himself by his proficiency in the various branches of literature, sacred and profane, he was honoured with the degree of doctor of divinity by the university of Padua, and afterwards acquired much celebrity as a preacher at Venice. His general appointment him to several confidential and honourable employments, and at last made him secretary to his order. After he had retained this post some years, pope Sixtus V. placed him in the Vatican in 1585, and confided to his superintendance those editions of the bible, the councils, and the fathers, which issued from the apostolical press during his pontificate. In the year 1595, pope Clement VIII., by way of reward for these services, made him apostolical sacristan, and titular bishop of Tagasté in Numidia. He collected a very large and excellent library, which he left by his will to the Augustinian monastery at Rome; but upon the express condition, that it should be always open for the benefit of the public. This was the first library formed in that city to which the public had freedom of access, and it was properly called, after the name of its beneficent founder, the "Angelical Library." Rocca died in 1620, at the age of 75. He published "Bibliotheca Theologica et Scripturalis;" "Notæ in Novum Testamentum;" "De Patientia;" "De Cometis;" "Observationes de Lingua Latina;" and other pieces which were collected together, and printed in two vols. folio, in the year 1719. From his manuscripts was also published, in 1745, a very curious collection, entitled "Thesaurus Pontificiarum Antiquitatum, necnon Rituum ac Cæremoniarum;" in two vols. folio.

ROCCA, in *Geography*, a town of Itria; one mile N. of Monfalcone.—Also, a town of Naples, in Lavora; 19 miles N. of Sezza.—Also, a small island in the West Indies; 24 miles W. of Orchilla.—Also, a town of the Ligurian republic; nine miles S.E. of Genoa.—Also, a town of Italy, on the east bank of lake Maggiore; 30 miles N.W. of Milan.

ROCCA, *La*, a town on the S.W. coast of the island of Canary; 15 miles S.W. of Ciudad de los Palmas.

ROCCA Albegna, a town of Etruria; 28 miles S. of Sienna.

ROCCA dell'Aspro, a town of Naples, in Principato Citra; 15 miles W.S.W. of Cangianno.

ROCCA Bruno, a town of France, in the department of the Maritime Alps, near the coast of the Mediterranean; three miles E.N.E. of Monaco.

ROCCA Contrada, a town of the duchy of Urbino; 24 miles E.S.E. of Urbino.

ROCCA del Este, a rocky islet among the Canaries; eight miles E. of Gratiofa.

ROCCA Gloriosa, a town of Naples, in Principato Citra; seven miles W. of Policastro.

ROCCA Lanzone, a town of the duchy of Parma; nine miles W.S.W. of Parma.

ROCCA del Marino, a town of Italy, in the Trevifan; 16 miles N. of Trevigio.

ROCCA Minolfa, a town of Naples, in the county of Molise; eight miles S. of Molise.

ROCCA Mensena, a town of Naples, in Lavora; three miles N. of Sezza.

ROCCA di Neto, a town of Naples, in Calabria Citra; four miles S.S.W. of Strongoli.

ROCCA del Oveste, or *West Rock*, a rocky islet among the Canaries; six miles S.W. of Alegranza.

ROCCA Romana, a town of Naples, in Lavora; six miles N. of Capua.

ROCCA Vallé Oscura, a town of Naples, in Abruzzo Citra; five miles S. of Sulmona.

ROCCA Vecchia, a town of Naples, in Lavora; 14 miles N.E. of Sezza.

ROCCA Voltraia, a town of Etruria; three miles N.E. of Volterra.

ROCCABIANCA, a town of the duchy of Parma; 15 miles N.N.W. of Parma.

ROCCABILIERE, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Nice. The place contains 1143, and the canton 3631 inhabitants, on a territory of 455 kilometres, in five communes.

ROCCALANA, a town of Italy, in the country of Friuli; 16 miles N.N.W. of Friuli.

ROCCARION, a town of France, in the department of the Stura; four miles S.W. of Coni.

ROCELLA, in *Botany*, an Italian name for that species of *Lichen*, known to our dyers under the appellation of Argol, or Orchall; for which, in dyeing red or purple, the Scottish *Lichen tartareus* is but an inadequate substitute, the colours it affords being far less permanent. See LICHEN, sect. 8. n. 115.

ROCCO RODIO, in *Biography*, an ancient Neapolitan contrapuntist and writer on music. Padre Martini (*Hor. della Mus. vol. i. p. 447.*) places Rocco Rodio at the head of the Neapolitan school, after Tinctor. But it is difficult to ascertain the exact period when Rocco Rodio flourished. We have, however, been so fortunate as to find an edition of his precepts, to which P. Martini alludes, that was printed at Naples 1609; but this date tells us nothing, as the work had certainly appeared much earlier in another form. Battista Olifante, the editor of this edition, seems not to give the rules of Rocco Rodio in his own words, but explanations of the doctrines and examples he had left. If this exposition of the rules established by Rocco Rodio was written by himself, he must have flourished late in the sixteenth century: as Adriano Willaert and Cipriano Rore are both mentioned in the text: and both these masters were living after the year 1550. The full title is the following: "Regole di Musica di Rocco Rodio, sotto brevissime risposite ad alcuni dubbj propoltozgli da un Cavaliero, intorno alle varie opinioni de Contrapontisti. Con la Dimostrazione di tutti i Canonj sopra il Canto-fermo, con li Contraponti doppij, e rivoltati, e loro regole. Aggiuntavi un' altra breve Dimostrazione de dodici Tuoni regolari, finti e trasportati. Et di nuovo da Don Batt. Olifante, Aggiuntivi un Trattato di Proportioni necessario, á detto Libro, e ristampato. In Napoli, MDVIII."

The rules and examples for composing canons of all kinds are remarkably short and clear in this tract, which is so scarce, that we have never seen it in any public library or catalogue of books; and P. Martini, who mentions the work, seems never to have been in possession of it. Our copy was purchased at the sale of the late Mr. Belway's collection of music, the admirable organist of St. Martin's church.

Rocco, in *Geography*, a town of the Ligurian republic; 11 miles S.E. of Genoa.

ROCELLA, a town of Naples, on the coast of Calabria

Citra, near which is a celebrated coral fishery; 10 miles N.E. of Giarau.

ROCH, CAPE, a cape on the E. coast of Majorca. N. lat. 39° 40'. E. long. 3° 5'.

ROCHDALE, a market-town and parish in the hundred of Salford, and county of Lancaster, England, is situated in a valley watered by the river Roch, at the distance of 46 miles S.E. from Lancaster, and 197 N.N.W. from London. In the town, besides the parish church, there are places of worship for Presbyterians, Baptists, and Methodists. Here is a free grammar-school, founded by archbishop Parker, also an English free-school, erected and endowed by Mrs. Hardman, and several Sunday-schools. The market days are Monday and Saturday; and there are fairs annually on the 14th of May, Whit-Tuesday, and the 7th of November. The petty sessions for Rochdale and Middleton division of the hundred of Salford are holden here. This town is situated in three townships, *viz.* Castleton, Spotland, and Wardleworth. The largest portion of it is within Wardleworth. The parish is of great extent, and is divided in seven districts, or townships, *viz.* Blackenworth, Butterworth, Todmorton, Wuerdale, and the three townships above-mentioned, all of which maintain their poor separately. According to the late parliamentary returns, these united districts contained 6552 houses, and 37,224 inhabitants. The vicarage here is superior in value to any other living of a similar description in the kingdom. In the reign of Henry VIII. it was rated as low as 11*l.* 4*s.* 9½*d.*, but it has since increased to nearly a hundred and fifty times that amount. It is in the gift of the archbishop of Canterbury, to whom the tithes belong, which are let for a term of years. Nine chapels of ease are attached to the church of Rochdale, *viz.* St. Mary's in the town, Littleborough, Milnrow, Todmorton, Whitworth, Friermeer, Lydgate, Saddleworth, and Dobrofs: most of which are in the patronage of the vicar. Rochdale parish is rich in the mineral products of slate, stone, and coal. It is also, and has long been, distinguished for its trade. A branch of the woollen manufacture is its staple, of which the chief articles are lays, flannels, coatings, and broad cloths; but there is likewise a considerable cotton trade carried on both in the town and its vicinity. In the township of Whitworth formerly resided Messrs. John and George Taylor, better known by the name of the Whitworth Doctors. "The fame of these rustic artists," says Dr. Aikin, "is almost equal to that of the celebrated Swiss-doctor mentioned by Mr. Coxe, and has spread not only over the more immediate neighbourhood, but to remote parts of the kingdom, and even to the metropolis itself. They were chiefly noted for setting broken and dislocated bones, and for the cure of cancerous and other tumours by caustics, properly termed by themselves *keen.*" Lord Byron, the poet, is lord of the manor of Rochdale, and takes his seat as an English peer under the title of baron Byron of Rochdale. At his court-leet, the officers and constables for the civil government of the parish are annually appointed.

The principal seats in this vicinity are Belfield, which formerly belonged to the Knights Templars; Foxholes, the residence of the Entwistle family; and Studley, long the property of the Holts, a memorable name in this district of the country. The house appears to have been erected by Robert Holt, esq. in the reign of Henry VIII. and consists of a centre and two wings. Whitaker, in his History of Whalley, describes it as containing within "much carving in wood, particularly a rich and beautiful screen between the hall and the parlour, with a number of crests, cyphers, and cognizances

cognizances belonging to the Holts, with other neighbouring families. It was abandoned for the warmer and more fertile situation of Cattleton by Robert Holt, esq. about the year 1640."

The township of Cattleton derives its name from an ancient castle which formerly reared its embattled walls within its limits, on a spot where still remains a lofty artificial mound of earth called the keep. Dr. Whitaker supposes that a castle stood here anterior to the Norman conquest, as in a record in the Harkeian collection, apparently part of an inquisition taken after the death of Thomas of Lancaster, "it is described as the site of an ancient castle long since gone to decay." A Description of the Country from thirty to forty Miles round Manchester, by J. Aikin, M. D. 4to. London 1795. Whitaker's History and Antiquities of the ancient Parish of Whalley, &c. 4to. 1806. Beauties of England and Wales, vol. ix. by John Britton, F. S. A.

ROCHDALE, a town of Pennsylvania, in Crawford county, containing 401 inhabitants.

ROCHE, a town of France, in the department of the Upper Rhine; two miles S. of Delmout.—Also, a river of America, which runs into lake Erie, N. lat.  $42^{\circ} 20'$ . W. long.  $82^{\circ} 53'$ .—Also, another which runs into the same lake, N. lat.  $41^{\circ} 48'$ . W. long.  $81^{\circ} 25'$ .

ROCHE, or *Stony River*, a river of America, which runs into the Mississippi, N. lat.  $40^{\circ} 50'$ . W. long.  $91^{\circ} 42'$ .

ROCHE, *La*, a town of France, in the department of the Leman, and chief place of a canton, in the district of Bonneville; 12 miles N.E. of Annecy. The place contains 2447, and the canton 7685 inhabitants, on a territory of 150 kilometres, in eight communes. The town is situated near the river Bonne, and is so called from a rock near it, and lies on the declivity of a hill, in a fertile country, diversified with arable lands and meadows. It is surrounded by an ancient wall and defended with towers. The principal occupations of its inhabitants are tanning of leather and making of shoes. It contains, besides a parish church, several religious houses.—Also, a town of France, in the department of Mont Blanc; 10 miles S.E. of Montier.

ROCHE, *La*, or *Roche en Ardennes*, or *en Famme*, a town of France, in the department of the Sambre and Meuse, belonging to the duchy of Luxemburg: formerly a well fortified town, with a castle commanding the town and ramparts, surrounded with the waters of the river Ourte, which passes through it. It is the capital of a comté, called "the comté of Ardennes," which comprehended 51 towns and villages. In 1703 it suffered very much from fire; 28 miles S. of Liege. N. lat.  $50^{\circ} 10'$ . E. long.  $5^{\circ} 33'$ .

ROCHE, *P'Abville*, *La*, a town of France, in the department of the Upper Vienne; 6 miles N. of St. Yriax.

ROCHE, *des Arnauds*, *La*, a town of France, in the department of the Higher Alps; 6 miles W. of Gap.

ROCHE, *Beaucourt*, *La*, a town of France, in the department of the Dordogne; 12 miles S.W. of Nontron.

ROCHE, *Bernard*, *La*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of Vannes, situated on the Vilaine; 21 miles S.E. of Vannes. The place contains 6272, and the canton 10,959 inhabitants, on a territory of 212½ kilometres, in 8 communes. N. lat.  $47^{\circ} 31'$ . W. long.  $2^{\circ} 12'$ .

ROCHE, *les Beaufre*, a town of France, in the department of the Doubs; 5 miles N.E. of Besançon.

ROCHE, *Blanche*, *La*, a town of France, in the department of the Puy de Dôme; 5 miles S. of Clermont.

ROCHE, *Bonnet*, a small island, near the W. coast of France, in the bay of Bourgneuf.

ROCHE, *Canillac*, *La*, a town of France, in the depart-

ment of the Corrèze, and chief place of a canton, in the district of Tulle; 9 miles S.E. of Tulle. The place contains 375, and the canton 6845 inhabitants, on a territory of 232½ kilometres, in 11 communes.

ROCHE, *Chalais*, *La*, a town of France, in the department of the Dordogne, on the Dronne; 15 miles S.W. of Riberaç.

ROCHE, *Darrien*, *La*, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Lannion, situated on the river Treguer; 3 miles S. of Treguer. The place contains 1102, and the canton 10,329 inhabitants, on a territory of 112½ kilometres, in 12 communes.

ROCHE, *Guyon*, *La*, a town of France, in the department of the Seine and Oise, on the Seine; 8 miles N.N.W. of Mantes.

ROCHE, *Melon*, *La*, a mountain of Piedmont, near Suza, supposed to be the highest in Italy, and to be that from the eminence of which Hannibal shewed to his army the fertile country which he thus animated them to conquer.

ROCHE, *Milley*, *La*, a town of France, in the department of the Nièvre; 12 miles S.E. of Moulins.

ROCHE, *Reigner*, *La*, a town of France, in the department of the Upper Loire; 12 miles N. of Le Puy.

ROCHE, *Servièrre*, *La*, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Montaigu; 9 miles W.S.W. of Montaigu. The place contains 425, and the canton 4542 inhabitants, on a territory of 165 kilometres, in 8 communes.

ROCHE, *sur Ton*, *La*, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Montaigu, situated on the Yon; 30 miles N.W. of Fontenay le Comte. The place contains 631, and the canton 8515 inhabitants, on a territory of 275 kilometres, in 11 communes. N. lat.  $46^{\circ} 44'$ . W. long.  $1^{\circ} 20'$ .

ROCHE, *Cape de la*, a cape on the N. coast of the island of Hispaniola. N. lat.  $19^{\circ} 42'$ . W. long.  $70^{\circ} 35'$ .

ROCHEA, in *Botany*, a genus of Decandolle's, in his *Plantes Grasses*, n. 103, dedicated to the memory of Daniel de la Roche, a physician of Geneva, whose inaugural dissertation, printed at Leyden in 1766, contains descriptions and plates of many plants of the natural order of *Eufata*, and is often cited by writers on the genera and species of that tribe. *De Theis*.

ROCHECHOUART, in *Geography*, a town of France, and principal place of a district, in the department of the Upper Vienne; 18 miles W. of Limoges. The place contains 1440, and the canton 7872 inhabitants, on a territory of 180 kilometres, in 7 communes.

ROCHEFORT, WILLIAM DE, in *Biography*, a modern French writer, was born in 1730, at Lyons. He had a small employment in the finances; but finding in himself a greater love to letters than to business, he went to Paris, and devoted himself to poetry and Greek literature. He composed three tragedies upon the Greek models, which had too much simplicity to please; and a comedy which was not more successful. In prose he published a "Refutation du Systeme de la Nature;" a "Critical History of the Opinions of the Ancients concerning Happiness;" and a "Complete Translation of the Plays of Sophocles;" the last named work gained him much credit by the elegance and fidelity of the version, and the judicious notes annexed to it. He then undertook the task of a complete translation of Homer's *Iliad* and *Odyssey*, or which the preliminary discourses and the notes obtained more applause than the version itself, which, however, he had splendidly printed at the royal press, in 1781, in 4to. He was a member of the Academy

Academy of Inscriptions and Belles Lettres, to which he contributed several learned memoirs. He died in 1788, highly esteemed for his private and social virtues. Gen. Biog.

ROCHEFORT, in *Geography*, a town of the county of Neufchatel; 5 miles S.W. of Neufchatel.—Also, a town of France, in the department of the Puy de Dome, and chief place of a canton, in the district of Clermont; 13 miles S.W. of Clermont. The place contains 110, and the canton 12,177 inhabitants, on a territory of 365 kilometres, in 14 communes.—Also, a town of France, in the department of the Jura, and chief place of a canton, in the district of Dole, seated on the Doubs; 4 miles E.N.E. of Dole. The place contains 562, and the canton 6395 inhabitants, on a territory of 107½ kilometres, in 19 communes.—Also, a town of France, in the department of the Sambre and Meuse, and chief place of a canton, in the district of Marche, surrounded by rocks, with an ancient castle, said to be of Roman construction. The place contains 878, and the canton 5148 inhabitants, on a territory of 237½ kilometres, in 18 communes; 33 miles S.S.W. of Liege. N. lat. 50° 9'. E. long. 5° 5'.—Also, a sea-port town of France, and principal place of a district, in the department of the Lower Charente, seated on the Charente. The place contains 15,000, and the canton 17,842 inhabitants, on a territory of 162½ kilometres, in 8 communes. N. lat. 45° 56'. W. long. 0° 52'. This port has excellent docks for building, careening, and refitting vessels, and magazines well replenished with naval stores. It has also a marine academy, and an hospital for seamen; but the adjacent salt-marshes injure its salubrity. In this respect it has been improved by the drying of the marshes by canals. The town was founded by Louis XIV. A.D. 1665; it is elegantly built and fortified, and contains several churches and convents. It has water sufficient, even at low water, to float large vessels, and they are sheltered from all hurricanes, and also secured from all attacks of bomb-vessels. It is also said, that the worm, which is so destructive to ships' bottoms, does not affect them here. The approach to the town up the river is defended by several forts, and is about two leagues from the sea-coast, five from the mouth of the river, and six S.E. of Rochelle.

ROCHEFORT, *La*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of the Vannes; 16 miles E. of Vannes. The place contains 628, and the canton 9837 inhabitants, on a territory of 187½ kilometres, in 9 communes. N. lat. 47° 42'. W. long. 2° 15'.

ROCHEFORT, a town of France, in the department of the Seine and Oise; 4 miles N. of Dourdan.

ROCHEFORT *sur Loire*, a town of France, in the department of the Mayne and Loire, on the S. side of the Loire; 13 miles S.S.W. of Angers.

ROCHEFORT *Sanson*, a town of France, in the department of the Drôme; 12 miles E.N.E. of Valence.

ROCHEFORTIA, in *Botany*, received that name from professor Swartz, in commemoration of a French writer, De Rochefort, of whom we know nothing but that he published, in 1639, *Histoire naturelle et morale des îles Antilles de l'Amérique*, with plates; a work of which a second edition appeared at Rotterdam in 1665, and an English translation, by J. Davies, at London in 1666.—Swartz Prodr. 4. Ind. Occ. v. 1. 551. t. 10. Schreb. 797. Willd. Sp. Pl. v. 1. 1328. Mart. Mill. Dict. v. 4.—Class and order, *Pentandria Digynia*. Nat. Ord. *Dumosa*, Linn. *Rhamnii*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, in five

deep, ovate, obtuse segments. *Cor.* of one petal; tube short, pervious; limb funnel-shaped, in five deep, ovate-oblong, spreading segments. *Stam.* Filaments five, inserted into the mouth of the corolla between the segments, awl-shaped; anthers oblong. *Pistl.* Germen superior, roundish, compressed; styles two, awl-shaped; stigmas simple. *Peric.* Berry? nearly globose, of two cells. *Seeds* few, angular.

Eff. Ch. Calyx inferior, in five deep segments. Corolla funnel-shaped, pervious at the mouth. Fruit of two cells, with several seeds.

1. *R. cuneata*. Wedge-leaved Rochefortia. Willd. n. 1. Swartz Ind. Occ. v. 1. 552.—Leaves wedge-shaped, obovate, undivided.—Native of dry, stony, mountainous places in Jamaica. *Stem* shrubby, three or four feet high, erect, with round, zigzag, subdivided, grey branches, armed with a solitary projecting thorn, near the insertion of each foot-stalk. *Leaves* about three, rarely more, together, in alternate tufts, stalked, generally quite entire, sometimes emarginate, rather rigid, smooth, and somewhat shining, on both sides, of a brownish-green, slightly ribbed; paler beneath. *Footstalks* short. *Flowers* small, greenish or whitish, in dense forked, cymose, terminal or axillary, clusters, shorter than the leaves. *Calyx* downy, as well as the *germen* and *stigmas*. The fruit was only seen in an unripe state by Dr. Swartz, so that he could not determine whether it were a berry or capful.

2. *R. ovata*. Ovate-leaved Rochefortia. Willd. n. 2. Swartz Ind. Occ. v. 1. 554.—Leaves ovate, emarginate.—Native of bushy stony places in Jamaica. A shrub, with round smooth branches. Swartz makes no mention of thorns. The leaves are alternate, stalked, ovate, emarginate at the summit, but otherwise entire, slightly villous, veiny, an inch long. *Flower-stalks* one-fifth only of the length of the leaves, each bearing many flowers in pairs. Unripe fruit like the foregoing.

ROCHEFOUCAULT, FRANCIS, duke of, prince of Marillac, in *Biography*, a well-known writer in the age of Louis XIV. was born in 1613. He distinguished himself as one of the most brilliant young noblemen about the court, and formed a connection with the dukes of Longueville, which involved him in the civil war of the Fronde. At the battle of St. Antoine, in Paris, he signalized his courage, and received a musket shot, which for some time deprived him of sight. When these troubles were terminated, he devoted himself to the pleasures of society and literature. His house was the resort of the best company at Paris, in point of talents and understanding, and his conversation was relished by Boileau, Racine, Sevigné, and La Fayette, and the other literary characters of France. Nor did he only shine by his wit and vivacity; he displayed great firmness of mind under domestic losses (having had one son killed and another wounded at the passage of the Rhine), and under the pain of the gout, with which he was afflicted in his latter years. Mad. de Sevigné speaks of him as "holding the first rank in courage, merit, tenderness, and good sense." In Mad. Maintenon's Letters is the following portrait of the duke. "He had a happy physiognomy, a grand air, much wit, and little learning. He was intriguing, supple, and wary: I never knew a friend more solid, more open, or who gave better counsel. He loved to take the lead. Personal bravery appeared to him a folly, and scarcely did he disguise this opinion; yet he was very brave. He preserved till death the vivacity of his disposition, which was always very agreeable, though naturally serious." The duke de Rochefoucault died with philosophical tranquillity at Paris in 1680, in his 68th year. He made himself famous by a work entitled "Reflexions et Maximes,"

Maximes," many times printed, and translated. Voltaire speaks thus of it: "This little collection, written with that delicacy and finesse which render a style so captivating, had the rare merit of accustoming readers to think, and to give a lively and precise expression to their thoughts." The fundamental principle of this work is, that self-love is the motive of all our actions. It is therefore, perhaps, less the history than the satire of the human race: but it is a satire which, says a writer, pleases, because it flatters malignity, and because it excuses men from the admiration of virtue, by giving it a principle in common with vice, and thereby stripping it of the heroism attributed to it. It seems allowed, says Dr. Aikin, that the writer painted very exactly the world in which he lived, but a lover of mankind will scarcely admit that world to have been a fair example of the species. Misanthropes have taken pleasure in his sentiments, and Swift has made one of his thoughts the basis of his most finished piece, the poem on his own death. The duke also wrote "Memoires de la Regence d'Anne d'Autriche," 2 vols. 12mo. 1713, an energetic and faithful representation of that stormy period, in which he was himself an actor. Gen. Biog.

**ROCHEFOUCAULT, La**, in *Geography*, a town of France, in the department of the Charente, and chief place of a canton, in the district of Angouleme; 12 miles N.E. of Angouleme. The place contains 2,586, and the canton 14,574 inhabitants, on a territory of 252½ kilometres, in 17 communes. N. lat. 45° 46'. E. long. 0° 28'.

**ROCHELLE, LA**, a sea-port town of France, and principal place of a district, in the department of the Lower Charente, with a good harbour. The place contains in the E. and W. divisions 18,000 inhabitants: the canton of the former has 14,636, on a territory of 77½ kilometres, in 7 communes; and that of the latter 13,642 inhabitants, on a territory of 75 kilometres, in 7 communes. In the middle age it was called Rupella and Portus Santonum: it was, before the revolution, the capital of Aunis, and a bishop's see. It was the birth-place of Reaumur, Desaguliers, &c. The town is considerable, having an academy of sciences established in 1732, an hospital, and two suburbs. It is regularly built in a marshy situation; the entrance of its harbour is narrow, and is defended by two towers. The circumference of its ramparts is about three miles. Its manufactures are delft ware, glass, refining of sugar, &c. and its commerce, particularly to the French colonies in Africa and America, was, before the last war, very considerable. In 1361 Rochelle was given up to the English. In the 16th century, the inhabitants joined in the reformation, fortified the town, and held out a siege. In 1622 Louis XIII. in order to compel them to surrender, ordered Fort Louis to be constructed at the entrance of the harbour, and in 1628 a mole was raised which surrounded it, in order to prevent the town from receiving any succour by sea. The besieged were at length compelled by famine to surrender; in consequence of which it was deprived of its privileges and its fortifications demolished; but in the reign of Louis XIV. they were repaired by Vauban. N. lat. 46° 9'. W. long. 1° 3'.

**ROCHELLE, New**, a town of America, belonging to the state of New York, in Long island sound; 6 miles N.N.E. of West Chester. N. lat. 41° 54'. W. long. 73° 46'.

**ROCHELLE Sal.** See *RUPELLENSIS Sal.*

**ROCHEMAURE**, in *Geography*, a town of France, in the department of the Ardeche, and chief place of a canton, in the district of Privas; 9 miles S.E. of Privas. The place contains 1110, and the canton 4372 inhabitants, on a territory of 107½ kilometres, in 8 communes.

**ROCHESTER**, a city in the hundred of Rochester, lathe of Aylesford, and county of Kent, England, is situated on an angle of land formed by the current of the river Medway, at the distance of 8½ miles N. from Maidstone, and 29 miles E. by S. from London. According to the population census of 1811, it contained, in conjunction with the adjoining town of Chatham, 3838 houses, and 21,722 inhabitants.

*Historical Events.*—Rochester is said to have been originally founded by the ancient Britons, who gave it the appellation of Dwr-bryf, which signifies "a swift stream," in allusion to the rapidity of the Medway at this part of its course. When the Romans established themselves in Albion, it became one of their stipendiary stations, and was denominated by them Durobrivæ, or Durobrivis, afterwards contracted to Roibis. These facts are evidenced by the Itinerary of Antoninus, as also by the Peutingerian Tables, and receive strong confirmation from the frequent discoveries of Roman remains, which have been made at different periods within the area of the present city. During the government of that people, however, its history is completely barren; nor did it attain any celebrity for more than a century after the arrival of the Saxons, who altered its name to Hrof-ceaster, whence its modern designation is derived. Ethelbert, king of Kent, who was converted to the Christian faith A.D. 597, first erected a church here, and constituted the town a bishop's see. Still, however, it was regarded chiefly as a military station, and hence is styled by Bede "a castle of the Kentish men." In the year 676, Ethelred, king of Mercia, pillaged Rochester, as did Ceadwalla, king of Wessex, within a few years of the same period. The Danish invaders likewise frequently plundered it, particularly in 839, when they sacked the city and committed many cruelties. In 885 they besieged it again, but were effectually kept in check by the inhabitants, till the great Alfred arrived with his army, and drove them back to their ships. About a century afterwards, Ethelred, king of Kent, met with a similar reception, and being frustrated in his attempt upon the city, gratified his vengeance by laying waste all the lands belonging to the see. But these sieges were trivial to what the inhabitants suffered from the Danes in 999, when the city was pillaged to the uttermost, and all the inhabitants who remained in it were put to death. From that period Rochester seems to have continued mostly in possession of the Danes till the death of Canute the Great. In the time of Edward the Confessor it belonged to the crown; and as part of the royal domains was seized by the Conqueror, by whom it was granted to his half-brother, Odo, bishop of Baieux, on whose disgrace, in 1083, it reverted to the monarch. Henry I. farmed it out to the citizens at the yearly rent of 20*l.*, which was paid by the præpositus or bailiff. He also granted to bishop Gundulph, and to the church of Rochester, an annual fair to be held on the eve and day of St. Paulinus, together with various rights and immunities. In the same reign, on the 11th of May 1130, while Henry himself, the archbishop of Canterbury, and other prelates, and many of the nobility were at Rochester, most of its buildings were consumed by fire. A similar misfortune befell it in the year 1137, and again in April 1379. These several calamities retarded the prosperity of the city; and the intestine commotions happening soon afterwards, it did not regain any great degree of consequence till the reign of Henry III. This monarch repaired, or rebuilt, the city walls, and invested it besides with a deep fosse. In 1251 the same prince held a solemn tournament here, which was attended by most of the English nobility, and by a great concourse of foreign knights. In the time of the wars between

## ROCHESTER.

tween York and Lancaſter, Rochefter ſuffered much from the arms of the contending parties, and was more than once viſited by the plague. Henry VIII. was twice here, once in company with the emperor Charles V. and again when he came hither to meet his confort, Ann of Cleves. During the reign of queen Mary ſeveral individuals ſuffered martyrdom here for their religious opinions. Queen Elizabeth, her ſucceſſor, lodged upwards of a week at Rochefter; and this was the firſt city in which Charles II. was publicly received, after his reſtoration to the throne in 1660. In 1665, Rochefter was viſited with the ſame plague, which committed ſuch dreadful havoc among the inhabitants of the metropolis. From that period nothing worthy of hiſtorical record has occurred.

*Municipal Government.*—Rochefter probably poſſeſſed a corporate community even in the time of the Saxons, but its nature cannot now be preciſely aſcertained. The firſt Norman monarch who granted to the inhabitants any privileges by charter, was Henry II. This prince gave them the city “in fee, or perpetual ferm, for 20*l.* ſterling *per annum*, to hold of him and his heirs for ever, with all the appurtenances, liberties, and free cuſtoms; and that they ſhould have a guild merchant, and ſeveral other privileges and immunities.” Theſe advantages were ſtill further increaſed by Richard I., who directed his writ to the bailiff, and the whole hundred of Rochefter, ordaining, “that no one, except his ſervants, ſhould purchaſe victuals in the city till the monks of St. Andrew had been firſt ſerved.” This right was afterwards ſo far extended, that even the ſervants of the monarch were forbidden to make a prior purchaſe; and the monks continued to enjoy the privilege thus given till the diſſolution. Henry III. not only confirmed to the citizens all former grants, but remitted to them a portion of their annual fee-ferm, and declared they were to be “exempt from toll, laitage, ſtallage, and murage, throughout England and the ſea-ports, and ſhould have a free market within their city, and the return of all writs whatſoever.” Theſe privileges were renewed by Richard II. in 1378; by Henry VI. in 1438 and 1446; and by Edward IV., who further extended the bounds of the city, and ordained that the corporation ſhould be ſtyled “the mayor and citizens of Rochefter.” Henry VIII. was the next monarch who confirmed the privileges of Rochefter; and his ſucceſſors, to the time of Charles I., ſeverally did the ſame. By the laſt mentioned monarch, the corporation was made to conſiſt of “a mayor, twelve aldermen, (of which latter number the mayor was to be one,) twelve aſſiſtants, or common council-men, a recorder and town-clerk, two chamberlains, a principal ſerjeant at mace, a water-bailiff, and other inferior officers.” Under this charter the city is now governed; and by virtue of it, the mayor is elected annually on the Monday previous to St. Matthew’s day. The mayor and citizens hold a court of admiralty once a-year, for regulating the oylter-fiſhery in thoſe creeks and branches of the river Medway which are within their juriſdiction. Here are alſo held the county aſſiſes, alternately with Maiditone; likewise the petty ſeſſions for the north diſtion of the lathe of Aylesford. The market-day is Friday, weekly; and there are two annual fairs, on the 30th of May and the 11th of December. Rochefter ſends two members to parliament, and has done ſo ever ſince the 23d year of Edward I. The right of election is veſted in the freemen, who are about 630 in number. Many of the repreſentatives have been naval officers, diſtinguiſhed for brilliant achievements in the cauſe of their country.

*Public Structures.*—The buildings of a public deſcription

that chiefly demand attention, are the caſtle, the cathedral, the churches, the town-hall, and the bridge, each of which is entitled to ſeparate notice.

The preſent caſtle of Rochefter was one of thoſe founded by William the Conqueror, to keep in awe his newly acquired ſubjects; but there ſeems every reaſon to believe that a prior one exiſted on the ſame ſite, as frequent mention is made of the “*Caſtrum Roſſenſe*” in the Saxon annals. The Conqueror, indeed, is ſaid, by ſome hiſtorians, to have only repaired the former ſtructure. Whatever it might be, however, he committed to Odo, biſhop of Baieux, the execution of the new work, and the cuſtody of the fortrefs; but that prelate proving unworthy of his truſt, he was afterwards ſeiſed, and ſent as a priſoner to the caſtle of Rouen, in Normandy, where he continued till the acceſſion of William Rufus, who reſtored him to his dignities and poſſeſſions; a favour which he ſhortly after ungratefully repaid, by raiſing an inſurrection in favour of the king’s brother, Robert, duke of Normandy. Rufus, upon this, laid ſiege to Rochefter caſtle, and having forced the gariſon to ſurrender, baniſhed the biſhop from his dominions. During this ſiege the buildings ſuſtained conſiderable injury, which the king enjoined biſhop Gundulph and the prior of Rochefter to repair, perhaps on account of their having ſhewn ſome attachment to the rebellious cauſe. Gundulph accordingly not only renovated the walls, but laid the foundation of the great ſquare tower, which yet perpetuates his name, and entitles him to rank among the moſt eminent architects of Anglo-Norman times. About twenty years after this prelate’s death, the cuſtody of Rochefter caſtle was granted to William Corboyl, then archbiſhop of Canterbury, and to his ſucceſſors; but this grant was reſumed by Henry II. on his quarrel with the celebrated Thomas a Becket. In the reign of king John, this fortrefs was ſeiſed and gariſoned by the rebellious barons, and having been beſieged by the king, was taken, after a reſiſtance of three months. Lewis, the dauphin of France, who came over to the aſſiſtance of the nobles, however, reduced it again in ſubjection to the barons, by whom it was held till the acceſſion of Henry III., when it was ſurrendered to the crown, and granted for life to Hubert de Burgh, earl of Kent, and juſticiary of England, who was commanded to repair the buildings. The king’s favour afterwards declining, Hubert was diſpoſſeſſed; and Stephen de Segrave, John de Cobham, Nicholas de Moels, William de Say, and Robert Waleran, were, in ſucceſſion, appointed governors of the caſtles of Rochefter and Canterbury. About the year 1264, after the king had occaſioned much diſcontent among his barons, by his reſuſal to comply with the ſtatutes of Oxford, he greatly ſtrengthened the fortifications of this caſtle, and furniſhed it with every thing neceſſary to ſuſtain a ſiege. Roger de Leybourne, who was conſtituted chief conſtable, had under him John, earl of Warren and Surrey, and other noblemen. Shortly afterwards, Simon de Montfort, chief of the aſſociated barons, marched hither to beſiege the caſtle, on which occaſion ſeveral ſevere conteſts happened in this vicinity. Montfort ſucceeded in getting poſſeſſion of the city, but failed in his attacks upon the caſtle, the ſiege of which he was eventually compelled to abandon. After this event, little more occurs in the hiſtory of this caſtle, than the names of thoſe to whom its cuſtody has been entrusted. Edward IV. was the laſt monarch who paid any attention to the ſtate of its buildings, he having “repaired the walls, both of the caſtle and city, about the eleventh year of his reign.” Since then they have been alike neglected, and have gradually fallen to their preſent ſtate of decay. Several

## ROCHESTER.

veral estates in this county hold of Rochester castle by the ancient tenure of castle-guard. On St. Andrew's day, old style, a banner is hung out at the house of the receiver of rents; and every tenant who does not then discharge his arrears, is liable to have his rent doubled, on the return of every tide of the Medway, till the whole is discharged.

Rochester castle stands at the south-western angle of the city, on an eminence rising abruptly from the river Medway, which preserves it from attack on the west, whilst its south, east, and north sides are defended by a broad and deep ditch. The outward walls, which formed an irregular parallelogram, 300 feet in length, were strengthened by several square and round towers; but these, as well as the walls themselves, are now verging to a state of ruin. The most perfect are on the east side, and at the south-east angle; that at the angle was semicircular, and rose boldly from the ditch, which is now almost filled up. The principal entrance was on the north-east, and was defended by a tower-gateway, with outworks at the sides. The keep, or great tower, already mentioned as founded by bishop Gundulph, occupies the south-east portion of the castle area. It is of a quadrangular form, 70 feet square at the base, and is so planned, that its angles correspond with the four cardinal points of the compass. The walls on the outside are built inclining inwards from the base, and in general measure twelve or thirteen feet thick. Near the centre, on each side, is a pilaster buttress, ascending from the base to the roof; and at the angles are projecting towers, three of them square, and the fourth semi-circular, which rise twelve feet above the roof. The entrance to this part of the castle was most difficult and intricate, and displayed much architectural ingenuity. "The first ascent was by a flight of twelve steps, leading to an arched gate and covered way; beneath which a flight of seven steps led forward to a draw-bridge, that connected with the arched gateway of the entrance tower; this opened into a vestibule, between which and the keep there were no other avenues of communication than by a third arched passage in the thickness of the wall. This latter, being the immediate inlet to the body of the keep, was defended by a massive gate and portcullis, the hinges and grooves of which yet remain; and in the roof are openings for the purpose of showering down destruction on the assailants."

The interior of the keep is divided into two nearly equal parts by a strong wall, with arched door-ways of communication on each floor. In the centre of this wall is a circular hole for a well of considerable depth, neatly wrought, and open from the bottom to the very top of the keep. This tower consisted of three floors, independent of the basement story; but these floors were removed when the castle was dismantled in the reign of James I. The lowest apartments were two dark and gloomy rooms, in which the garrison stores were probably deposited. At the north-east angle is a circular winding staircase, which ascends to the summit; and near it is a small arched doorway, leading to a narrow vaulted apartment underneath the little tower, supposed to have been a dungeon for criminals. The first floor appears to have been allotted for the accommodation of servants and inferior attendants; the second floor contained the state apartments; and the third was designed for a chapel, and for bed-rooms for the family. The roof of the keep is now entirely destroyed; but it most probably consisted of a platform on a level with the top of the wall within the parapet; the latter was about five feet high, and had embrasures about two feet wide. The four towers at the angles were raised another story, and had also small platforms, with parapets and embrasures. These, as well as the first-mentioned platform, commanded a very extensive view over the

whole city, the river Medway, and the adjacent country; so that no enemy could approach within the distance of several miles without being discovered.

*Cathedral and Priory.*—The see of Rochester, though one of the smallest in England, derives considerable consequence from its antiquity. It was established, and a church built, as early as the year 600, by Ethelbert, king of Kent; who, at the same time, attached to the church a priory for secular canons, and dedicated it to the honour of St. Andrew. The first prelate of this see was Justus, a man of eminent learning and integrity, who had been sent from Rome to assist in the conversion of the Saxons to Christianity. He was installed by St. Augustine, the apostle of Britain, and first archbishop of Canterbury, in the year 604, from which period the episcopal dignity of Rochester has been held in succession by ninety-four bishops, many of whom were eminent for their talents, piety, benevolence, and extensive acquirements. Paulinus, the third bishop, was reputed a faint, and his memory was held in high estimation during several centuries. Ithamar, the fourth bishop, was the first Englishman who held a prelate in Britain. Tobias, the ninth bishop, is highly extolled by Bede, and other writers, for his literary attainments, and particularly for his intimate knowledge of the Greek, Latin, and Saxon languages. These three prelates were all interred in the ancient cathedral, and are the only bishops known to have been so honoured of all the twenty-five who presided previous to the Conquest. At the era of that event the see appears to have been fast verging to entire dissolution; but its impending fate was soon after arrested by Lanfranc, archbishop of Canterbury, who raised Ernout, a monk of Bec, in Normandy, to the bishopric, for the avowed purpose of improving its affairs. That bishop, however, died in the first year of his prelate, and was succeeded by Gundulph, another monk of Bec, who proved a most active agent in the re-establishment of the see. He not only recovered the alienated estates of the bishopric, but, pulling down the old cathedral, he erected a spacious and magnificent edifice in its stead. He likewise rebuilt the priory, and placed therein twenty monks of the order of St. Benedict, upon whom he bestowed extensive privileges and possessions. Gundulph had for his successor Ernulph, abbot of Peterborough; who composed the "Textus Roffensis," a work replete with information on matters of antiquity. He was likewise distinguished as an architect, having, besides his works at Canterbury and Peterborough, built the dormitory, and refectory, and the chapter-house at Rochester. He was succeeded by John, archdeacon of Canterbury, in whose time the monastery was unfortunately destroyed by fire; an event which occasioned the temporary dispersion of the monks. On the re-erection of the priory, however, they were again collected, and, through the exertions of bishop Ascelin, recovered such of their possessions as had been alienated by the cupidity of his predecessor, John, a Norman bishop, who had obtained this see on the death of his namesake above-mentioned. Ascelin's successor was Walter, brother to Theobald, archbishop of Canterbury, who was elected by the monks of Rochester. This bishop assisted at the coronation of Henry, eldest son of Henry III., on which account he was excommunicated by Thomas à Becket. During his prelate, the cathedral sustained heavy damages by fire. This bishop died in 1182, and was succeeded by bishop Waleran, who, as well as his successor, Gilbert de Granville, was constantly engaged in litigations with the prior and monks, which were at length settled by solemn adjudication in the year 1207: notwithstanding this, however, the monks thought proper to display their hatred to bishop Granville, by refusing burial to his remains in the cathedral;

## ROCHESTER.

and on being frustrated in their resistance, they hastened the interment, that it might take place before the interdict which the nation then lay under was removed. This prelate rebuilt the bishop's palace, which had been burnt down by the fire above noticed; and also erected a cloister of stone for the monks: but the re-edification of the cathedral made very slow progress, as we find it remained unfinished till the year 1240, when Richard de Wendover held the bishopric. He had been elected to the see by the monks, in opposition to the claims of patronage maintained by Edmund, archbishop of Canterbury, who appealed on the subject to the court of Rome, but without success. On his death, in 1250, Laurence de St. Martin was advanced to the episcopal dignity, and held it till 1274, when he died, and gave place to Walter de Merton, to whom his country is indebted for the foundation of Merton college, at Oxford, which is considered to be the "first literary community in this kingdom that had the sanction of a royal charter." His immediate successors were, John de Bradfield, who died in 1283; Thomas de Ingelthorpe, who died in 1291; and Thomas de Woldham, who died in 1316. On the decease of the latter, Hamo de Hethe obtained the bishopric. He was a very active prelate, and conferred considerable benefits on the priory and the church. His successor was John de Shepey, who had been a monk in the priory, and was a man of great learning and abilities. Some sermons attributed to him are still extant in New college, Oxford, and there are in the king's library two MSS. of his on legal subjects. He died in 1360, when William Wittesley was consecrated bishop, but was soon afterwards translated to the see of Worcester. Thomas Trilleck next obtained the bishopric, and after him Thomas Brinton, confessor to king Richard II. and the fifty-first bishop of this see. Richard Young, the third in succession after him, met with great difficulties in obtaining possession of his bishopric, owing to the death, first of pope Boniface, by whose mandate he was translated from Bangor, and afterwards of his successor, pope Innocent. At length, however, he was installed, in May 1407, and held the see till 1418, when he was removed by death, and was succeeded by John Kemp, who subsequently became bishop of Chichester and of London, and archbishop of York and of Canterbury. His successor was the learned John Langdon, who was distinguished for his extensive knowledge of history and antiquities, and was author of a chronicle of England. On his death, which happened in 1434, while he was attending the council at Basil on the part of Henry VI., Thomas Brown, D.D. was elected to the vacant see. John Lowe, the fifty-ninth bishop, was provincial of the order of Augustine friars. He held the bishopric twenty-three years, and is supposed to have rebuilt the palace at Rochester. He died in 1467, and was succeeded by Thomas de Rotherham, subsequently bishop of Lincoln, lord chancellor, and archbishop of York. The next bishop of note was the unfortunate John Fisher, who was beheaded in 1535, by order of Henry VIII. for maintaining the supremacy of the pope in ecclesiastical affairs. His successor was John Hilsey, D.D. a controversial writer of considerable eminence, who died in 1538. Two years afterwards, the priory here was surrendered to the king; and in 1542 a new foundation charter was granted, by which a collegiate body was established in the church, to consist of a dean, six prebendaries, six minor canons, a deacon and sub-deacon, six lay clerks, a master of the choristers, eight choristers, one grammar master, twenty scholars, two sub-sacristis, and six poor bedesmen," besides inferior officers. In the new establishment, Walter Phillips, the prior of the late convent, was made first dean of the cathedral; and Nicholas

Heath, D.D. was the first reformed bishop of the see. From his time to the present period, twenty-five bishops have been advanced to the episcopal dignity of Rochester, among whom the most noted were the pious Ridley, who suffered along with bishop Latimer at Oxford; Francis Atterbury, who was exiled for treasonable correspondence in 1723; and the late bishop Horsley, one of the most erudite divines the church of England can boast of.

The situation of Rochester cathedral is at a short distance south from the High-street, and east from the castle. It is of a cruciform shape, and is divided into a nave, aisles, two transepts, and a choir, with a low tower and spire rising at the intersection of the nave and great transept. This edifice evidently appears, from the different styles of its architecture, to have been the work of different eras. The chief part of the nave and west front display the massive character of the early Norman age. The west entrance is particularly deserving of attention, and must have been, when entire, a most magnificent piece of workmanship. The arch which forms this entrance is semi-circular; and is supported on each side by several columns, two of which are cut into statues, representing king Henry I. and his queen Matilda, the patrons of the founder, bishop Gundulph. The capitals of all the columns are composed of wreathed foliage, mixed with the heads of birds, and other animals. The lintel of the door, immediately under the arch, exhibits a figure, probably designed to represent the Saviour, attended by angels, and the attributes of the four evangelists. The mouldings of the arch, and the transoms, are charged with varied sculpture. The remaining parts of the cathedral are comparatively plain in their exterior. Entering the nave by the western door, the massive Norman style is conspicuous in the first five columns, and half of the sixth, on each side, all of them supporting circular arches, decorated with zigzag mouldings, above which is a series of smaller arches, having over them arches, corresponding, both in size and ornament, with the larger ones beneath. Still higher are two ranges of obtuse-pointed windows, each divided into three lights. The roof is of timber, with knees supported on corbels, the fronts of which are carved into figures of angels sustaining shields, on which are painted the arms of the city, the see, and the priory of Rochester, as well as those of the archbishopric and cathedral of Canterbury. The west wall appears to have been divided into ranges of niches, some of them crowned with arches, having plain and billeted mouldings, supported on small three-quarter columns, with fluted capitals: others, having neither pillar nor capital, are decorated with zigzag mouldings, continued down the sides of the recesses. The alterations made in Gundulph's design by the introduction of the present west window, are clearly to be seen in the abrupt termination of the different ranges of these niches, some of them having been cut through the centre. The two easternmost arches of the nave, on each side, exhibit a very different style of architecture to the preceding; these being in the pointed style, with deep grooved mouldings, rising from clusters of slender columns. The great tower is supported by four obtusely-pointed arches, resting on pieces of solid masonry, which are environed by slender columns of Petworth marble. The west transept is in the pointed style; but, from having been erected at different periods, the architecture is somewhat dissimilar. In the upper part of the north end is a triforium, behind which are lancet windows, each having a screen in front, divided into three arches of unequal height; the vaulting is of stone, groined, with a plain grooved moulding: several of the lesser pillars and imposts of arches are supported by corbel

corbel heads, chiefly of monks, which display a degree of strength of feature and expression, evincing an advanced state of the art of design. The fourth end of this transept principally varies from the other in its superior lightness: like that, it has a triforium in the upper story, with lancet windows behind screens. The roof is of timber framework, in imitation of vaulting. Under a large arch, on the west side, is an opening into the chapel of St. Mary, a structure probably erected in the reign of Henry VII. It measures forty-five feet in length, and thirty-five in breadth, and exhibits on its south and west sides five spacious windows, under obtuse arches, and divided by mullions. In this chapel the consistory court of the diocese is held; and many of the bishops are buried within it. The choir is entered from the nave by an ascent of ten steps, leading through an arch, in an unornamented stone screen, which sustains the organ and organ gallery. The style of building in this part of the church is uniform in its character; neat, lofty, and solid, though not heavy. The whole consists of two tiers of pointed arches, decorated with grooved mouldings, and resting upon slender columns of Petworth marble, with plain capitals. All the windows are lancet-shaped, and are formed of single lights, except those nearest to the altar, which are divided by mullions, and appear to have been formerly filled with painted glass. The east transept of the church has two aisles, over which are apartments, (ascended to by circular winding staircases in the wall,) in which were deposited the vestments, and sacred utensils appertaining to the altars and shrines of St. William, St. Paulinus, and others, in the choir. The northern division of this transept is still denominated St. William's chapel, from the popular saint so named, whose remains were there enshrined; and to the number and value of the oblations made at whose altar the present choir owes its origin. The crypt, which extends beneath the two last mentioned portions of the church, has been thought by some to be of Norman structure; but more intelligent antiquaries assign it to the architect of the choir and upper transept, which were built by William de Hoo, in the reign of Henry III. The pointed arches in the windows and entrances are evidences of the truth. Running parallel with the fourth side of the choir is the chapter-house, which contains the library, and is entered by a richly sculptured door-way. In a large hollow between the inner mouldings is a range of human heads and flowers, in alternate succession. Beyond these, and rising above each other in detached recesses to the centre of the arch, are six whole length figures, two of which are conjectured to represent Henry I. and his queen Matilda, and the others the bishops Gundulph, Ernulph, Laurence de St. Martin, and Hamo de Hethe, to the last of whom the erection of this door-way is attributed. Over these figures are smaller ones of angels, two on each side, apparently singing praises and glorifying the Saviour, who is represented standing naked under a canopy in the centre of the arch. The library, besides an excellent collection of printed books, contains several curious and valuable MSS. among which are the original copies of the *Textus Roffensis* and the *Cultumale Roffense*.

Rochester cathedral extends in length from east to west 306 feet, of which 150 are included in the nave and 156 in the choir. The breadth of the nave, with the side aisles, is 75 feet, and that of the choir is nearly the same. The western transept measures 122 feet, and the eastern one 90 feet long. The width of the west front is 94 feet, and the height of the great tower 156 feet. Several of the monuments in this church are curious, both from their antiquity and their workmanship. In the fourth of the choir is a plain stone chest, supposed to contain the remains of bishop Gundulph, and near it is another, on the top of which is sculp-

tured, in high relief, the figure of a bishop in pontificalibus, designed to represent Thomas de Ingelthorpe, the 44th bishop of the see. A third stone chest, of a similar description, is thought to be the tomb of bishop Laurence de St. Martin, who obtained the canonization of St. William. All these chests are constructed of Petworth marble: several others of them are dispersed throughout the cathedral. On an altar-tomb, beneath a double pointed arched canopy, variously ornamented, is a full-length portraiture of bishop Walter de Merton, whose remains are deposited beneath. Another altar-tomb, in St. William's chapel, commemorates bishop Lowe; and near it are the monuments of bishop John Warner and two others of his family. On the north side of St. Edmund's chapel, entering into the crypt, is a headless episcopal figure, supposed to have represented bishop John de Bradfield, who died in the year 1283; and in the narrow aisle leading to St. William's chapel, is a monument attributed to bishop Hamo de Hethe. The other persons who have monuments here are, Richard Watts, esq. recorder of the city, who had the honour of entertaining queen Elizabeth at his seat called Satis; John, lord Henniker, and his lady, the former of whom died in 1803, and the latter in 1792; sir Richard Head, and the Rev. Samuel Denne, the learned compiler of the "Memorials" of this cathedral, inserted in the *Cultumale Roffense*.

Adjoining to the cathedral, on the south, are the remains of the chapter-house and cloister belonging to the priory, which exhibit a very beautiful series of Norman arches and ornaments, but in a state of great dilapidation. The doorway of the chapter-house lies under a richly ornamented arch, having on each another of equal elegance, supported on short thick columns with flowered and figured capitals, and displaying an unusual variety of mouldings, zigzag, quatrefoil, and billeted. The mouldings of the southernmost arch unite with those of a smaller arch, belonging to the cloister, and these again with the mouldings of a second highly enriched door-way, the space between the transeom of which and the inner moulding exhibits the mutilated remains of an historical sculpture. An arch, rising from two three-quarter columns, and intersected by two others springing from a central column, connects this door-way with a third, likewise rich in ornaments, though less so than the others. Gundulph's tower stands on the north side of the cathedral between the transepts. The masonry of this building is extremely solid, the walls being ten feet in thickness, though the entire building is only 40 feet square. The angles are strengthened by pilaster buttresses, and the windows have semicircular arches. The precincts of this cathedral appear to have occupied nearly half the area contained within the walls of the city. There were three gates leading into them, *viz.* the Cemetery gate, St. William's gate, and the Prior's gate; the first and last of which are still remaining. Only a few traces of the offices of the monastery now exist separately, but considerable parts of their walls are incorporated into other buildings. The porter's lodge consists of a small embattled tower, with a pointed archway in the centre. The site of the bishop's palace, erected by Gundulph, is occupied by a range of modern houses; and on that of the prior's lodge stands the present deanery.

Rochester had formerly four churches, besides the cathedral, which were dedicated to St. Nicholas, St. Margaret, St. Clement, and St. Mary, but the last is now totally demolished, and St. Clement's is only to be discovered as forming part of some houses on the north side of the High-street, near the bridge. The church of St. Nicholas was built in 1421, and consists of a nave, aisles, and a chancel, with an embattled tower at the north-west angle. The

windows are large and pointed; each being divided into three lights, with crockets above. St. Margaret's church is only remarkable for its fine situation, on a lofty eminence, to the southward of the High-street. The town-hall stands on the north side of the same street, and was erected about the year 1687. In the lower division of this structure is the city prison; and in the higher, the hall, a large and lofty room, containing full-length portraits of king William and queen Anne, and of several persons of distinction, connected with the city. The bridge over the Medway, here, was constructed in the reign of Richard II. by sir Robert Knolles, and John, third baron de Cobham, who not only defrayed the expence of its erection, but also left a considerable estate for its repair. For height and strength, this structure is allowed to be superior to any in England, with the exception of the bridges in the metropolis. It measures 560 in length, but is only 14 feet broad between the parapets. Its arches are eleven in number, but of these, three have been rebuilt in modern times.

The charitable institutions in this city are, St. Catharine's hospital, a grammar-school, an almshouse for the relief of poor travellers, and a free-school. The hospital was founded and endowed in 1316, by Simond Potyn, who represented this city in seven parliaments, for the maintenance of twelve poor people, who have an allowance of coal, candle, and money, annually.

The grammar-school was founded by king Henry VIII., for twenty scholars, to be called "King's scholars," with an upper and under master; together with four exhibitions to the universities. The almshouse, which stands on the north side of the High-street, was built in the reign of queen Elizabeth, the proprietor of Satis, before-mentioned, who left estates for its support. The founder of the free-school was sir Joseph Williamson, knt., who died in 1701, and bequeathed 5000*l.* to be expended in the erection of a suitable building, and in the purchase of lands and tenements to maintain two masters, and defray the incidental expences of the establishment. The History and Antiquities of Rochester and its Environs, &c. 8vo. Rochester, 1772. The History and Topographical Survey of the County of Kent, by Edward Hasted, F. R. S. and S. A., Canterbury, 4 vols. folio, 1778, reprinted, &c. in 8vo. 1797. History of Kent, by John Harris, D. D. F. R. S. folio, Lond. 1719. Registrum Roffense, and Custumale Roffense, by John Thorpe, D. D. Beauties of England, &c. by E. W. Brayley, vol. viii.

ROCHESTER, a township of America, in the county of Windsor and state of Vermont; containing 911 inhabitants.—Also, a township of Plymouth county, Massachusetts, 52 miles S. of Boston; containing 2954 inhabitants.—Also, a township in Strafford county, New Hampshire, on the W. side of the N. branch of Piscataqua river; 22 miles N.W. of Portsmouth; incorporated in 1722, and containing 2118 inhabitants. One term of the court of common pleas is held annually in this town.—Also, a township in Ulster county, New York, extending W. to Delaware river; about 12 miles W. of Esopus.—Also, a township of Upper Canada, on lake St. Clair, between Tilbury and Maidstone.

ROCHET, or ROCKET, a lawn garment, worn by bishops and abbots, resembling a surplice, except in this, that the sleeves are gathered at the wrists; whereas the surplice is quite open. This was one of the sacerdotal vestments; and in that respect differed from a surplice in that it had no sleeves.

Menage derives the word from the Latin *rochettus*, a diminutive of *rocchus*; used in writers of the lower Latin for *tunica*, and formed originally from the German *rok*. The regular canons of St. Augustine also wear rochets under their copes.

ROCHETS also denote the mantles worn on days of ceremony, by the peers sitting in the English parliament.

Those of viscounts have two bands, or borders, and a half; those of earls, three; those of marquises, three and a half; and those of dukes, four.

ROCIET, the name given to a fish, otherwise called *cuculus*, and *red-gurnard*. See GURNARD.

ROCHETTA, in the *Glass Trade*, another name for polverine.

ROCHETTA, in *Geography*, a town of France, in the department of the Maritime Alps; 16 miles N.E. of Nice.

ROCHETTE, LA, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of Chambery, on the Galon; 10 miles S. E. of Chambery. The place contains 855, and the canton 9092 inhabitants, on a territory of 85 kilometres, in 18 communes.—Also, a town of France, in the department of the Forests; 4 miles S.S.E. of Dierich.

ROCHFORD, a market-town, in a hundred of the same name, and county of Essex, England, is seated on the bank of a small rivulet, called the Brooinhill, at the distance of 16 miles S.E. of Chelmsford, and 39 miles E. of London. The petty sessions for Rochford division of Essex are held here. The privilege of holding markets was granted to this town by king Henry III., and confirmed by Edward I. The market-house is a mean structure of timber. The market-day is Thursday, weekly; and there are annual fairs on Easter Tuesday, and the Wednesday next after the 29th of September. None of the buildings in the town are worthy of notice. The parish church, which stands about half a mile to the westward, is a plain edifice, with a lofty brick tower at the west end. Near it stands Rochford-hall, the manor-house. It is a large and stately building, for some time successively the seat and residence of the Rochfords, the Botelers, earls of Ormond and Wiltshire, sir Thomas Bullen, and Richard, lord Riche. This town gives the title of an earl to the family of Nassau. The parish contains, according to the population returns of 1811, 190 houses, and 1214 inhabitants.

The manor of this town was held by Suene at the time of the Domesday survey; and now is vested in the Long family of Wantstead park. A singular custom, called the Lawless-court, appertains to this manor; and is said to have originated in a conspiracy against the lord of the manor; but detecting it, he ordained as a punishment, that the tenants should ever afterwards assemble, at a certain hour of the night, on the same spot where the conspirators met, and do homage for their lands. The place is called King's-hill, where they were to assemble at midnight on the first Wednesday after Michaelmas day, and transact all their business in whispers, and record the minutes with coal, instead of pen and ink. This ridiculous custom was, till lately, continued. About four miles S.W. is Hadleigh Cattle, consisting of some bold ruins; and near it is Southend, a noted watering-place. See SOUTHEND.

Raleigh, in this vicinity, though now an inconsiderable village, was formerly a market-town, and the head of the barony of Suene, a powerful Anglo-Saxon Dane, who is reported to have built a castle here, of which some important earth-works still remain. These consist of a mound, of an oval shape at the base, which is environed by a double ditch and rampart, and is further secured by additional

tional embankments on the east side. The principal ditch is nearly fifty feet wide, and appears to have been originally of great depth. The church of Raleigh is a handsome building, in the pointed style of architecture, and contains a very ancient tomb, of beautiful "Gothic" workmanship, but without any inscription to determine the name of the person it was designed to commemorate.

About three miles to the N.W. of Rochford, on the summit of a hill, stands the remains of a very ancient church, supposed to be the same which Simeon Dunelmensis states to have been founded by Canute and Turkill in memory of the victory obtained by them over king Edmund Ironside, within the adjoining parish of Affingdon or Ashingdon. The tower is a low massive octagon, supported by strong buttresses; and in the interior are five thick columns with slightly ornamented capitals, dividing the nave from a north aisle. At Canewdon, to the eastward of Ashingdon, is an ancient encampment, of an oblong form, which probable conjecture attributes to the Danes. Its area contains about six acres of ground. The History and Antiquities of the County of Essex, by Philip Morant, M.A. 2 vols. folio, 1768, London. Beauties of England and Wales, vol. v. by E. W. Brayley and John Britton.

ROCHLITZ, a town of Saxony, in the circle of Leipzig, on the Mulda; containing three churches and a citadel, and a manufacture of cloth, stuffs, and linen; 20 miles S.E. of Leipzig. N. lat.  $51^{\circ} 8'$ . E. long.  $12^{\circ} 41'$ .

ROCHOIS, LA, in *Biography*, one of the first singers in Lulli's famous operas, whose abilities were not very itipendous, if we may judge of them by the songs which he had to execute. Good voices and good action seem to have constituted the principal merit of this singer. Many of them were brought from remote provinces of the kingdom, before they had any knowledge of music, and were taught their parts by Lulli himself and his father-in-law, Lambert, merely by the ear. But Lulli not only taught his vocal performers to sing, but to act; and sometimes gave instructions even to the dancers. The celebrated La Rochois, we find, had no other master in singing than the opera composer, Lulli. *Hist. de la Mus. par Bonnet*, t. iii. p. 207 and 209.

ROCHSBURG, in *Geography*, a town of Saxony, in the lordship of Schonburg; one mile E. of Penig.

ROCHSTADT, a town of Westphalia, in the principality of Halberstadt; 10 miles E. of Halberstadt.

ROCHUKE, a town of Bulgaria, situated on the banks of the Danube, at the foot of a hill which continues for several miles near the river, and is covered with vineyards. It is a large and populous town, about the size of Liverpool.

ROCITO, a town of Naples, in Capitanata; 7 miles S. of Volturara.

ROCK, in *Geology*, a large mass of stone, forming part of the solid covering or crust of the globe. In common language, rocks are the bare projecting stony masses that rise above the level of the ground or sea; but the geologist denominates every bed of stone that composes the compact part of our planet a rock, whether it be elevated to view, or buried deep under the surface.

The composition, structure, and arrangement of rocks comprise a most important part of the natural history of the earth, which is now beginning to engage the attention of philosophers in various parts of the world. Numerous and extended observations have greatly enlarged our knowledge of facts, and exposed the fallacy of many of those unfounded distinctions and premature generalizations, which, dignified

with the name of systems, have retarded the progress of science.

In the earliest periods of civilization, when stone began to be employed for purposes of architecture or sculpture, it must have been immediately perceived that the rocks of different districts varied greatly from each other; and often in the same mountain, the upper and lower rocks were observed to be of various kinds and qualities.

In the knowledge of the qualities which ensure durability to the labours of the architect, the ancients appear to have greatly exceeded the moderns; but they did not extend their inquiries respecting rocks to any other objects than those of immediate utility. Nor, till about the middle of the last century, was the structure of the external part of the earth regarded as an object deserving the investigation of men of science, who confined themselves to forming theories of the earth in their studies, in preference to an active examination of nature.

About that time, Lehman, a German mineralogist, observed that certain rocks occupy the lowest relative position in mountainous districts, and that these rocks contain no remains of animals or vegetables; but in the upper rocks, numerous impressions and petrified relics of animals and vegetables abound. Hence he inferred, that the first were consolidated before the existence of organized life; and on this account, they were called primitive or primary. The latter were called secondary rocks, because they not only contained these organic reliques, but also fragments of the former rocks, and hence were supposed to be of later formation.

This division into two classes was continued by geologists until the close of the last century, when M. Werner, the celebrated professor of mineralogy at Freyburg, introduced into his arrangement another class, called transition rocks, which includes those rocks that are, in many of their characters, similar to primary rocks, but in which some organic remains occasionally occur: hence he supposed they were formed when the earth was passing from an uninhabitable to a habitable state. The stratified secondary rocks he denominated *stætz* rocks, from the German word *stætz*, signifying flat, because these rocks are generally divided into parallel strata, which are not greatly inclined from an horizontal position. The lower of these rocks were called the oldest *stætz* rocks, and the upper the newer *stætz* rocks. (See GEOLOGY, where a detailed account is given of the Wernerian arrangement.) Since that article appeared, more extended observations have induced even the warmest supporters of the Wernerian system to question the propriety of some of its distinctions.

"The system of classification introduced by Werner was formed principally from observations made in Saxony, and had great merit, as illustrating the geology of that part of Germany; but it has been objected with much reason to the general adoption of the terms, that they were framed to suit a particular theory, before a sufficient number of facts had been collected to warrant its reception. Subsequent discoveries have also proved, that the different classes, into which Werner has divided rocks, have not the marked and definite characters necessary to constitute a natural system of arrangement. Even the professor who first introduced into this country the divisions of transition and *stætz* rocks, as a most important discovery of Werner, now states his opinion, 'that transition rocks may alternate with *stætz* rocks, and, therefore, that the transition and *stætz* classes are not separated from each other in the manner generally alleged.' This admission is the more remarkable, when we recollect the extreme confidence with which the propriety of this classification

classification was supported, and the solemn trifling often employed to determine whether certain rocks belonged to the transition or flötz classes." (Bakewell's Introduction to Geology, 2d edit.) Indeed the term primary, or primitive, is objected to by some geologists, who consider these rocks as having been in a state of igneous fusion by subterranean fire, which gave to them their crystalline structure; but the heat acted with less force on the rocks by which they are covered, hence the latter are more earthy. Nor are appearances wanting to support this opinion. Well-authenticated instances are known of veins shooting from the lower into the upper rocks; and though much labour has been employed to controvert this fact, it is now undoubted. The granite of Cornwall sends up veins into the superincumbent schistus, or killas; hence it was inferred that the latter, which is considered as a secondary rock, was older than the granite or primary rock. It is evident the killas cannot be of more recent formation. Both rocks were probably contemporaneous; in which case, we may conceive that veins might shoot from the lower into the upper, previously to their acquiring a compact solid state. Nor will the absence of organic remains alone prove the prior formation of these rocks; for among rocks abounding in petrifications of animals or vegetables, many beds of rock occur in which no such remains are ever met with, although we are certain to find them in the strata immediately above and below. We have no means of ascertaining that the similar rocks of different districts were formed at the same time; nor can we be certain that they have not once contained organic remains, that were destroyed during the process by which they acquired their present crystalline structure. We may, however, with apparent probability, infer, that their formation was prior to the existence of animals and vegetables in our planet, in its present state; because the rocks which immediately cover them contain almost exclusively the organic remains of zoophytes, or those animals which are considered as forming the first link in the chain of animated beings.

It is only from the existence of these organic remains, we can infer, with any certainty, that the rocks in which they occur were formed in succession. The difference of these remains in the upper and lower rocks mark distinct epochs in the natural history of the globe. In the lowest rocks, which have a crystalline granitic structure, no animal or vegetable remains have ever been found; but the calcareous rocks, which immediately cover them, contain some few remains of zoophytes and shell-fish; and in the argillaceous slate rocks, also, we occasionally meet with vegetable matter. In the sand-stone strata over these, the remains of vegetables are abundant. Above these again, in the upper calcareous strata, entire fish are occasionally found, with zoophytes and shell-fish, of a species different from those in the lower strata. In the thick beds of aluminous shale and clay over these, occur the remains of the shark and alligator; and in the alluvial soil which covers the whole, the bones of the elephant, the rhinoceros, the hippopotamus, and the mastodonton or mammoth, and of various unknown quadrupeds, are found both in our own country, and in many parts of Europe, Asia, and America. But neither in the upper nor lower rocks, nor in alluvial ground, have any remains of human skeletons been found, except where mines had formerly been worked, or in situations where their occurrence could be explained by recent causes; such as inundations and volcanic operations, as on the shores of Guadaloupe and in the neighbourhood of Vesuvius.

We believe our own countryman, Mr. W. Smith, was the

first person who observed that remains of distinct genera and species of animals were peculiar to certain strata, and that the occurrence of the same remains was sufficient to identify the same stratum, throughout a whole district, wherever it could be examined. The sagacious naturalist M. Cuvier has applied the same discovery to illustrate the geology of the country round Paris, a district most remarkable for the number and variety of fossil skeletons, and other reliquæ which it contains. See STRATA.

It is not a little remarkable, that few of the reliquæ, whether in the upper or lower rocks, belong to existing species of marine or terrestrial animals; and the vegetable petrifications found in northern latitudes resemble most those of tropical climates.

The natural history of rocks comprises, the substances of which they are composed, their internal and external structure, their position, and the order of succession, from the lowest rocks with which we are acquainted upwards to the surface—their decomposition, and the mode of their formation. The latter is the province of speculative geology, for it is only in one class of rocks, the volcanic, that we have any experience of their actual formation.

The mineral repositories peculiar to certain rocks will be described under the article VEINS, *Mineral and Metallic*.

*The Composition of Rocks.*—Rocks are either simple or compound. Those rocks which are composed of one mineral substance, are called simple, such as slate, serpentine, lime-stone, &c. although these minerals may be composed of various elementary substances. Thus clay-slate, or slate, consists of silicæ and alumine, combined with oxyd of iron and carbon; but the combination is so intimate, as to prevent the appearance of an homogeneous substance. When two or more minerals enter into the composition of rocks, they are called compound. Thus granite is composed of quartz, felspar, and mica, closely united together, but each of these minerals preserves its own peculiar character. The elementary substances of which all rocks, both simple and compound, are formed, are, the earths silicæ, alumine, lime, magnesia, the oxyd of iron, carbon, and sulphur. (See SILEX, ALUMINE, &c.) The newly discovered earths and metallic ores, except iron, rarely form the substance of rocks, but are found in the veins and fissures by which they are interjected.

From the above elementary substances, either separately or combined, all the simple minerals are formed which compose rocks and mountains. But it may be remarked, that silicæ enters most largely into the composition of all the lower crystalline rocks (except granular lime-stones): it forms more than two-third parts of the lower crust of the globe.

The most important simple minerals which form rocks and mountains, are quartz, felspar, argillaceous schist, or clay-slate, lime-stone, hornblende, serpentine, chlorite, mica, talc, hornstone, jasper, flint, bituminous shale, and alum-slate. Basaltic or trap rocks, and lava, are sometimes composed of one apparently homogeneous substance, but more frequently they present the appearance of compound rocks. For the characters of these minerals, see QUARTZ, FELSPAR, &c.

When two or more of these minerals are intermixed together, they form compound rocks; in these the minerals are either closely united together, without any visible cement; or aggregated and held together by the intervention of another mineral substance, which serves as a cement, and is sometimes called the paste.

*The Structure of Rocks,* internal and external. The latter, or the structure of rocks *en masse*, is as distinct from the former, as the order of architecture of a building is distinct from

from the form of the bricks or stones of which it is constructed. The internal structure of simple minerals belongs properly to the department of the mineralogist, and that of compound rocks, with their external structure, to the geologist. Compound rocks are either

*Granitic*, composed of grains or crystals, united without a cement, as in granite.

*Porphyritic*, consisting of a compact ground, in which distinct crystals are imbedded; or of a granitic ground, in which some of the crystals are much larger than the rest.

*Amygdaloidal*, from the Latin *amygdala*, an almond, containing kernel-shaped cavities, filled with other mineral substances.

*Conglomerated*, composed of fragments, or rounded stones, cemented together, as in breccias and pudding-stone.

*Granular*, composed of small grains, either cemented, or adhering, as in sand-stones.

The external structure of rocks is either

*Stratified*, composed of layers or strata.

*Tabular*, in large plates: this includes the slaty structure in the mass.

*Columnar*, in regular columns or prisms.

*Globular*, in spherical masses.

*Indeterminate*, which includes all unstratified rocks that have no determinate shape.

Stratified mountains, or rocks, are composed of layers or strata lying over each other, and divided by parallel seams, like the leaves of a closed book. In the seams or partings which divide the strata, there are frequently thin laminae of soft earthy matter, but sometimes the surfaces of the upper and lower stratum are closely joined, and require considerable force to cleave them asunder. The layers are denominated strata. See STRATA.

It has been admitted, without sufficient evidence, that all stratified rocks were formed of the sediment of turbid water, which arranged them in succession over each other, as the muddy waves of the ocean deposit their contents in regular layers upon the shore. This mode of formation is called mechanical deposition. It has also been generally believed, that all rocks divided by parallel seams were formed mechanically by the action of water, and as such layers occur occasionally in crystalline rocks, it was inferred by some geologists that this was a proof that such rocks had been formed by water. Thus the tabular structure, which consists of tables or plates of rock that have generally a vertical direction, and frequently a slaty cleavage, has been confounded with stratification: this has given rise to much confusion and contradiction in the description of rocks; some geologists denying, and others asserting the stratification of the same rock. The tabular and slaty structure of many rocks may, with as great probability, be attributed to crystalline arrangement, as the lamellar structure of a crystal of sulphur, or a plate of mica. The laws of crystallization have but recently arrested the attention of philosophers, and their researches have been principally confined to their effects in a small scale. The crystallization of mountain masses is equally deserving of notice, as to this cause must we refer both their tabular, columnar, and globular structure.

The columnar structure consists of regular columns or polyhedral prisms, and is almost peculiar to trap or basaltic rocks, and to volcanic rocks: these sometimes form vast ranges of natural columns, as in Iceland, the Lipari islands, the Motta in Sicily, the Giants' Causeway in Ireland, and at Staffa. It was long contended against all probability, that these columns were the effects of accidental rents occasioned by the drying or shrinking in of the mass; but their

regularity, and (in many instances) the convex and concave articulations of the joints, prove that they are effects of crystallization. These columns have been observed by Col. Imrie and others formed in currents of lava, that could be traced to the craters of volcanoes. Transactions of the Wernerian Society, vol. ii. pt. 1.

The globular structure consists of balls, sometimes detached, at other times imbedded in rocks of the same kind. These balls are frequently composed of concentric spherical layers. This structure is not unfrequent in basaltic and granitic rocks. The balls are generally harder than the rocks in which they are imbedded, and frequently retain their shape after the outer rock is decomposed. Instances of this structure occur in the basaltic rock of Staffordshire, called Rowley Rag. (See ROWLEY Rag.) Globular distinct concretions of granite are from one to two or more fathoms in diameter. These concretions are again composed of curved lamellar concretions, and always include a harder central mass. The spaces between the globes are filled with granite possessing less solidity, which decays more readily, and thus leaves the harder central masses heaped on each other, or strewn about. These distinct concretions must not be confounded with rolled masses. Beautiful examples of these concretions occur in the island of Arran, Bohemia, the Hartz, the Fichtelgebirge, and other places.

The indeterminate or amorphous structure appears to be the most common in unstratified rocks; but our confined and partial observations may frequently lead us to conclude, that rocks have no determinate structure, whereas, could we ascertain their arrangement throughout their whole extent, we might perceive that their structure, viewed on a great scale, was as regular as that of many stratified rocks.

The position of rocks, with respect to each other, is an interesting subject of geological inquiry, as it is supposed to determine their relative ages, and to elucidate the mode of their formation. When one rock covers another in such a manner as to appear moulded upon it, having the same elevations and depressions, it is said by the German geologists to lie in a conformable position. In this manner the schistose or slaty rocks frequently cover rocks and mountains of granite. Stratified rocks are also generally conformable to the shape of the lower rocks, except in situations where the strata appear to have been broken by some subsequent convulsion of nature, which has deranged their original position, and occasioned them to abut against each other, or has given the upper strata a contrary inclination to the lower. In this case their position is said to be unconformable. Where masses of unstratified rocks cover other rocks, filling up the cavities, and lie without any conformity to the shape of the lower rocks, they are called unconformable and overlying. This position is common to most rocks of volcanic origin, and to basaltic rocks; in the former there can be no doubt respecting the mode of their formation. Streams of liquid lava pouring through vast fissures and openings have covered the inequalities of the lower grounds, filling up vallies, and accumulating as the lava cooled and consolidated, thus forming immense mounds and abrupt precipices: some geologists ascribe a similar formation to basaltic and porphyritic overlying rocks.

Those rocks which are commonly imbedded in other rocks, are said to be subordinate formations; thus granular lime-stone, serpentine, and hornblende, frequently form beds in schistose rocks, such as gneiss, mica-slate, and clay-slate, and are then described by geologists as subordinate to the latter.

Beside the above positions, the continuity of rocks is frequently broken by vertical seams or fissures filled with mineral matter different from that of the rock which they intersect.

(See *VEINS, Mineral and Metallic.*) These vertical seams of rock are sometimes of vast extent, and vary in width from a few inches to several hundred feet. The most obvious inference is, that the solid covering of the globe has been rent, and the mineral matter ejected in a state of fusion into the interstices. The similarity of the mineral matter in the greater part of these fissures, provincially called dykes, to that of volcanic eruptions, adds much probability to this opinion. Where these dykes occur, the original position of the rocks on each side is generally changed.

The dislocation of rocks and strata has been most noticed in mining districts, where it is not unfrequently observed, that a stratum which has extended with a regular inclination over a large track of country, is suddenly thrown down several hundred yards or more, and often sunk below the power of the miner to regain it. Sometimes the strata are thrown upwards, and a series of rocks, which exist on one side of the fracture, are entirely removed on the other, and have totally disappeared.

The change in the original position of all rocks and strata, with respect to the level of the sea, is a most important and incontrovertible fact. Whether the sea has diminished or retired into cavities in the earth, or whether the rocks and mountains have been raised by an expansive force, which has broken the solid covering of our planet, and lifted them from the watery abyss to the present elevation, are questions that may long divide the opinions of geologists; but that the summits of our highest mountains were buried for ages under the ocean cannot admit of doubt. On some of these summits, remains of marine animals are at present widely spread; indeed, many of the calcareous mountains of vast extent and height appear to be almost entirely formed of marine shells, which are not heaped together in confusion, but the upper and lower beds of rock contain remains of species distinct from each other; this proves that they were not deposited in their present situation by any sudden inundation, but have been collected in succession at distant periods of time.

In schistose mountains, considered as primary, the beds of rock have generally a vertical position. Some geologists suppose that all these beds were originally deposited horizontally, and have been subsequently elevated by some mighty convulsion of nature. Saussure, who has investigated with so much labour the structure of the Alps, has drawn this conclusion with respect to the rocks which compose Mont Blanc, and the mountains in its vicinity; but we are inclined to believe that the structure of these mountains, as described by this intelligent philosopher, may in many instances be explained in a more satisfactory manner, by considering it as the result of crystallization on a large scale, and the vertical beds of rock as plates of enormous crystals: indeed, Saussure himself appears to have been very frequently impressed with surprise at the tendency to crystalline arrangement observable in these mountain masses, which he describes as presenting regular pyramidal or rhomboidal forms. The crystalline nature of the rocks themselves, and the minerals which fill the vertical seams, point to crystallization as the great agent in the formation of these mountains, whether it took place in an aqueous solution, or when the whole was in a state of igneous fusion deep under the surface. In one situation near the great pyramids of granite, on the south-east side of the valley of Chamouni, he describes a chain of mountains seven or eight leagues in extent, in which the vertical section of the beds presents an arrangement exactly similar to that of the sticks of an opened fan. The lowest beds are nearly hori-

zontal, but they gradually rise till they become vertical at the summit. He says, that many other instances might be cited of a similar arrangement. Now, we can scarcely conceive it possible for any overturning of the mountain to have produced such a position of the beds; but in the crystallization of minerals on a smaller scale the diverging structure is common. There is, however, one fact, which, if it can be satisfactorily ascertained, will prove the truth of Saussure's opinion, that the vertical position of some of these rocks was not their original one. In his description of the rocks in Valorsine, he says, that he found vast beds of pudding-stone in a vertical position, between schistose rocks in a similar position; the beds on one side are gneiss or mica-slate, and on the other slate and sand-stone. The bed of pudding-stone is 100 toises thick; it consists of a fine paste or cement, composed of extremely fine schistose sand-stone, with minute plates of mica, that are perfectly parallel to the seams which divide the beds.

The fragments vary in size, from that of a grain of sand, to six or seven inches in diameter; some are angular and others rounded, resembling the boulders on the shores of the lake of Geneva. These fragments and boulders are of gneiss, mica-slate, and quartz, but none are of clay-slate. Saussure has observed, that it is impossible for these rounded boulders to have been originally placed in a vertical situation. If they were formed mechanically by the action of water, like those on the borders of the lake of Geneva, this inference is undeniable; and we must farther admit with Saussure, that the mass of this mountain, which is 1181 toises above the level of the sea, has been overturned by the same revolution which has given a vertical direction to the whole; for all these beds having the same inclination and direction as that of the pudding-stone, we are compelled to grant that their original situation was the same, and that they have suffered the same change from the same cause. The only objection to this inference that can, with any probability, be urged, is, that these rounded stones may not really be water-worn boulders and pebbles, but were formed in the same manner as the bolls of basalt and granite, which are sometimes imbedded in basaltic or granitic rocks, and which are acknowledged to be the result of a tendency to crystalline arrangement.

Saussure, however, was fully convinced that they were real boulders, and his guide, on seeing a number of the same rounded fragments on the summit of a mountain in the vicinity, expressed his surprise at finding, in that elevated situation, the pebbles and boulders he was accustomed to see on the borders of the lake. The boulders, in this situation, were evidently the remains of similar beds of pudding-stone, of which the paste or cement had been decomposed and washed away.

It is observed, that secondary strata always rise towards the primitive mountains in their vicinity, which adds probability to the opinion, that the latter were forced up from great depths, and have raised with them the rocks by which they were originally covered, and which now border the primary. The disciples of Werner, however, contend, that the elevation of secondary strata is occasioned by the inclination of the rocks on which they were originally deposited, and that they have undergone no subsequent change.

*Succession of Rocks.*—There are certain rocks, which commonly occupy the lowest relative position in various parts of the world; the rocks which cover them are frequently arranged in a sequence, which has much similarity in distant districts.

Werner, who formed his system from observations made in

in Saxony, where the order of succession presented considerable regularity, concluded that each principal rock constituted what he called a universal formation, or was originally spread round the globe, and that these formations succeeded in a determinate order, encircling each other like the coats of an onion.

More recent and extended observations do not confirm this conclusion to the full extent to which it was carried by the German geologists. Of the thirteen rocks which he classes as primary, some are entirely unknown in various parts of the world, and one of them, the topaz rock, has hitherto been found only in Saxony. Many of the secondary rocks, which occupy a considerable space in Europe, are no where met with in North or South America. In Asia, we are informed by travellers, that a range of mountains, composed of jasper, extends far more than a thousand miles through the eastern parts of Siberia, including Gore island, between that country and America. A geologist, who resided in Siberia, might be disposed to regard jasper as the principal rock-formation in the world, as it extends over a far greater space than the districts in which Werner laid the foundation of his system; on the contrary, in many parts of Europe, jasper is little known, nor is it even enumerated among the principal rocks of Werner.

Mr. Bakewell, in his "Introduction to Geology," admits only three principal rocks in the class of primary; in which arrangement he is supported by D'Aubuisson, an intelligent disciple of Werner, who, on a recent examination of the mountains in the department of Mont Blanc, found that many of the rocks, heretofore regarded as primary, contain some organic remains; hence he admits of one primary formation only, which includes granite, gneiss, and mica-slate.

Brongnart, a celebrated French mineralogist, has more recently declared his opinion, that it is no longer possible to admit the classifications established by Werner. "At the time when these were formed, they rendered an essential service to geology, and created the science; but new observations must produce correspondent changes in the denominations and system of arrangement." *Journal des Mines*, May 1814. Without adhering to systems, further than they are supported by facts, we consider granite as the lowest rock that is generally met with in alpine districts. Granite is frequently covered by a rock called gneiss, a kind of slaty granite; on this occurs micaceous schist, or mica-slate. For the characters of these rocks, see GRANITE, GNEISS, and MICA-Slate.

These three rocks are frequently observed graduating into each other, and sometimes alternating. The substances which compose them appear to have been in a fluid state, and to have united in various forms and proportions; and certain causes have given to the outer part a schistose or slaty structure. The gneiss and mica-slate are generally moulded over the granite, with the same elevations and depressions. Beds of other rocks, particularly of granular lime-stone, hornblende rock, and serpentine, occur occasionally in these rocks, with beds and veins of metallic ores.

The highest mountains on the continents of Europe and Asia are composed of these rocks. Mont Blanc is 15,680 feet above the level of the sea.

Granite rocks are in some instances immediately covered by slate; and in others, secondary stratified rocks rest upon granite, without the intervention of rocks which usually accompany it. More commonly, mountains of slate, or the coarse kind of slate-rock, called by the Germans grey-wacke and grey-wacke slate, cover the mica-slate and gneiss. Im-

mense beds of lime-stone frequently accompany this kind of slate, in which the remains of marine animals, principally zoophytes, appear, but different from any known existing species. A very thick bed of sand-stone, frequently coloured red by the oxyd of iron, often accompanies the coarse slate. It is called by Werner the old red sand-stone, and is succeeded by beds of lime-stone, in which the organic remains of zoophytes and shell-fish are more abundant: these are the lowest rocks in which metallic veins usually occur. Over this lime-stone we meet with numerous strata of argillaceous and siliceous sand-stones, and soft slate or shale, abounding with impressions of vegetables, impregnated with bituminous and carbonaceous matter, and alternating frequently with beds of coal. These secondary stratified rocks, called by the Germans *flötz rocks*, will be more particularly described under the article STRATA.

Again, over the strata containing coal, or more properly on the boundary of these strata nearest the sea, we meet with calcareous strata containing the remains of marine animals, but different from those found in the lower rocks. These calcareous strata consist of calcareous sand-stone, roe-stone, and chalk. See ROE-Stone, and CHALK.

It is remarkable that chalk, which is extensively spread over the southern counties of England, and the opposite coast of France, and in many of the countries adjoining the Baltic, is unknown in North and South America, and various parts of the world. Over the chalk are found thick beds of clay and sand; and in some parts of Europe there occurs over these a series of strata, containing the remains of fresh-water shells and quadrupeds. See STRATA, in which an account will be given of the fresh-water formation of strata in the vicinity of Paris and the southern parts of England. This appears to be the latest formation of rock that we are acquainted with, except what is taking place in our own times by volcanic fires.

It is worthy of remark, that we meet with no organic remains in the lowest rocks we are acquainted with; that the rocks over these contain a few remains principally of marine animals; that the rocks which immediately cover the marine remains, or the coal series, abound in vegetable impressions and carbonaceous matter; but we rarely meet with animal remains of any kind in these strata, until we approach nearer the sea-shore, when other calcareous strata occur again, containing, almost exclusively, the remains of marine animals, but different from those in the lower rocks. These latter strata consist of calcareous sand-stone, roe-stone, and chalk. See ROE-Stone.

Beside the rocks, in which some order of superposition may frequently be traced, there are other rocks which are thrown over them, apparently by some great convulsion of nature which has broken the surface of the globe, and forced them into their present position, without any regular order of succession. These rocks consist of porphyry, sienite, trap, or basalt. From the nature of these rocks, and the similarity of their position with that of volcanic rocks, many philosophers have attributed the same mode of formation to both, and suppose that the former have been originally currents of lavas formed in remote ages.

Humboldt, who has made more extended observations on volcanoes than any philosopher who has preceded him, says, that in the substances which have been ejected during volcanic eruptions, a gradation may be traced from the more ancient to those of more recent date, and that the latter have always a nearer resemblance to the lavas ejected at the present time. If this observation be correct, it will probably lead to the con-

elusion, that rocks of porphyry, sienite, trap, basalt, and lava, had all a similar mode of formation, as they agree in so many characters of composition and structure. See *VOLCANO, VOLCANIC Products, TRAP, and SIENITE.*

As Mont Blanc in Switzerland is the highest mountain on the continent of Europe or Asia that has been examined by any eminent mineralogist, we shall give a short account of its structure, and the rocks which compose its summit, as described by Saussure, who ascended it in 1786, and who had devoted many years to the study of the rocks in its vicinity. These rocks, situated nearly 2400 fathoms above the sea, are interesting, as being the most elevated that have been observed by naturalists; and the scarcity of rock specimens, brought from great elevations, renders his account the more deserving of notice. A more numerous collection of such specimens from various parts of the globe would throw much light on this department of science.

After having gained the highest point of the mountain, "the first thing which struck me," says Saussure, "in the entire view of the high mountainous summits which I had under my eyes from the summit of Mont Blanc, (the highest of them all,) was the kind of disorder which prevailed in their disposition. When we contemplate the range, of which Mont Blanc forms a part, from less considerable elevations, it appears as if these colossal mountains were situated in a line, and formed a chain; but this appearance vanishes entirely from the bird's-eye view which is here presented. The mountains to the north of Mont Blanc, in Savoy and Switzerland, are indeed united among themselves, so as to form mountain chains, but the primitive mountains do not present this appearance. They are distributed in great masses, or in groups of various strange forms, detached from each other, which appear at least but accidentally united, without any regularity. Thus on the east, the lofty peaks called les Aiguilles de Chamouni, the mountains of Argentiere, of Courtes, and of Taleul, form one triangular group, almost detached from Mont Blanc, and only connected with it at the base by a narrow ridge.

"On the south-east likewise, mount Zuc, La Rogne, and the other primitive mountains to the north of the summit of l'Allée Blanche, form a group nearly triangular, separated from Mont Blanc by the valley of the glacier of Miage, and which is only connected with Mont Blanc by the base of the mountains which close that glacier to the north.

"Mont Blanc itself forms a mass almost isolated, the different parts of which are not in the same line, and have no relation of situation with the other groups.

"On casting my eyes still further, I confirmed the same observation. The primitive mountains of Switzerland and Italy, which I had sufficiently near to be under my eyes, presented only separated masses, or detached groups, without order or regularity. Notwithstanding this irregularity in the forms and distributions of the grand masses, I observed certain important resemblances in the structure of their parts. All that I distinctly saw, appeared composed of plates (*feuilles*), arranged in the same manner nearly from north-east to south-west. I had particular pleasure in observing the same structure in the Aiguille du Midi, which I had formerly endeavoured but in vain to study, being prevented by the inaccessible walls of granite that surround the base. I had a view of the Aiguille du Midi on the second day of my ascent, and never lost sight of it as I proceeded. I assured myself that it is entirely composed of magnificent plates of granite, perpendicular to the horizon, and directed from north-east to south-west. Three of these plates, separated from each other, form the summit,

decreasing gradually in height from the southern face, on the side of the Col du Géant.

"When seen from the base, these plates had the appearance of being bent, like the leaves of an artichoke; but this must be an optical illusion, for all those which I could now see distinctly appeared straight; and if there were any exceptions, they were only local, and of small extent.

"This great phenomenon of the vertical position of the plates can only be explained, by admitting a great overturning of the whole mass, which has lifted them from their original horizontal position.

"Another question, which I wanted anxiously to resolve, was also now answered. These great plates of rock preserved the same nature and quality at the summit as at the base, where I had so frequently examined them. This observation proves a remarkable property in mountains with vertical beds: each bed preserves the same nature from the bottom to the top.

"From this magnificent observatory I could comprise in one view the whole of that great phenomenon—which I had before contemplated but in parts—the elevation of the beds forming the mountains on the side of Mont Blanc. On whichever part I turned my eyes, I saw the secondary chains of mountains, and even the primitive of the second order, raising their beds against Mont Blanc, and the high summits in its vicinity. Such were the mountains on the north of Repesoir, of Passy, of Servoz, and Le Buet; on the south, the Col du Ferret, Great St. Bernard, and those of the chain of Cremont, more remote, and beyond the mountainous chains, whose escarpments turn to Mont Blanc. We saw others, whose escarpments were turned in a contrary direction. These appearances are in perfect accordance with the theory which supposes that the crust of the globe has been broken, and the beds of rock raised from their horizontal position. It follows from hence, that the horizontal distance from the bottom of the valley of Chamouni (if that were once the ancient surface of the globe) should have some correspondence with the height of Mont Blanc; and that this distance is nearly the thickness of the stony crust, which has been broken and elevated; and that, consequently, Mont Blanc, which actually rises about a league above the surface, was in its original position buried two leagues beneath it."

The naked rocks on the summit, which form two kinds of arêtes or crests of a dark colour, are of granite. The felspar in this granite is white, inclining to grey, green, or reddish: when exposed to the flame of the blowpipe, it yields a colourless transparent glass, but full of bubbles. The felspar is sometimes intermixed with a kind of earthy steatite. The quartz in this granite is semi-transparent and whitish, and appears rather unctuous in the fracture. Very minute fragments were rounded by the flame of the blow-pipe: it is, therefore, more fusible than rock-crystal. These granites are also intermixed with green and black hornblende, and with chlorite, which seems to supply the place of mica, as the latter scarcely appears, and only in minute spangles. In some places, these granites graduate into irregularly schistose rocks, composed of quartz and felspar, whose seams are filled with a brown argillaceous and ferruginous earth, that melts into a black glass. The granite on the actual summit is composed, like the above, of quartz, felspar, and hornblende or steatite. Felspar constitutes about three-fourths of the mass: the hornblende and steatite form too small a portion to be estimated, the quartz forming nearly the whole of the remaining fourth part. On the northern summit, besides the above species of granite, he

met with a kind of trap rock, composed of minute crystals of white felspar and hornblende. On the southern summit he also found rocks of petrosilex (hornstone), of a pearl-grey colour. It is deserving notice, that the definition of these granites, as given by Saussure, would, according to the Wernerian system, bring them under the denomination of secondary granites; though surely, if any granite can properly be considered as primary, it is that of Mont Blanc, and the mountains in its immediate vicinity.

The following extract from professor Jameson's Geognosy comprises a short view of the order of succession of rocks, as laid down by the German geologists; with observations on the succession of the rocks of Saxony and Hanover, described in the quaint language peculiar to the school of Freyberg.

"In the primitive class of rocks, we observe several rocks always disposed in conformable and unbroken stratification, and in which the newer and newer strata have always a lower and lower level. Gneiss, mica-slate, and clay-slate, are of this kind. The granite stretches under them uninterruptedly, and sometimes rises through them, or juts up in the form of single caps or great masses; so that the gneiss and other rocks are disposed on its surface, sometimes in a concave, sometimes in a convex direction, sometimes saddle-shaped, and frequently mantle-shaped. It is evident from these relations of the strata, that granite will frequently form the greatest heights on the surface of the globe.

"Porphyry has a very different kind of stratification from the preceding rocks. It occurs sometimes broken, sometimes unbroken. When broken, it presents caps, upfillings, and shield-shaped stratification. When unbroken, it forms widely extended masses: its position is unconformable, and overlying.

"Grey-wacke occurs sometimes in a conformable, sometimes in an unconformable position; also in caps, upfillings, and shield-shaped, and frequently mantle-shaped, strata, surrounding the older mountains.

"The lime-stone and sand-stone formations are usually disposed in a mantle-shape, round the older formation; sometimes they are broken, but more frequently unbroken. They are very common and widely distributed formations.

"Coal, again, shews a very peculiar character: its original extent is not considerable; it even appears interrupted, or broken; but its internal characters shew that its present apparently broken appearance is its original one. It occurs commonly in trough and basin-shaped hollows, and its strata have consequently a concave direction.

"The rocks of the newest flötz-trap formation are distinguished from the older by their unconformable, overlying, and broken stratification. In these respects they nearly agree with porphyry. When the continuity of the formation is broken, it occurs in caps, upfillings, and rarely shield-shaped.

"The description we have now given of the succession and structure of the different classes of rocks, will enable us to investigate the structure of the whole mountain groups. We shall illustrate this by a very short description of two well-known tracks of country, the Hartz, and the Saxon Erzgebirge, or metalliferous mountains.

"*Description of the Hartz.*—An immense mass of granite forms the centre of this country; it rises through the other strata, and is elevated a considerable height above them all, forming the famous mountain—the Brocken. Mantle-shaped strata of clay-slate are wrapped around this central mass. It is worthy of remark, that gneiss and mica-slate, two of the most considerable of the older formations, are

wanting in this country. To the clay-slate succeeds transition lime-stone, then grey-wacke, and grey-wacke slate; and the whole of these are wrapped around the granite in mantle-shaped strata, and invariably with lower and lower outgoings, corresponding to the newer and newer strata. The flötz rocks that immediately succeed the transition surround them in mantle-shaped strata. Immediately on the newest of the transition rocks rests the oldest of the flötz, the old red sand-stone; to this succeeds the other flötz formation, in the following order, according to their relative age:—first flötz lime-stone, first flötz gypsum; second or variegated sand-stone, second or newer flötz gypsum, second flötz lime-stone. These flötz rocks are the links that connect the transition with the alluvial, the next class of rocks. These are found in the lowest situations. We have thus, from granite to the alluvial formation, all the series marked with a diminishing level, in proportion to the newness of the strata.

"*Description of the Saxon Erzgebirge.*—The mine district of the electorate of Saxony has a basis of granite which rises through the super-incumbent rocks in the different places at Altenberg, Johannegeorgenstadt, and Bobrisch, on the road leading from Freyberg to Dresden. The newer formations, viz. gneiss, mica-slate, topaz-rock, and clay-slate, are wrapped around the granite in mantle-shaped strata, and the diminishing levels of the outgoings correspond to the newness of the formations. Over these we meet with other primitive formations that overlie the older formations, and their continuity is partly broken, and partly unbroken; here are porphyry, sienite, newer granite, quartz, and serpentine. Still lower down we meet with transition rocks, of which the lime-stone appears at Kalk-grun and Wildenfels; the amygdaloid at Voghtland; and the grey-wacke and grey-wacke slate near Freyberg. Still lower down, and often covering the preceding formations, we find sand-stone and lime-stone; and in several places, as at Hainchen, Pottechappel near Dresden, and Zwickau, there are depositions of the coal formation. Lastly, the newest flötz-trap formation covers all the others in unconformable, overlying, and very broken stratification."

*Decomposition of Rocks.*—Where rocks rise above the surface, and are exposed to the action of air and moisture, they are liable to decomposition and disintegration. The former consists in the separation of the constituent parts, the latter in the separation of the integrant parts: the one may be compared to the moulding of the stones of which a building is constructed, the other to the disjointing and dislocation of the stones in a found state, when a building is thrown down. Both these processes frequently take place in the same rock.

The disintegration of rocks is sometimes rapidly effected by earthquakes, lightning, and the immediate action of subterranean fires. It is, however, to the more constant operations of moisture and change of temperature, that the destruction of rocks and mountains may be principally attributed; but no well-authenticated observations have yet been made to determine the extent of these effects during a given period of time. It has been vaguely stated, that the height of the Pyrenées is diminishing about one foot in a century; hence it was calculated that a million years would be required to level the rocky boundary which separates France and Spain. It is obvious that a lapse of many centuries would be required to verify such a conclusion; and though the decomposition and disintegration of rocks are, in many situations, sufficiently rapid to be observable during the short period of a single life, yet, in other situations,

rocks present the same unvarying outline for ages, and preserve their angular sharpness, which is either natural, or, in some instances, the effect of art. Thus, the blocks of granite remaining in the quarries at Sienna, in Upper Egypt, have all the impressions of the tools with which they were worked during the latter period of the Roman empire; and the basaltic rocks formed by the extinct volcanoes of Auvergne are so compact, as to present, at this day, the appearance of trickling lava suddenly congealed, though the period of their formation was prior to the record of authentic history. The causes of disintegration are, the vicissitudes of the atmosphere, change of temperature, and the absorption and congelation of water. The sudden dilation or contraction produced by the expansion and congelation of water, is alone sufficient to rend the strongest rocks when it enters their fissures. In Greenland the rocks are said, from this cause, frequently to burst with a noise like thunder. The external causes of decomposition are, principally, water and oxygen. Mineral substances, containing sulphur or metallic matter capable of a higher degree of oxygenation, absorb oxygen from water, or the atmosphere. To this cause the decomposition of stones, containing pyrites, is to be attributed. Calces of iron, moderately oxygenated, are the most general cause of decomposition; they act by absorbing a greater portion of oxygen, by which they gradually swell, and are disunited from the other constituent parts of the stone in whose composition they enter. When least oxygenated, their colour is black, or dark brown; and in some instances, when combined with alumine, or magnesia, greenish-grey; the alumine, as it becomes more oxygenated, turns to a purple-red and orange, and finally a pale yellowish-brown; the magnesia becomes at first blue, then purple and red. Iron, in its metallic state, or, at least, when but slightly oxygenated, also decomposes water; but if exposed to the air, it becomes further oxygenated, and the compound into which it enters gradually withers, as Dr. Higgins observed, in imitating pozzolana. Higgins, on Cements, 124.

Stones, into whose composition calces of iron, highly oxygenated, seem originally to have entered, are said, by Mr. Kirwan, to decompose with great difficulty, of which he instances red jasper; but perhaps the more perfect vitrification of these minerals may be the cause of their durability.

Calcareous rocks are liable to the decomposing effects of water, partly mechanical and partly chemical. Carbonate of lime is insoluble in water, except when aided by carbonic acid; but as this exists more or less in almost all water, it acts slowly upon lime-stones, particularly on those of a loose texture. Potash and soda enter also into the composition of many rocks; and to the existence of potash in felspar, one of the constituents of granite, the decomposition of granite rocks may be generally attributed.

From the combination of some extraneous mineral substance with rocks, remarkably rapid instances of the decomposition of rocks are sometimes known to take place. According to Dolomieu, all the houses of Malta are built of a fine grained lime-stone of a loose and soft texture, but which hardens by exposure to the air. There is a circumstance which hastens its destruction and reduces it to powder, namely, when it is wetted by sea-water; after this it never dries, but is covered by a saline efflorescence, and a crust is formed some tenths of an inch thick, mixed with common salt, nitre, and nitrate of lime. Under this crust the stone moulders to dust, the crust falls off, and other crusts are successively formed, until the whole stone is destroyed. A single drop of sea-water is sufficient to produce the

germ of destruction, which gradually increases and spreads, like a canker, through the whole mass of stone; nor does it stop there, but after some time affects all the neighbouring stones in the wall. The stones most subject to this decay are those that contain most magnesia; those that are finer grained, and of a closer texture, resist it. Notwithstanding the speculations of Dolomieu and Mr. Kirwan on the cause of this uncommon property in the stone of Malta, we conceive that a satisfactory explanation is still wanting.

We have before stated, that water is the principal agent in the gradual destruction of rocks, but sometimes entire mountains are suddenly levelled by subterranean currents, which work their passage through fissures and cavities, and silently prepare the causes of the most alarming catastrophes in alpine districts. In proportion to the elevation and abruptness of rocks, these catastrophes are more frequent and extended. In the cantons of Switzerland numerous instances of this kind are on record, and one, which we shall subsequently notice, occurred in our own times.

The town of Pleurs, about a league from Chavennes, containing about 2200 inhabitants, and numerous splendid palaces, was suddenly buried under a mountain on the 25th of August, 1618.

On the same evening an inhabitant, who entered the town, advised his neighbours to leave the place, saying, he had seen the mountains cleaving, but could obtain no credit; his daughter, whom he had persuaded to depart with him, returned to lock up some valuables, and was overwhelmed with all the other inhabitants in one common ruin. Mr. Coxe says vineyards, chestnut trees, and houses, now cover the spot where this unfortunate town once stood.

On the 23d of September, 1714, a great part of the mountain Diableret fell in between two and three o'clock in the afternoon, and buried more than 100 huts, and a considerable part of the valley. Those who saw this disaster say that it happened in a moment, and at the same time whirling clouds of dust arose suddenly, which darkened the air like a sudden night.

In 1751, a mountain fell down, situated near Pally, between Salanches and Servoz. Saussure says, the noise was so dreadful, and so thick and dark a cloud of dust arose, that many persons supposed that the world was at an end. Intelligence was received at Turin, that a terrible volcano had broken forth in these mountains: in consequence of which the king sent the celebrated naturalist, Vitaliano Donati, to verify the report, who gives the following account of the event. "I hurried with extreme pleasure to examine so extraordinary a phenomenon. After having travelled four days and four nights without halting, I came in front of a mountain all covered with smoke, and from which were incessantly detached, both by day and night, large masses of stone with a noise perfectly like that of thunder, or of a large battery of cannon, but louder and more terrible. The peasants had all retired from the vicinity, and did not dare to look at the ruin, but at the distance of two miles, or even farther. All the neighbouring hills were covered with a dust much resembling ashes. All said they had seen at intervals a smoke, which was red during the day, and accompanied with flames at night. I attentively examined the smoke, but neither perceived flames nor any smell of sulphur. Nor did the rivulets I examined with care, present the least appearance of sulphuric matter. Thus persuaded, I entered the smoke, and though quite alone, went to the brink of the abyss, where I saw a large rock darted down, and observed that the smoke was only dust raised by the fall of the rocks, the cause of which I

soon after fought for and discovered.—A great part of the mountain situated above that which had fallen was composed of earth and stones, not disposed in beds, but confusedly heaped together. I thus perceived that the mountain had been subject to similar falls, which had left the large rock that fell this year without a support, and with a considerable projection. This rock was composed of horizontal beds, of which the lower were of slate, or rather of fragile schistose stone of little consistency, while the two beds beneath these were of marble like that of Porto Venere, but full of fissures, which crossed the beds. The fifth bed was wholly composed of slate in vertical plates, entirely disunited; this bed formed all the upper part of the fallen mountain. Upon the same level summit were three lakes, the waters of which penetrated constantly through the fissures of the beds of rock, and decomposed their supports. The snow, which had fallen in Savoy in greater abundance than had ever been seen in the memory of man, increased the effect, and the united waters occasioned the fall of three million cubic fathoms of rock, a mass sufficient to form a large mountain."

On the 2d of September 1806, at five in the evening, the Knippenhoul rock, which formed the summit of mount Rosenbergh, was on a sudden detached from its situation; and at the same time part of the mountain, about 280 feet thick on the east side, and several feet thick on the west, gave way, and fell into the valley which separates the lake of Zug from that of Lauwertz. One part of the mountain fell into the lake of Lauwertz, which caused such an agitation in the waters of the lake, that they overthrew a number of houses, chapels, mills, &c. along the northern shore. Upwards of 1000 persons were the victims of this calamity. A society of thirteen travellers were on the road from Arth to Schwetz; nine who walked first perished, the other four escaped. In this convulsion enormous pieces of rock were carried through the air to prodigious distances. The lake of Lauwertz has lost about a quarter of its extent. That rich plain, before so beautiful, now presents a mountain of 100 feet in height,  $1\frac{1}{2}$  league in length, and as much in breadth. The villages of Goldau and Rothen, consisting of 115 houses; that of Balingen, of 126; and that of Kuslock, have totally disappeared. Of Lauwertz, which had 25 houses, there remain ten buildings, all much damaged. Twenty years previously, general Pfyffer predicted this catastrophe, from the knowledge he had of the nature of the mountain. A professor of Schwitz said, that above Spietsflu there was a lake of water which had undermined the rock for several years, and that below there was a cavern of great depth, where the waters were ingulphed. The quantity of water which had fallen during the preceding years hastened the catastrophe, and the rains of some preceding weeks decided it. On the 10th, eight hundred persons were employed in digging for the bodies of those who were destroyed by the falling of the mountain. In forming a channel to draw off the waters, between thirty and forty labourers were swallowed up by a torrent of muddy water which broke in upon them suddenly. Annual Register, 1806, page 449.

In the mountainous parts of North Wales, Cumberland, and Westmoreland, similar effects, on a diminutive scale, are taking place; and the scattered masses of rock, spread widely over the sides and feet of the hills, prove that they have once had a greater elevation.

By the decay of rocks and mountains, new and productive soils are formed to renovate the surface of the globe, and fit it for the support of vegetable and animal life; and it has been remarked that those rocks which form the most fer-

tile soils, are precisely those which decompose with the greatest rapidity, whilst those which are unfavourable to vegetation resist, for ages, the effects of atmospheric influence. It can scarcely be denied that this beneficent provision of the Author of nature, is ordained to repair the constant waste and change which are taking place on the surface.

"Nec species sua cuique manet, rerumque novatrix  
Ex aliis alias reparat natura figuras." Ovid.

*The formation of rocks*, or the process by which they acquired their present form and consistence, may, perhaps, ever remain a subject of uncertain speculation, as no analogous formations are now taking place, except in one class of rocks, the volcanic.

Some geologists contend that all the solid materials in the mineral kingdom were once in a state of aqueous solution, from which rocks and strata were formed, partly by chemical precipitation, and partly by sediment; the lower crystalline rocks being entirely chemical products, the intermediate or transition partly chemical and partly mechanical depositions; and the upper rocks and strata principally mechanical, or formed of sediment or the fragments of former rocks. It has been objected to this hypothesis, that neither the elementary substances, nor the compounds of which rocks are formed, are soluble in water. In reply to this it has been contended, that though the substances called elementary are insoluble, in all probability there was a time when they existed in a more simple uncombined state; and that the more simple elements were once soluble in water, though the present substances called elementary are not so; in the same manner as very soluble substances are known to become nearly insoluble by chemical union with each other, of which we have an instance in the tartareous acid and potash, which are both very soluble, but when united in certain proportions, they form a salt that can only be dissolved in twenty times its weight of water.

According to these geologists, the quantity of water which once covered the whole globe must have been much greater than at present; but in what manner it has been diminished they do not attempt to explain.

Other geologists suppose that most of the rocks, whether stratified or not, were formed of the sand, or sediment, washed down from former continents, and that they have acquired their present structure and hardness from the action of a central fire, which they believe to exist constantly in our planet, but which is called into greater activity at certain periods by laws with which we are unacquainted. According to the system of these philosophers, the present continents were raised from the bottom of the ocean by the action of the same fire, and the rocks of basalt and porphyry were forced through, and spread over, the surface in a state of fusion, like currents of lava from active volcanoes. It must be admitted, that the only instances we have of the formation of rocks, in our own times, are from the agency of fire; and that some of the lavas present the crystalline internal structure, or contain imbedded crystals as perfect as those found in primary rocks. It is foreign to the purpose of this article to discuss the probabilities of those two theories which have acquired the names of the Neptunian and Plutonian, for an account of which, see EARTH. The descent of stony masses from the atmosphere, sometimes of great size and weight, is now fully proved; and the formation of these stones, from the concretion of gaseous matter, may probably throw some light ultimately on the most abstruse questions in geology, and lead to new, and more correct, views of the nature of our planet. Perhaps the different primary beds of stone, that environ the globe, were formed by similar concretions from an atmosphere of vast extent. Of one thing

## ROCK.

thing we are certain, that the formation of many of the secondary strata was subsequent to the existence of animal and vegetable life; were it not so, their remains could not be enveloped in them. Another fact is not less certain, that many of these beds were deposited very gradually, and form a medium in a state of perfect tranquillity: this is proved by the extremely delicate unbroken fibres and spines of some of the organic remains which could not have been preserved entire, had the particles of the stony matter, by which they are covered and imbedded, been of considerable size, or had they been deposited in a tumultuous element. See STRATA.

Rocks, beside furnishing the metallic ores, and materials for architecture, have the most important uses in the physical constitution of the globe, not only as forming the solid bases or skeletons on which islands and continents are constructed, but these elevations and inequalities are absolutely necessary to supply the dry land with pure and running streams, and to drain the superfluity of moisture in rainy seasons, which would otherwise form stagnant and putrid pools, infecting the air with death: without these rocky elevations the earth must remain a solitary desert, fitted only for the abode of reptiles and amphibious animals. Thus, by the very irregularity and confusion which seem to prevail in the disposition of the fractured surface of the globe, it is rendered salubrious and productive, and prepared to satisfy the wants, and gratify the various inclinations and instincts, of its numerous inhabitants.

ROCK, in *Agriculture*, a stony substance of different kinds, that frequently affords much interruption to tillage, and is highly injurious as a substratum, that occasionally upholds water, and prevents its passing downwards. Where this last is the case, they are mostly of the close, hard, compact kind. They may likewise be hurtful in other ways, as by covering the surface of grass-land, and by occupying lands which might otherwise produce useful plants. Their effects, as non-conductors of water, depends upon their qualities, in some measure, as well as upon that of the beds of earthy matter in which they are situated, and will be more fully considered in speaking of SPRING-draining. The rocky beds of free-stone, blue-stone, and lime-stone, as well as those of some other sorts, exist in very different states, in different parts of the kingdom; and are, on that account, more or less favourable to the purposes of husbandry, in the ground by which they are covered.

Rocks of particular kinds are not unfrequently instrumental, in their decompositions, in contributing to the formation of land or soil. Those lands or soils which arise, in some degree, from the decomposition of rocks of the sandstone and granite kinds, are for the most part of the thin, poor, hungry description; continuing for very great lengths of time, in many cases, with but very slight coverings of vegetable matter or plants of the grassy sort upon them. But those proceeding, in some measure, from the decomposition and mouldering down of rocks of the lime-stone, chalk, and some other kinds, are in general well and closely beset with plants of the permanent grass kind, and give, when broken up, deep rich earthy beds, for the nourishment and support of different sorts of vegetables as crops.

Where lands are situated immediately upon beds or layers of rocks or stones, they mostly become dry, and suitable for the purposes of vegetation, much sooner than where they are deposited upon an under-soil of a clayey or marly nature. This approach of the rocky strata towards the surface-beds of land or soil, is probably one great cause of the fertility of land in moist or wet climates, such as those

of some parts of this country, as many of the more northern districts, and most parts of Ireland.

The rocks and strata of other kinds, from the decompositions of which land or soils have been formed, as well as those which constitute the more internal parts of the globe itself, have a certain order and arrangement, which is not altogether useless to the inquiring farmer; especially as strata of the rocky nature, which are very different in their kinds, not unfrequently happen to be associated together; and those which are placed directly below the layers of land or soil contain materials, which may, in many cases, be of utility in ameliorating them. But the general view of the nature, composition, and position of rocks, whether of the primary or secondary kind, as well as of other natural strata of a similar description, properly belongs to the general head of *rock*; which see. See also SOIL and SUBSOIL.

ROCK, in *Ornamental Gardening*, a substance or body, which is of much utility in producing effect in the forming and laying out the grounds of country residences. It is suggested by Mr. Loudon, that, though in reality these can neither be created, increased, nor taken away, yet that several operations may be effected with them, which seem of the same nature, and consequently to be of much importance in landscape. They may, it is supposed, be either *shewn, concealed*, or rendered more *characteristic*. They may be shewn with more and better effect, by taking away earth from about them, and forming breaks and abruptnesses in the surface of the ground where they are. This may, it is said, be accomplished in many different ways; but that those methods are to be preferred, which are most effectual in shewing a perpendicular surface, or upright front of rock; as it is not only the grandest manner of seeing them that can be contrived, but, at the same time, the most economical and consistent with the good management of the land; no horizontal surface of any consequence, whether of the wood or pasture kind, being to any material extent destroyed. Rocks appear in this way in a great many situations, in different parts of the country, in the ornamental grounds of residences.

It is also further suggested, that rocks may be shewn by removing of wood, either alone, or in connection with ground. This practice, it is supposed, would often have a fine effect on the sides of hills, mountains, and steepes, as well as upon the banks of rivers and lakes; in the last of which cases, it would frequently be assisted in connection with the removal of water, which can often be effected with ease: as, for instance, when a lake has an outlet, or when the channel of a river has considerable declivity. In all cases where rocks are to be shewn, it is constantly the most preferable to exhibit erect, projecting, or at least nearly perpendicular surfaces; as other kinds never occur in nature, except under the surface of water, or in barren deserts: for although they were originally, or after convulsions of nature, left wholly naked, yet by time and circumstances they have gradually become clothed on their upper surfaces by an earthy matter and vegetable productions.

Rocks may be concealed, it is imagined, either completely, or in a partial manner, and by any one or the whole of the materials which shew them. Complete concealment is, however, it is thought, rarely desirable, except in cases where the rocks are of the barren or disagreeable kind; as in the instance of a perfectly naked surface of rocks, or small naked angular fragments of them staring through ground of uniform or simple surface: in the former of which cases, they should be covered with earth; and in the latter, be blown out of the ground by means of gunpowder,

powder, or dug out of it in other ways, as is frequently the case in forming and laying out ornamented grounds.

But partial concealment may often take place in circumstances of this kind, and is, it is supposed, best effected by wood; and in case the form of the part or parts, which appear, be in the grand style, and the concealment accomplished in a judicious manner, the imagination, which is ever ready to magnify the extent or power of indistinct objects, will, it is supposed, conceive the rest to be much more noble, than if they had been of forms capable of being advantageously disclosed. Partial concealment may likewise sometimes be effected by earth or water, and even by buildings; in all of which, the general principles are the same, it is supposed.

It is stated, that in rendering rocks more characteristic, the first requisite is to attend to their general characters: these may either be grand, terrific, fanciful, or romantic and picturesque. Grandeur here consists, it is supposed, commonly in the breadth of light and shade, or the height of the masses; and may be heightened by increasing these, either by removing small parts of the rock itself, or by clearing away the appertaining matters, which tend to conceal or injure the principal masses. Romantic or terrific rocks may, it is thought, sometimes be improved by concealment or disclosure, but rarely by increasing their character. And those of picturesque beauty may often be operated upon with success, either by giving more breadth, variety, or intricacy to the rocks themselves; or by covering them with vegetation; or planting trees before them, to effect variety or harmony; or bushes and creepers above them, to hang over and produce shade and intricacy. An excess of intricacy is, however, suggested, as dangerous, and as tending more than any other quality to make a rock trifling. Crags are said to be frequently trifling on this account, as well as the rock in different situations. In short, the management of rocks, it is imagined, is yet very little, if at all, understood in this country. In many parts they are indeed seen shewn, but in such a way as that they appear little better than upright masses of red earth. The subject is unquestionably deserving of more attention than it has hitherto met with, from the designers of ornamented grounds.

**Rock-Work**, any sort of work or design, which is formed of the parts or fragments of rocks, or large stones, in gardens or pleasure-grounds.

All works of this nature should be contrived in such a manner, as to harmonize as much as possible with the peculiarities of the situations or places in which they are made. See **ROCK** and **STONE**.

They were formerly much more common, in both these situations, than they are at present.

**Rock Alum**. See **ALUM**.

**Rock-Butter**, in *Mineralogy*, a saline mineral, formed in the fissures of rocks of alum-slate. It occurs both massive and staccatitious, and sometimes pulverulent. It has a greyish-white or a straw-yellow colour, and a sweetish and somewhat acidulous astringent taste, like alum. It is indeed a kind of native alum. The feel is somewhat greasy, from which and its colour it has received its name.

**Rock-Cork**, *Suber Montanum*, a flexible and somewhat elastic mineral, found in mineral veins. It is sometimes massive, and sometimes in laminæ or plates: these have been called rock-leather and rock-slesh. The common colour is a yellowish-grey of various shades: it is sometimes a yellowish-brown and cream-colour. It has a fibrous structure and but little lustre. The fractured surface is delicately uneven. This mineral is opaque, and very soft,

yielding to the nail. It breaks with great difficulty, and cracks when handled: it is so light as to swim on water, and is almost infusible in the flame of the blow-pipe.

The constituent parts, as given by Bergmann, are.

Silex	-	-	-	56.2
Magnesia	-	-	-	26.1
Alumine	-	-	-	2
Lime	-	-	-	13.7
Iron	-	-	-	3
				100

Rock-cork approaches in its nature to albitus, from which it differs principally by the promiscuous arrangement of the fibres.

**Rock-Crystal**, the purest variety of crystallized quartz. (See **QUARTZ**.) This stone is sometimes employed in jewellery, and is differently named, according to the places from whence it is procured, as Bristol stone, Scotch pebbles, &c.

**Rock-Fish**, a common English name for the *gobius marinus*, or sea-gudgeon. See **GObIUS NIGER**.

**Rock Germander**, in *Botany*, a species of *veronica*; which see.

**Rock-Oil**. See **PETROLEUM**.

**Rock-Ouzel**, in *Ornithology*. See **RING OUZEL**, and **AMZEL**.

**Rock-Rose**, in *Botany*. See **CISTUS**.

**Rock-Salt**, in *Mineralogy* and *Geology*, a natural salt, of the same kind as common table salt. This useful mineral forms large beds and masses in many parts of the world, and even composes entire mountains. It occurs in large columnar or in spheroidal concretions, and also crystallized in cubes. Rock-salt is subdivided by Werner into two kinds, foliated and fibrous. The more common colours of foliated rock-salt are, white, grey, reddish-brown, and red; but sometimes it is violet, sky-blue, and green, and is more or less transparent or pellucid: it breaks into cubical fragments, which have a vitreous lustre: the structure is indistinctly foliated. In fibrous rock-salt the fibres are generally small and curved; in other respects it differs little from the former. The taste of both is like that of common salt. The red varieties are coloured by earthy matter and oxyd of iron; the white and transparent are extremely pure, being composed almost entirely of muriatic acid and soda, or, according to Davy, of chlorine and sodium. In the purest kind also, there is scarcely any trace of water of crystallization. According to Henry, pure transparent rock-salt, calcined for half an hour in a low red heat, equal to four or five degrees of Wedgewood's pyrometer, lost absolutely nothing of its weight. It is remarkable, also, that if free from any adventitious moisture, it may be suddenly and strongly heated with scarcely any of that found called decrepitation, which is produced by a similar treatment of all the varieties of manufactured common salt. The specific gravity of the purest specimens of rock-salt is about 2.170, of the less pure about 2.130.

Rock-salt is widely distributed over the globe; it appears principally in the lower secondary strata. It is most frequently accompanied with sulphate of lime or gypsum, and by beds of clay impregnated with salt. Beside the beds of rock-salt which are known, numerous brine-springs in various parts of the world attest the existence of this mineral deep under the surface, as it is evident these springs percolate beds of salt, or strata impregnated with it. Several brine-springs have recently been discovered in the deep coal-mines

of Northumberland and Durham. In the coal-mines near Ashby-de-la-Zouch, in Leicestershire, there are springs of brine 245 yards below the surface; and though these springs are in the centre of the island, they are 140 yards below the level of the sea. How much deeper their source may be, has not been ascertained.

The most obvious hypothesis respecting the formation of rock-salt is, the one which supposes that it was deposited from the sea, or by the desiccation of salt lakes which formerly covered the present continents. Against this it has been objected, that the composition of rock-salt is much more pure than the contents of sea-water, which contains a quantity both of muriate and sulphate of magnesia, sulphate of soda, and of sulphate of lime. Rock-salt is also found at great heights above the present level of the sea. These objections will, in a considerable degree, be invalidated by the consideration that whatever impurities there may be in sea-water, if the process of evaporation go on very slowly the salt will be crystallized nearly pure. Of this we have an instance in the species of salt made at Lymington, in Hampshire, called *salt cat*, which is gradually formed in the course of ten or twelve days, by spontaneous evaporation of the liquor which drains from the common salt. This salt is so pure (though evaporated from the most impure part, the mother water, or residue of sea-water), that 1000 parts contain only 12 of foreign impurities, or little more than one *per cent.* Thus if the desiccation of lakes or basins filled with salt water were very gradual, as it must be, except in the vicinity of subterranean fires, the muriate of soda or rock-salt would be crystallized before the other salts, which being more deliquescent might be separated and washed away. In this manner the sulphate of lime or gypsum, which exists in sea-water, and accompanies rock-salt, may also have been deposited, and being nearly insoluble would remain.

The occurrence of rock-salt deep under the earth, or high above the level of the sea, can scarcely form an objection to its formation from sea-water; for it is admitted by all geologists, and is proved by undoubted facts, that the ocean once covered our present continents. Now by whatever process the dry land was raised above the sea, whether by the elevation of the former, or the depression of the beds of the latter, extensive hollows and closed vallies must have formed lakes of salt water, from which the salt might be deposited by evaporation. Some of these vallies or hollows would occur in elevated situations. With respect to the beds of rock-salt placed under other strata, however difficult it may be to explain the formation of the secondary strata, the existence of organic remains in them prove that each stratum was once the uppermost part of the globe, and the strata by which it is covered were deposited upon it in successive and probably at distant periods. Nor is the difficulty greater with respect to the strata covering rock-salt, than the strata covering coal and beds of coal-shale abounding in vegetable impressions. No organic remains have indeed been discovered in the strata over the rock-salt of Cheshire, but they are commonly met with at greater depths over the rock-salt beds in Poland, and in other parts of Europe. The occurrence of rock-salt at the sides or feet of extensive mountainous chains, may perhaps illustrate its formation, as it is probable these extensive chains once formed the boundaries of inland seas or lakes, when the relative level of the ocean and our continents was very different from the present.

Rock-salt is not mined in any part of our island, except Cheshire, though it was bored through at Droitwich; and it exists, in all probability, in many of the

western counties through which the red sand-rock extends. We have proofs of its existence from the brine-springs at Droitwich, in Worcestershire, at Lemington in Warwickshire, and at Ashby Wolds, in Leicestershire; and also in the counties of Northumberland and Durham, on the eastern side of England. The springs at Droitwich furnish a brine as strong as those of Cheshire. A description of the rock-salt of Cheshire being given as an article of rural economy, we shall proceed to give a short account of the most important repositories of this useful mineral in other parts of the world.

Salt is very abundant in Africa; all the plains and sandy deserts are impregnated with salt, and the greater part of the springs in these deserts are so saline, that it is not possible to drink the water. To the south of Abyssinia, at the feet of the mountains which separate that country from that of the Gallas negroes, salt exists in dry and solid masses. The summit of the mountains which border the desert to the west of Cairo, presents an immense plain covered with a mass of salt. According to Horneman it is spread over so large a track of surface, that no eye can reach its termination in one direction; its breadth extends several miles. To the west of the desert of Sahara are the great salt rocks of Tegaza, on the south-east frontier of the desert of Zuenziga, a little distance from Cape Blanc. They are worked by the Moors. These salt mines furnish the white and coloured salt, which is carried by caravans to Casnah and Tombuctoo, to supply the Negro states; for it does not appear that there are any salt mines in Negro land properly called. The mines of salt spread in that part of Africa which the ancients called Libya, have been well indicated by Herodotus, and it is in this country that he has described buildings constructed of rock-salt, like those in Caramania and Arabia. Other salt mines, according to Park, are found on the southern frontier of the great desert Sahara. Their produce is also sold to the Negroes on the borders of the Niger and the Jolibe. In the kingdom of Tunis, mount Had Delfa is entirely composed of very compact salt of a red and violet colour. The lake des Marques, and the plains near it, also contain much salt. There are mines of rock-salt in the country of Bamba, in the kingdom of Congo. On all the western coast of Africa there are salt lakes and marshes. In the neighbourhood of the Cape of Good Hope, and in Caffraria, rock-salt is less common; but there are salt lakes to the east of the Cape, on the frontiers of Caffraria, which contain at the bottom beds of salt variously coloured.

Salt lakes exist in the Cape Verde islands, and natural salt-marshes, particularly in Bona Vista.

Spain is the only country in the south of Europe which contains extensive repositories of rock-salt in considerable masses above the surface. It is found there in elevated situations, forming entire hills: brine-springs also issue from the feet of the mountains which traverse that country. According to the description of Mr. Bowles, the repository of rock-salt which lies between Caparoso and the river Ebro, is in a chain of hills which extend from east to west. These hills are composed of lime-stone, mingled with gypsum, the chain extending more than two leagues. In the most elevated part is situated the village of Valtierra, on a slope towards the middle of which is found a bed of rock-salt. It may be about 400 paces long, and 80 wide. The salt is contained in a bed of about five feet in thickness.

"I examined," he adds, "with attention those beds of salt; I compared them with the layers of earth and gypsum in which it is imbedded; I found the outside layer to be composed of gypsum; and, immediately afterwards, I met with

two inches of white salt, succeeded by two inches of stony salt, and a layer of earth. I found others alternately composed of earth and salt to the very bottom of the mine, which is of gypsum, undulated like the other layers. The layers of saline rock are of a dusky blue, those of salt are white.

"This mine is considerably elevated above the sea, for you ascend continually all the way from Bayonne.

"The second hill is that of Cardona, in Catalonia, near the mountain of Montserrat, sixteen leagues to the N.W. of Barcelona, and a few leagues from the Pyrenees.

"The village of Cardona is situated at the foot of a rock of salt, which, from the sides of the river Cardonere, seems nearly mural. This rock is a block of massive salt, which rises from the earth about four or five hundred feet, without crevices, chafms, or layers. No gypsum is found near it. This block is about a league in circumference; and its elevation is equal to that of the surrounding mountains: as its depth is not known, it is impossible to say on what it rests.

"In general, the salt, from the top to the bottom, is white, though some parts are red; some is also found of a fine blue. There are also in Spain other repositories of rock-salt and saline springs. In La Mancha, at Almengranilla, there is a mass of salt similar to that of Cardona; it is seventy yards in diameter, mixed with sulphate of lime, and covered with the same stone, including crystals of red quartz; above which are siliceous pudding-stones, and a stratum of carbonate of lime."

The mines of rock-salt that are wrought at Poza, near Burgos, in Castille, are remarkably situated, being placed in a vast crater. A French traveller, M. Fernandez, found pumice-stones, puzzolana, and other volcanic productions there.

Rock-salt is likewise found near Aranjuez and Ocanna, in the transition hills between Sierra Morena and Madrid.

On the north side of the Pyrenées no beds of rock-salt have been discovered, but numerous brine-springs occur, particularly at Salies: in the department of the Lower Pyrenées the soil is calcareous, and sulphate of lime is found in the neighbourhood of the spring.

There are salt-springs at Salies, to the south of Thoulouse, also at Salins and Montmorat, in the department of the Jura; in the first of these the water contains fifteen *per cent.* of salt.

There are about twenty brine-springs in the department of La Meurthe, which contain, on the average, thirteen *per cent.* of salt. These springs are at no great distance from each other; some are at the foot of the chain of Jura, the others at the foot of the Vosges: the product of these brine-springs supplies Switzerland with salt. There are salt-springs in the department of Mont Blanc, in the midst of the Higher Alps. In the same department, near St. Maurice, there is a salt-rock near the region of perpetual snow, which is probably the highest situation in Europe where this mineral occurs. The rock consists of gypsum, intermixed or impregnated with salt, which is extracted by solution in water; the insoluble part remains porous and light. Various brine-springs also occur in other parts of France.

Though there are numerous brine-springs in the north of Germany, no beds of rock-salt appear on the surface, until we approach the circle of Austria and the neighbouring countries. The range of salt-rocks commences at Halle, in the Tyrol, passes through Reichenthal in Bavaria, and continues to Hallein in Salzburg, Hallstadt, Ischel, and Ebenfeld, in Austria, and terminates at Aulse in Styria.

The salt at Halle is worked in a peculiar manner: parallel galleries are run into the rock, in these dykes are formed, and water is let into them, where it remains from five to twelve months. When the water is saturated, it is drawn off in pipes, and the solution is evaporated.

On comparing the geological situation of the greater part of the beds of rock-salt and brine-springs, it will be seen that they occur most frequently at the foot of high mountainous chains. The mines of rock-salt in Transylvania, Upper Hungary, Moldavia, and Poland, may be cited in further proof of this. These mines are numerous, and very important from their extent, and the vast masses of salt they contain. They are found along the chain of the Carpathian mountains, and spread nearly in an equal degree on each side of the chain accompanying these mountains to the extent of more than two hundred leagues, from Wieliczka in Poland, towards the north, to Fokizian or Rymnick in Moldavia, to the south.

The strip of land that contains the salt-rock or brine-springs, is near forty leagues broad in some parts. In it may be reckoned about sixteen mines, that are worked for salt; forty-three indications of mines that have never been wrought; and four hundred and twenty, or four hundred and thirty, brine-springs.

The most remarkable of these commence in the north-east, and extend in a southerly direction, including those of Wieliczka, Bochnia, and Samber, in Poland; and some brine-springs in Buchovina and Moldavia, particularly near Ockna. On the south-west of the chain, following the same direction, are those of Sowa, near Eperies, in Upper Hungary; of Marmarosch, in Hungary; of Dees, Torda, Paraid, and Visackna, near Hermanstadt, in Transylvania, &c.

The salt-mines of Wieliczka, near Cracow, and those of Bothnia, which appear to be a branch of them, have become celebrated from the accounts given of them by almost every traveller who has visited that country; many of their descriptions are too highly coloured. They are, indeed, very ancient, having been worked ever since the year 1251; but have nothing to distinguish them above others, except the extent of the works in the beds of rock-salt, the dimensions of which still remain unknown. The ground that covers the rock-salt is composed, like that over most other salt-mines, of alternate strata of sand, pebbles, and marle, including large blocks of salt. You go down to these mines by six shafts, of four or five yards in diameter. Various structures have been formed in the body of the salt itself. We find there a stable, chambers, and chapels, all the parts of which, as pillars, altars, and statues, are of salt. The shafts and galleries are perfectly dry, so that you are more incommoded by dust than dirt. There are springs, however, both of salt water and of fresh in these mines. It appears that the air is not so foul in them as in most salt mines; but the workmen do not reside in them, as some have asserted. In certain parts of the mine, hydrogen gas sometimes collects and explodes.

The salt is cut out in little ascending steps. It is formed into parallelepipedons, weighing about eighty or a hundred pounds, or into cylinders, which are put into casks. This mine produces about six thousand tons of salt every year.

According to the description of Dr. Townson, the salt in the upper mines does not form continuous strata, or rocks, but exists in immense detached blocks or masses, imbedded in marle. He gives the following account of the strata which cover the salt.

	Yards.
Vegetable soil - - - - -	4
Sandy clay - - - - -	10
Fine sand effervescing with acids - - -	7
Marle with sand, containing fragments of sand-stone	18
Sand-stone - - - - -	2
Marle mixed with falt, in small particles and cubes	40

At the depth of forty yards in this marle the falt is found. The blocks of this mineral are of such a size, that in passing through the galleries formed in them, sometimes the upper, and sometimes the lower end only of a block may be seen; but often, though the galleries are three or four yards high, the breadth can only be observed, and even in some places the blocks of falt form the sides of the gallery for fifteen or twenty yards. These blocks compose the upper bed of falt, and from them the whole of what is called the green falt is obtained. This falt, which is of a greenish or blackish hue, owes its colour to numerous fine particles of a substance which seems to be of the nature of argillaceous schist scattered through it. This variety of falt, on account of its impurity, is retained in the country for home consumption. In this marle, also, blocks of sand-stone are sometimes found imbedded, and the marle itself is strongly impregnated with falt. Lower down there is another bed of falt, called szybicker falt, which is in some places two or three yards thick; it is of a purer quality than the former, and is exported to foreign countries. This variety of falt-rock is disposed in very extensive beds. The mine has been driven in one place twelve hundred yards, from east to west, and four hundred from north to south; falt being still found there. The utmost extent is yet unknown. The nature of the stratum beneath the szybicker falt has not been ascertained; for the miners, being apprehensive of increasing the quantity of water, have never proceeded to a great depth in this stratum. The greatest depth of the mine is two hundred and forty yards. It does not appear that the remains of organized bodies have been found in great abundance in the strata connected with the falt-rocks now described. None have been observed, according to Dr. Townson's information, in the szybicker falt, or the lower strata; but some have been seen in the marle which envelopes the block of green falt; such as bivalve shells, at the depth of seventy-two yards; crabs' claws, at the depth of eighty yards; and charred coal, mixed with falt and gypsum, at the great depth of two hundred yards.

From the circumstance of mafs being formerly celebrated in these mines two or three times a week, it has been said that the workmen, to the amount of five hundred, live constantly below ground. They do not, however, continue longer than their hours of working. To keep the mines dry, the falt water is drawn up in leathern sacks, and is thrown away; the small quantity of fresh water which they afford is reserved for the use of the horses which are employed in the subterraneous operations. At the time Mr. Townson visited them, twenty-four horses were constantly kept below ground.

In the mine of Bochnia the falt presents itself in a stratum at once, and not in detached pieces. The strata of clay, as well as those of falt, are undulated, and not of an uniform thickness. The falt is sometimes brown, at others reddish, and at others transparent. The different coloured falt is not arranged in parallel layers. The strata dip at an angle of about forty degrees with the horizon. Dr. Townson informs us that very beautiful specimens of fibrous muriate of soda are found in it.

At Thorda the mafs of falt is divided into horizontal

but undulated strata. These strata are about eight or ten inches thick. The lowest are the most undulated.

Near Oekna, in Moldavia, there is a hill of rock-falt, in many parts of which the falt appears exposed to view.

The mines on the south-east of the Carpathian chain appear more numerous, and are dispersed through a greater space of ground than those on the north-east. They are in general very near the surface. Some of those in Transylvania are so to such a degree, that persons are appointed to cover the falt with turf, when it is washed bare by the rain. These masses, however, are so thick, that their bottom has never been found. They are not worked to the depth of more than a hundred and seventy or eighty yards, because the extraction of the falt becomes then too expensive. In the county of Marmarosch they have been wrought to the depth of upward of two hundred yards. These mines contain likewise a great deal of petroleum, and the ground in which they are contained is every where furrowed by rivers. The mud interposed between the water of these and the falt, is imagined to prevent the falt from being dissolved by them.

At Paraid, in Transylvania, there is a valley, the bottom and sides of which are of pure falt. Walls of falt appear there sixty or seventy yards high.

The mine of Eperies is three hundred and sixty yards deep.

In the falt mines of Marmarosch, water has been found included in the substance of the falt-rock.

The mines of the south-west of the Carpathian mountains are generally wrought by means of shafts. There are at least two to each mine; one for the workmen, the other for drawing up the falt. The falt is cut out in ascending steps, which produces empty spaces, of a conical form, in the midst of the strata. The ladders reach perpendicularly to the bottom of this conical space: so that within it they stand perfectly detached. Thus the greater part of the body of falt is extracted, leaving empty spaces, which are conical, and which communicate with one another by means of galleries. It has been thought, that, in order to leave less falt, it would be better to give these spaces the shape of a parabola. The falt is so plentiful, that the miners are paid only for such pieces as weigh upwards of eighty pounds, the others being rejected as useless. When the workmen are incommoded by water, it is drawn up in leathern bags, to be emptied out of the mine.

The Transylvanians and Moldavians extract falt from their brine-springs, by throwing the water on wood fires, as the Gauls and Germans did in former times.

No falt-mine, or brine-spring, is known either in Sweden, or in Norway.

There are a great number of both, and particularly of falt lakes, in Russia. Among these is the falt lake of Tor, towards the northern extremity of Little Tartary.

There are similar falt lakes in the Crimea.

At Balachna, on the banks of the Wolga, are some very rich brine-springs.

In Rullia, in Asia, we find the brine-springs of Permia, of which there are a great number at the foot of the mountains of Poyas.

About eighty versts from Yena Tayeoska, in the desert between the Wolga and the Uralian mountains, there is a mine of rock-falt.

In the government of Astracan, to the north of the Caspian sea, in the environs of Orenburgh, and in the country of the Bashkirians, falt lakes are very common, and the water evaporating during the summer, the falt appears

appears crystallized on their surface, and round their borders. When this water is highly concentrated, it has a deep red colour. The salt formed in them has often the same hue; and when this is the case, it diffuses a very perceptible violet smell.

One of these is the salt lake of Elton, above Astracan. in the re-entering angle formed by the Wolga. The Kal-mucks called it the Golden lake, because of its red appearance, when the sun shines on it.

The lake of Bogdo, situate near this, yields a perfectly white salt, free from sulphate of magnesia, and preferred to that of lake Elton.

Near Astracan, too, is the mine of Hetzki, celebrated for the quantity of salt it furnishes. The salt lies at no great depth, and rests on a very hard clay. The soil above it is sandy, and full of holes, containing water saturated with salt.

In Siberia there is a mine of rock-salt on the right bank of the Kaptendoi; and on that of the Kawda are fourteen brine-springs. Others are found in the government of Kolvain, and in the environs of Irkutsk, near the lake Baikal, in the centre of Asiatic Russia. Lastly, the country near the Caspian sea is so impregnated with muriate of soda, that in the environs of Gourief, the fogs and dew that settle on people's clothes, and on plants, are saline. Pallas.

Among the Mongul Tartars, the soil is so thoroughly penetrated with muriate of soda, that the people lixiviate it, and evaporate the solution to obtain salt.

That part of China, which borders on Tartary, contains salt-mines, and the ground is strongly impregnated with salt.

Salt is found in the same manner throughout almost the whole table-land of Great Tartary, Thibet, Hindoostan, and particularly Persia, where very extensive plains are seen covered with a saline efflorescence. The isle of Ormus, at the mouth of the Persian gulf, appears, according to the accounts of travellers, to be one large rock of salt. This substance is also found in solid masses near Balach, on the eastern side of Persia. In the desert of Caramania, according to Chardin, rock-salt is so abundant, and the atmosphere so dry, that the inhabitants use it for building their houses. It is found in the neighbourhood of Ispahan, and in the mountains to the north of that city.

The repositories of rock-salt in America are less known. According to Ulloa and others, it is found in vast quantities in the elevated deserts of Peru, at the extraordinary height of 10,000 feet, or more, above the present level of the sea. It is extremely hard, forming solid continuous rocks of a dull violet colour.

The mountain of Xaragua, in the island of St. Domingo, affords salt; and in the same island there is a very remarkable salt lake, about 22 leagues in circumference, called Henriquelle. The water, which is inhabited by lizards, alligators, and land-tortoises, all of a large size, is deep, clear, bitter, salt, and of a disagreeable smell. Near the middle of the lake is an island, about six miles long and three broad, well stocked with goats, whence it has the name of Cabruto island; and in this island is a spring of fresh water.

Salt lakes occur in other of the West India islands. In North America, west of the Alleghany mountains, in the state of Kentucky, are numerous repositories of rock-salt and brine-springs: these are called *licks*, where the elks and buffaloes formerly repaired in herds, to lick the soil impregnated with rock-salt. On the western side of the great river Missouri, a chain of mountains extends 80 miles in length, and 45 in breadth, and of considerable height: it consists of pure rock-salt, barely covered with earth, but

without any tree or shrub. Further west, in California, salt is found in a very pure state, in large and solid masses.

From the preceding account it will be seen that this most useful mineral is found in every quarter of the globe; and in many parts it exists in masses of immense size and extent, compared with the rock-salt in our own island, in the county of Chester. Such, however, is the superior industry of our inhabitants, that the quantity annually exported from that county alone greatly exceeds that procured from any other district in the known world, being not less than 140,000 tons, the produce of the salt-rock and brine-spring; while the celebrated mines at Wieliczka, in Poland, are stated to yield only about 6000 or 7000 tons. Where rock-salt is white or colourless, it is immediately applicable to all useful purposes; but when mixed with earthy matter, it is rendered pure by the simple process of solution in water. The liquor is afterwards drawn off into pans, leaving the insoluble part behind; and the water is then evaporated either by the natural warmth of the climate, or by fires. See SALT.

*Rock-Salt*, in *Rural Economy*, that sort of fossil, rocky, saline material, which is dug out of the bowels of the earth, from different depths, in some parts of this and other countries, where it exists in layers of different thickneses. The beds of this kind of salt, which are found in the county of Chester, are highly interesting and important to the country, whether considered as affording an article of manufacture and commerce, or as forming a source of revenue. The discovery of the beds or strata of this sort of matter, in this district, is, however, of no very remote date, as will be seen under the head of *Rock-Salt Pits*; but the layers are pretty numerous, and of considerable extent, differing greatly in their purity, though, in many instances, requiring a greater or less degree of preparation before the salt can be used.

It is remarked by the writer of the account of the Agriculture of Cheshire, that, from some experiments made on different specimens of rock-salt, it would appear that the transparent kind of it is an almost pure muriate of soda, which contains no admixture of either earth or earthy salts; and that the colour of the less transparent and brown specimens is derived from the earth that enters, in greater or less proportions, into their compositions. That on 480 grains of transparent rock-salt being dissolved in four ounces of distilled water, there was, first, no precipitate let fall, on the addition of carbonate of potash. Secondly, no alteration was produced by this solution on blue vegetable juices. Thirdly, on the addition of a few drops of tincture of galls, a slight purple tinge was given to the solution; and after standing some hours, there was a brown sediment at the bottom of the vessel. Fourthly, on the addition of muriate of barytes, there was no precipitate thrown down. From the first of these trials, it is supposed that rock-salt has no muriate of lime, or muriate of magnesia, combined with it; from the second, that it has no uncombined acid or alkali; from the third, that it contains some portion of iron; and from the fourth, or last, that there is no sulphate of lime contained in it.

And that, on examining different specimens of the less transparent, and the brown rock-salt, with the same reagents as in the above trials, it was found that these consisted of muriate of soda, or sea-salt, in combination with a certain proportion of earth, varying in quantity from one to thirty *per cent.*; also, that the earth was wholly the argillaceous or common clay; but that some of the specimens contained a few grains of sulphate of lime, in 480 of those of the rock-salt.

The beds of this salt are now well known to be the principal

principal cause of the salt-brine springs in this county; and, in connection with some other circumstances, to have a great share in causing the vast differences in their strength, in different places. See *SALT-Brine Springs*.

This is a strong sort of salt, which is found useful for a variety of domestic purposes, according to the different manner in which it is prepared, or the difference in the size of the particles or crystals of which it is composed, as will be more fully shewn under the head *SALT*.

Although rock-salt is found in various parts of the above district, there are no pits of it wrought at present, except in the vicinity of Northwich. And part of the inferior rock-salt, which is procured there, is, it is said, used at some of the refineries in that neighbourhood; and a further quantity sent down the river Weaver, for the supply of the refineries at Frodsham, in the same county, and those on the banks of the Mersey, in Lancashire. The purer rock-salt, or that which is called in general Prussian rock, is carried by the same conveyance to the port of Liverpool; whence, according to the above writer, it is exported chiefly to Ireland, and the ports of the Baltic. The annual quantity of rock-salt sent down the first of the above rivers is found, on the average of the last ten years, to be 51,109 tons. But in this, it is observed, is included what is used at the Frodsham and Lancashire refineries, which may probably be about one-third of the whole. And it is added, that it appears, from the report of the committee of the house of commons, appointed to inquire into the laws respecting the salt duties, printed in June 1801, that,

in 1798	} were exported	} tons of rock-salt.

were sent to different ports in Ireland: the remainder was principally exported to Denmark, Russia, Sweden, Prussia, and Germany. However, a small quantity went to Guernsey, Jersey, and the West Indies.

This shews, in a striking manner, the great utility and advantage of this article in a manufacturing and trading point of view, as well as in other ways.

In regard to the original formation of the beds or strata of rock-salt, in this and other countries, different theories, opinions, and conjectures, have been formed and proposed; but it is one of those geological questions which is extremely embarrassing in its nature, and very difficult in its solution. Mr. Holland has, however, in the above work, ingeniously stated several suppositions on the subject, and the objections to which they are exposed. It is remarked, that wherever rock-salt is met with, sulphate of lime seems to be very generally discovered in mixture with the earthy strata above it. And the writer of the "Memoire sur le Ser Marin," in the 11th volume of the *Annals of Chemistry*, it is added, informs us, that this is the case in Poland, Transylvania, and Hungary; also, that there is commonly a layer of gypsum betwixt the strata of stone and the bed of salt. This gypseous layer is of different colours, and is found crystallized, striated, and mixed with marine shells. The gypsum above the beds of rock-salt in Cheshire is, in like manner, found crystallized and striated; but no marine exuviae, or organic remains, it is observed, are ever met with in any of the strata. Nor does gypsum accompany it, as is usual in other places, as near Cordova, in Spain, where

rock-salt forms a mountain 500 feet in height, and three miles in circumference, as noticed by Kirwan and Townshend. Jars, the author of the "*Voyages Metallurgiques*," who, it is asserted, has given the most particular account we have of the upper stratum of rock-salt about Northwich, remarks, that "it appears to have been deposited by layers or beds of several colours;" and that "these layers of salt are in such a position, as to lead us to believe that the deposition of it was made in waves, similar to those which are formed on the sea-coast."

This, Mr. Holland says, coincides with an opinion suggested by Mr. Stanley, a friend of his, in regard to the probable origin of the beds of rock-salt, now in existence in this district; who states that rock-salt is there found in several strata, one above the other, with intermediate beds of indurated clay, in the vallies of the Weaver, and those of the other rivers and brooks emptying themselves into it; but that it has never been found so near the surface, as to be above the level of the sea, or beneath any solid rock. If beds of rock-salt are to be considered as so many deposits of salt from sea-water, we must suppose the sea, at some former period, to have occupied the vallies in this county; and that, from time to time, the communications were interrupted between these vallies (then deeper than they are now) and the sea. Earthquakes, or accumulations of sand in the estuaries of the Mersey and the Dee, might, it is contended, have caused the interruptions. Whenever the sea-water in the vallies became separated from the sea, the salt contained in it would subside, by the natural process of evaporation. This, it is supposed, would the more easily have taken place, if, by any subterraneous fermentation, the ground below the water should have been heated. To account for a greater accumulation of salt than the sea-water filling all the lowest parts of the district would contain, we must suppose, it is said, that the obstruction interposed between the vallies and the sea had been repeatedly broken down, and renewed again. Tides, unusually high, might occasionally overcome the resistance of the accumulated sand; and if the intervals between the inundations were only of short duration, a subsidence of salt might take place, equal to the formation of the thickest stratum of the rock-salt now existing. Long intervals between the inundations would admit of an accumulation of clay, and other earthy particles, over the salt thus deposited; and in this manner would be formed a new basis for another stratum of rock-salt to repose upon. Thus, it is thought, the regular and astonishing existence of the salt strata may be accounted for, without necessarily supposing them coeval with the original formation of the earth: but to confirm the theory, it is suggested that much observation and close inquiry into the natural history of the county would be required.

Mr. Holland, however, justly thinks that there are many objections to the theory which supposes the beds of rock-salt, in this district, to have been formed by deposition from the waters of the sea; some of which he states rather for the sake of promoting discussion and inquiry, than of affording any very decided opinion on a matter of so much doubt, uncertainty, and obscurity. Though on making a perpendicular section of the upper bed of rock-salt, an irregular stratification, such as noticed by Jars, may, he says, be observed, frequent accurate examination, be observed, the general appearance of the sides of the openings, whence the rock-salt is taken, is that of a confused and irregular red mass; in which some portions of salt have a greater, others a less, proportionate admixture of earth; while, here and there, they may be seen perfectly pure and transparent. He, therefore, asks, is it likely that this irregularity and confusion

tion would have existed, had the beds of rock-salt in this district been formed by the evaporation of sea-water inundating the land at certain intervals of time, as the above theory supposes? On the contrary, says he, would it not be natural to expect from reasonings, *à priori*, that the salt, thus deposited from sea-water, would be disposed in layers perfectly regular, and differing from one another merely in thickness, or a few other circumstances of inferior moment?

Another fact which, it is supposed, invalidates, in some measure, the notion that the rock-salt has been deposited from the waters of the sea, is the great disproportion of quantity, shewn by analysis to exist, between the earthy salts contained in the brine of this district, and those held in solution by sea-water; the ratio here being as one to ten, or the proportion which the earthy salts bear to the pure muriate of soda in sea-water is ten times greater than that which prevails in the Cheshire brine. The ascertaining of this fact proves, it is supposed, that the rock-salt (from the solution of which the brine is formed) is combined with a much smaller proportion of earthy salts than exists in sea-water; a circumstance difficult to be accounted for, on the supposition that the beds of this substance were formed by the evaporation of the sea-water, occupying the vallies and lowest parts of the land. It must be noticed, however, as worthy of attention, that the earthy salts, intermixed with the rock-salt in the above district, are the same which are held in solution by sea-water, being principally muriated magnesia and sulphate of lime.

There is, however, a still stronger proof, it is supposed, against the notion that the beds of rock-salt in this county are depositions from the sea-water, in the circumstance that no marine exuviae have ever been discovered in the strata. This, it is imagined, would almost indubitably have been the case, had the land been covered with sea-water during a period of sufficient length for the deposition of beds of salt of such prodigious thickness; and the fact, that no such exuviae do actually exist, is supposed in itself sufficient to induce a suspicion that the theory in question cannot be well founded. Other objections too, it is observed, offer themselves to its validity; such as the enormous depth of sea-water necessary to the production of a body of rock-salt forty yards in thickness; the difficulty, if not impossibility, on such principles, of accounting for the formation of the singular insulated mountain of rock-salt at Cordova, in Spain; with others of a more trivial nature, which will readily present themselves in this inquiry.

It is, however, at the same time candidly acknowledged, that there are many facts and circumstances of actual observation, that confer a strong degree of plausibility on the opinion, against which it has been contended. The certainty that the surface of the county was at some former period much lower than it is at present, and the diminution of the thickness of the strata of rock-salt in proportion as they recede from the sea, are circumstances which undoubtedly range themselves on this side of the question; and, upon the whole, it is thought, that it may be doubted whether the theory, which regards the beds of rock-salt as deposits from sea-water, does not accord more exactly with existing appearances, than any other which has been adduced on the matter.

It is supposed that many things, which at first seem objections, may be obviated by a reference to the principles of the Huttonian theory of the earth, and the excellent illustrations of it by professor Playfair. However, in the present state of our knowledge, any opinion formed on the

matter must, it is imagined, from its very nature, be purely theoretical. See *Rock-Salt Pits*.

*Rock-Salt Pits*, such pits, shafts, mines, or openings, as are dug or made in any other manner in the ground, for the purpose of getting and raising rock-salt from them. Pits of this sort are met with in many parts of the county of Chester, which are wrought to very considerable extents, and are of great importance to the interests of the district in many different ways, as well as to the nation in general, as may be seen under the head *Rock-Salt*.

According to the statement of Mr. Holland, in his Agricultural Survey of the above county, the first bed and pit of salt-rock was found and wrought in Marbury, at a small distance from the town of Northwich, at the depth of about thirty yards from the surface, in the year 1670, when searching for coal. The bed was thirty yards in thickness, and rested upon a stratum or layer of hard clay. In consequence of this discovery, other similar attempts were made; and on sinking shafts or pits any where in the vicinity of it within the space of half a mile, it was found to exist at about the same depth from the surface of the earth, when not prevented from being dug down to by brine-springs or those of common water. This continued the only place in which it was found until the year 1779, when this sort of rock was again met with in searching for brine in the neighbourhood of Lawton, at the depth of about forty-two yards, but only of the thickness of about four feet; there being beneath it a bed of indurated clay ten yards in thickness, which being penetrated through, a second stratum of rock-salt was discovered twelve feet in thickness; and on continuing the sinking of the pit, another layer of indurated clay, fifteen yards in thickness, was passed through; below which appeared a third stratum of rock-salt, which was sunk into not less than twenty-four yards; the lowest fourteen yards, being the purest, or the least mixed with other substances, were the only parts that were wrought.

Until this period, in the neighbourhood of Northwich, no attempts had, however, been made to sink pits in order to find a lower stratum of rock-salt; as the one which had been first met with was so thick, and furnished such an abundant supply for every demand, there could be no other inducement to this than the expectation of meeting with a stratum, at a greater depth, which might contain a less admixture of earthy matters. It would seem, too, that the fear of meeting with springs below, which might impede the working out of the materials from the pits, and even render this wholly impracticable, prevented the proprietors of them from sinking deeper. As, however, no inconvenience or interruption of this nature had occurred, on sinking through different alternate strata of rock-salt and clay at Lawton; and it had been found that there was a lower stratum of rock-salt there, which was more pure than those nearer the surface, the owners of one of the works or pits in this vicinity were induced, a little time after the trials at Lawton, as in 1781, to sink deeper than had yet been done, and to pass through the bed or body of indurated clay lying underneath the rock-salt, which had been so long known and wrought. This indurated clayey material was found to be from ten to eleven yards in thickness; and immediately beneath it a second stratum of rock-salt was met with, the upper part of which differed little in purity from that of the higher stratum or layer of rock; but on penetrating into it to the extent of from twenty to twenty-five yards, it was there found to be much more pure and free from earthy admixture.

ture. But it continued to have this increased degree of purity for four or five yards only; while, for fourteen yards still lower, to which depth the pit or shaft was sunk, the proportion of earthy matter was again as large as in the upper part of the stratum. It was therefore, on this account, thought useless to sink the pit to any greater depth. Many other proprietors of pits, shafts, or mines, in the same neighbourhood, it is stated, followed the example which had been thus set them; and penetrated through the bed of indurated clay lying beneath the upper stratum of rock-salt. A second stratum of rock-salt was constantly met with below this; and on passing down into it, the same order of disposition as to purity was observed, as in the pit or mine in which it had been first noticed and examined; and the same has been found to prevail in all the pits, shafts, works, and mines, which have since been sunk in the same vicinity.

It is further noticed, that there is great uniformity in the strata which are passed through in sinking pits for rock-salt or brine; and that they very generally consist of clay and sulphate of lime mixed in various proportions; that of the latter somewhat increasing as the pit, shaft, or work approaches the rock or brine. The workmen distinguish the clay by the appellation of *metal*, giving it the name of red, brown, or blue metal, according to its colour; and the sulphate of lime by that of *plaster*. See QUARRY.

The strata formed by these are, in general, close and compact; allowing very little fresh water to pass through them. In some places, however, they are broken and porous: and they admit so much fresh water into the pit or work, that whenever they have been met with, it has been usual to discontinue any attempts to pass through them in sinking the pits. In these places the workmen call the metal *saggy*. It was thought not only impracticable to overcome a water, which vulgar prejudice had magnified into a great stream running under ground; but it was believed, even if the sinking could be continued below this, that the water could not be kept out of the pit, shaft, or work, and that it would either weaken the brine so as to destroy its value, or would find its way into the cavity of any rock, pit, or mine which might be found below it. Later experience, it is said, has proved, that these ideas were not altogether well founded. A few years ago an attempt was made in Witton to pass through this porous stratum, in order to get to the brine. It was met with about twenty-eight yards from the surface; the thickness of it was about thirteen feet; and the quantity of water, which was forced through it into the pit or shaft, was three hundred and sixty gallons a minute. By means of a steam-engine, the sinkers were enabled to pass through this water; to fix a gauge or curb a few yards below it, in a stratum of indurated clay; and thence to bring up a wooden frame, supporting a wall of puddled earth twelve inches thick, by which the access of the fresh water into the pit or shaft was in a great degree prevented, and an opportunity given to pass down to the brine below. A shaft was afterwards sunk through this porous stratum, for the purpose of obtaining rock-salt; which object was, after a short time, defeated, by the influx of brine into the shaft at the surface of the upper stratum of rock-salt; an accident originating in a cause completely distinct from the fresh water in the porous stratum or bed. An exact section of the different strata sunk through in reaching the second bed of rock-salt in the pit at Witton, near Northwich, is given by Mr. Holland in the above report; and all the strata in

the neighbourhood of the last town are supposed to have nearly a similar disposition. The inclination of them in the pit or shaft at the above place was from north-west to south-east; and the dip about one yard in nine. The stratum through which the fresh water flowed is shewn, and the level it found, it is said, was sixteen yards from the surface, which, it is remarked, nearly corresponds with that of the brook below. The line of separation between the lowest stratum of earth, and the first of rock-salt, is very exactly defined; they are perfectly distinct, and do not at all run into each other. It is farther noticed, that in carrying a horizontal tunnel for one hundred yards along the upper stratum of rock-salt, this was found to be irregular and unequal on its surface; the irregularities in a great measure corresponding with those on the surface of the ground above.

The highest bed or body of rock-salt in the pits near Northwich is the thickest in those situated the most to the north-east, gradually declining in thickness towards the south-west, so as to lose one-sixth of it in the course of about a mile. It decreases from about thirty yards in those the farthest to the north-east, to about twenty-five in that the most to the south-west.

A singular appearance is remarked to present itself on making a horizontal section of the stratum of rock-salt in the pits: on the whole of the surface made by such a section, various figures, it is said, may be observed, differing in form and size, some of them being nearly circular, others approaching more to an oval form, while in many an irregular pentagon may be traced. Some of them are not more than two or three feet in diameter; others are ten or twelve feet. The lines which form the boundaries of these figures are white, and from two to five or six inches wide. On examining these appearances, they are found, it is said, to be owing to the rock-salt, in the white lines forming the divisions of the figures, being perfectly pure, and free from earthy admixture. When combined with the salt, having earth in various proportions mixed with it, a general effect is produced, it is said, not very distantly resembling mosaic work. This disposition is uniformly observed, it is said, throughout the whole thickness of the stratum of rock-salt; and that in whatever part of it such a section as the above is made, similar appearances are met with. To what cause it has been owing that the rock-salt has been deposited in this singular manner, it is thought difficult to conceive. The whole stratum of rock-salt may, it is supposed, be compared to a mass of basaltic columns; the lines of separation in each pillar being marked by the pure and transparent white salt. These appearances, it is noticed, afford several grounds for inferences favourable to the theory of the earth mentioned under the head rock-salt, to the illustrator of it. See *Rock-Salt*.

It is likewise further observed, that the division betwixt the lower portion of the upper bed of rock-salt, and the indurated clay or stone beneath it, in pits of this kind, is as exactly defined, as that between the upper portion of it and the earth above. That in passing through this stone small veins of rock-salt are met with, here and there running in it, in various directions; and that wherever there has been any little crevice in it, it is found filled up with rock-salt, to which the clay and oxyd of iron have given a deep red tinge. The thickness of this stratum of stone is said to be uniformly found to be from ten to eleven yards; and the lower part of it is as distinct from the second bed of rock-salt, as its upper part is from the first: also that its termination is equally abrupt or sudden.

part of Chester county, South Carolina, and is one of the largest fishing places in the southern states. It is said that a fisherman, with a hand net, sometimes takes 10 or 12,000 shad in a day.

**Rocky Point**, a cape on the S. coast of Jamaica, S. of Carlisle bay.—Also, a cape on the S. shore of lake Erie.—Also, a cape on the coast of New Albion. N. lat.  $41^{\circ} 8'$ . E. long.  $236^{\circ} 5'$ .—Also, a cape on the S.E. coast of Alafshka, so named by Capt. Cook in 1778. N. lat.  $55^{\circ} 10'$ . E. long.  $198^{\circ} 50'$ .

**Rocky River**, a river of the Indiana territory, which runs into the E. side of Mississippi river, about 70 miles below the mouth of Miffla river.

**Rocky Land**, in *Agriculture*, that sort which is much covered or beset with rocks or stones, either upon the surface or underneath it. Land of this kind is very common, and of considerable extent in many parts of the country, and, of course, often very injurious to the operations of tillage, as well as of planting, and many others. See **CLEARING**, and **RECLAIMING**, *Land*.

**ROCO GRANDE**, in *Geography*, an island on the coast of the Spanish Main, in the West Indies. N. lat.  $11^{\circ} 5'$ . W. long.  $67^{\circ} 39'$ .

**ROCOU**. See **ROUCOU**.

**ROCQUIGNY**, in *Geography*, a town of France, in the department of the Ardennes; 12 miles N. of Rethel.

**ROCROY**, a town of France, and principal place of a district, in the department of the Ardennes. The place contains 2875, and the canton 8077 inhabitants, on a territory of  $237\frac{1}{2}$  kilometres, in 12 communes. N. lat.  $49^{\circ} 55'$ . E. long.  $4^{\circ} 35'$ .

**ROD**, *VIRGA*, *Virge*, a wand, or long slender stick, or staff. See **VERGE**.

**ROD** is also used for a land-measure of  $16\frac{1}{2}$  feet: the same with perch and pole. It is likewise a land measure in Sweden, equal to 8 ells or 16 feet, the Swedish foot being to the English as 40 to 39. See **MEASURE**.

There are also local rods of seven yards and an half, or more. Likewise some of smaller lengths in particular places. See **WEIGHTS** and **MEASURES**.

**ROD**, in *Gauging*. See **GAUGING-Rod**.

**ROD**, in the *Manege*, called in French *gaule*, is a switch, held by the horseman in his right hand, partly to represent a sword, and partly to conduct the horse, and second the effects of the hand and heels.

**ROD**, *Rhineland*. See **RHINELAND**.

**RODA**, in *Geography*, a town of Saxony, in Thuringia; 3 miles N. of Sangerhausen.—Also, a town of Spain, in the province of Aragon; 20 miles S. of Ainsa.—Also, a town of Spain, in Catalonia, on the Tar; 6 miles N.N.E. of Vicque.—Also, a town of Saxony, in the principality of Altenburg; 28 miles W.S.W. of Altenburg.—Also, a river of Germany, which runs into the Mayne, 2 miles below Hanau.—Also, a town of Egypt, on the Nile; 3 miles E. of Ashmunein.

**RODA**, *La*, a town of Spain, in New Castile; 19 miles S. of Alarcon.

**RODABERG**. See **RÆTTVIG**.

**RODACH**, a town of Germany, in the principality of

Coburg; 6 miles W.N.W. of Coburg. N. lat.  $50^{\circ} 21'$ . E. long.  $10^{\circ} 57'$ . The town lies on a river of the same name, which runs into the Itsek, 6 miles S. of Coburg.

**RODAK**, a town of Hindoostan, in the country of Delhi; 50 miles E. of Hissar. N. lat.  $29^{\circ}$ . E. long.  $76^{\circ} 35'$ .

**RODANSEE**, a lake of the Ucker Mark of Brandenburg, S. of Templin.

**RODAS**, a town of South America, in the province of Popayan; 65 miles S. of Santa Fé de Antioquia.

**RODATIO**, unufal shortness of the eye-lashes.

**RODAU**, in *Geography*, a town of Saxony, in the Vogtland; 6 miles W. of Plauen.—Also, a river of Germany, which runs into the Wumme, 2 miles W. of Rotenburg, in the county of Verden.

**RODAUN**, a river of Prussia, which joins the Motlau at Dantzic, near which both together fall into the Vistula.

**RODAW**, a town of Prussia, in the province of Oberland; 14 miles E.N.E. of Marienwerder.

**RODBYE**, a sea-port town of Denmark, in the island of Laaland, with a convenient harbour. The principal article of trade is corn; 10 miles S.E. of Naskov. N. lat.  $54^{\circ} 42'$ . E. long.  $11^{\circ} 24'$ .

**RODDA**, a town of Arabia, in the province of Yemen; 4 miles N.W. of Sana.—Also, a town of Egypt, on the Nile, at the mouth of one of the branches of the canal of Joseph; 115 miles S. of Cairo.

**RODDEN**, a river of England, in the county of Salop, which runs into the Tern, 3 miles W. of Wellington.

**RODDEN Cribs**, in *Agriculture*, a sort of large wicker-work basket, for containing the hay or other fodder in farmyards. It is observed by Mr. Marshall, in his "Rural Economy of the Vale of Gloucester," that these large baskets are made of the top wood of willow pollards, and are an utensil common to this county and to Lincolnshire, though situated on the opposite sides of the island: but they are alike grass-land counties, wherein cattle are fattened on hay. They are about six feet in diameter. The height of the basket-work is two feet and a half; of the flakes, three feet and a half; their heads rising about a foot above the basket. The width between the flakes twelve to fourteen inches. The size, that of large hedge-flakes. The thickness of the rods varies from that of a small hedge-stake, down to a well-sized edder.

And in making these hay-baskets, the flakes are first driven in a ring of the required size firmly into the ground. Some of the larger rods are then wound in at the bottom, in the basket-work manner. Upon these the smaller rods are wound; the middle part of the work requiring the least strength, reserving the largest for the top. In the winding and due binding of those the principal part of the art of withy crib making rests. Some makers warm these thick rods in burning straw: others wind them cold; one man drawing them with a rope, while another beats them at the flake with a wooden beetle, until they acquire a degree of suppleness. They are mostly made by men who go about the country, and who by practice make them very completely; winding in the top rods so firmly and so regularly, that it is difficult to know which has been the last put in.

When in use, the cattle lay their necks between the tops of the flakes. Each being thus kept in its place, the maller cattle are in a degree prevented from running round and driving away the underlings. The closeness of these cribs prevents a waste of hay, either by the wind or by the cattle. On the whole they are useful, simple, cheap, and if well made, will last several years.

**RODEBACK**, in *Geography*, a town of the duchy of Holstein; 10 miles E.N.E. of Braamsted.

**RODELHEIM**, a town of Germany, which gives title to a branch of the house of Solms; 3 miles W. of Francfort on the Maine.

**RODEMACK**, or **RODEMACHERON**, a town of France, in the department of the Moselle; 7 miles N. of Thionville.

**RODEN**, a town of the duchy of Wurzburg; 8 miles S. of Gemunden.—Also, a town of Prussia, in the palatinate of Culm; 4 miles N.W. of Bretchen.

**RODENBERG**, a town of Westphalia, in the county of Schauenburg, annexed to Hesse Cassel; near which is a medicinal spring; 4 miles S. of Hagenburg.

**RODENBURG**. See **ARDENBURG**.

**RODENTHALL**, a town of Saxony, in the circle of Erzgebürg; 6 miles E. of Chemnitz.

**RODEO de Tala**, a town of South America, in the province of Tucuman; 100 miles N. of St. Miguel de Tucuman.

**RODER**, **GROS**, a river of Saxony, which runs into the Schwartz Elster, 2 miles below Elsterwerda.

**RODER**, *Klein*, a river of Saxony, which runs into the Schwartz Elster, near Hertzberg.

**RODERICKE**, a town of Switzerland, in the canton of Berne; 3 miles S. of Aarburg.

**RODERODE**, a town of Germany, in the county of Henneberg; 4 miles E.N.E. of Smalkalden.

**RODERSDORF**, a town of Saxony; 4 miles S.W. of Plauen.

**RODES**, or **RHODEZ**, a town of France, and principal place of a district, in the department of the Aveyron, and capital of that department; before the revolution the see of a bishop, suffragan of Bourges; 32 miles N.N.E. of Alby. The place contains 6233, and the canton 12,168 inhabitants, on a territory of 247½ kilometres, in 33 communes. N. lat. 44° 21'. E. long. 2° 39'.

**RODHEIM**, a town of Germany, in the county of Hanau Munzenberg; 9 miles N. of Francfort on the Maine.

**RODIA**, a town of Naples, in Capitanata, on the coast of the Adriatic; 14 miles W.N.W. of Vieste.

**RODIALOWITZ**, a town of Bohemia, in the circle of Boleflau; 12 miles S.E. of Jung Buntzel.

**RODIGA**, a town of Italy, in the duchy of Mantua; 9 miles N.W. of Mantua.

**RODING**, or **RODEN**, a river of England, in the county of Essex, which runs into the Thames, below Barking.

**RODITZ**, a town of Germany, in the principality of Culmbach; 2 miles W. of Hof.

**RODNEY**, **GEORGE BRYDGES**, in *Biography*, a celebrated naval commander, was the son of Henry Rodney, esq. of Walton on Thames, a naval officer, who commanded the yacht in which king George I., attended by the duke of Chandos, used to embark in going to or coming from Hanover, and who, in consequence, asked leave that his son might be called George Brydges. He was the second son, and born in 1718. At the desire, or by the command, of his royal and noble god-fathers, he entered early into the navy, and in 1742 he was lieutenant in the *Namur*, commanded by admiral Matthews. In November of the same year, he was promoted by the admiral to the command of the *Plymouth*, of sixty guns; on returning home he was removed into the *Sheerness*, a small frigate; and in 1744 he was appointed to the command of the *Ludlow-castle*, of forty-four guns. Captain Rodney was, during the war, very

successful, and attained to a considerable degree of professional eminence. In 1753 he married Miss Compton, daughter of Charles Compton, esq. and sister to Spencer, then earl of Northampton. In 1757 he was engaged, under the command of admirals Hawke and Boscawen, to attempt a descent on the coast of France, near Rochefort: and in 1759 he was advanced rear-admiral of the blue. In this same year he was sent to bombard Havre de Grace, where a large force was collected for the purpose of attempting an invasion of this country: He executed the trust committed to him so completely, that the town itself was several times on fire, and the magazines of stores and ammunition burnt with fury upwards of six hours, notwithstanding the exertions used to extinguish it. Thus had admiral Rodney the happiness of totally frustrating the design of the French court; and so completely did he destroy their preparations, that the fort itself, as a naval arsenal, was no longer, during the war, in a state to annoy Great Britain. In 1761 admiral Rodney was very instrumental in the capture of the islands of St. Pierre, Granada, St. Lucia, and St. Vincent, when the whole Caribbees came into the possession of the English. For his skill and bravery in the war, he was, after the conclusion of it, raised to the dignity of a baronet. In 1768, after an expensive, and to sir George Rodney a ruinous, contest with Mr. Howe, he was elected member of parliament for Northampton. His affairs were now so deranged that he exiled himself to France, the government of which had long since trembled at his name. The French king wished to take advantage of his pecuniary embarrassments, and through the duke de Biron made him the most unbounded offers, if he would quit the English for the French service. In reply to this shameful proposal, he said, "my distresses, sir, it is true, have driven me from the bosom of my country, but no temptation can estrange me from her service. Had this offer been voluntary on your part, I should have deemed it an insult, but I am glad to learn it proceeds from a source that can do no wrong." The duke was so struck with the patriotism of the admiral, that he became attached to him as a friend.

Before sir George Rodney's arrival in England, the French had united with the Americans in a war against this country. Towards the close of the year 1779, the chief command of the Leeward islands was given him; upon which he hoisted his flag on board the *Sandwich*. From this time he was very successful against his majesty's enemies, but our limits do not allow us to particularize all the advantages that resulted from his services during the remainder of the war of which we are speaking. In the first year he had done enough to obtain a vote of thanks from the house of lords; and the freedom of the cities of London and Edinburgh; but his great triumph, and that which must not be passed over, was on the 12th of April 1782, in an engagement in the West Indies with count de Grasse. This battle was fought among the islands of Guadaloupe, Dominique, the Saintes, and Marigalante. As soon as the day broke, admiral Rodney threw out the signal for close action, and every vessel obeyed it most scrupulously. The British line was formed at the distance of one cable's length between each ship. As the ships came up separately, they ranged close alongside their opponents, passing along the enemy for that purpose, giving and receiving, while thus taking their stations, a most dreadful and tremendous fire. The action continued in this manner till noon, when admiral Rodney resolved to carry into execution a manœuvre, which he expected would gain him a complete and decisive victory: for this purpose, in his own ship, the *Formidable*, supported by the *Namur*, the *Duke*, and the *Canada*, he bore down with all the sail set

on the enemy's line, within three ships of the centre, and succeeded in breaking through it in a most masterly style. As soon as he had accomplished this, the other ships of his division followed him, and they all wore round, doubled on the enemy, and thus they placed between two fires those vessels which, by the first part of the manœuvre, they had cut off from the rest of the fleet. As soon as admiral Rodney, and the vessels which followed him, wore, he made the signal for the van to tack, by which means they gained the windward of the French, and completed the disorder and confusion, in which the *breaking of the line* had thrown them. One consequence of the breaking of the line was, that opportunities were given for desperate actions between single ships. The whole loss of the enemy on this occasion amounted to eight ships; one had been sunk, and another blown up after she had been taken, and six ships remained in possession of the conquerors. It was esteemed remarkably fortunate, and glorious for the victors, that de Grasse's ship, the *Ville de Paris*, was the only first rate man-of-war that had ever, at that time, been taken and carried into port by any commander of any nation. And this ship was on the present occasion fought so well, that when it struck there were but three men left alive and unhurt on the upper deck.

The British nation were so sensible of the bravery displayed both by officers and men in this action, and of the importance of it as the only means of preserving the remainder of the West India islands, that they manifested the most excessive joy when intelligence of the victory arrived. It came extremely seasonable in other points of view. Neither by land, nor by sea, except where admiral Rodney had been engaged, had we been able to meet the enemy, on any occasion, with great and decisive advantage; and, in too many instances, we had retired from the contest not in the most honourable manner. As the means of obtaining more favourable terms of peace, this important victory was hailed with joy and exultation; and as admiral Rodney was looked up to as the cause of it, the gratitude of the nation towards him was deeply felt, and expressed in warm and glowing language. It was recollected that the fortune of sir George Rodney had been peculiarly singular, as well as highly glorious in the war. Within little more than two years he had given a severe blow to each of our three powerful continental enemies, the French, Spaniards and Dutch. He had in that time taken an admiral of each nation; added twelve line of battle ships, all taken from the enemy, to the British navy; and destroyed five more. He received the unanimous thanks of both houses of parliament; and his majesty added dignity to the peerage of the realm, by calling the victorious admiral to a seat in the upper house.

It has been observed, that the victory of the 12th of April was gained by putting in practice an entirely new system of naval tactics, the adoption of which formed an era in our naval history, and may be regarded as the cause of the glorious victories, by which the fame of British seamen has been raised to such a pitch of glory; and the maritime power of our enemies in the late war, has not only been crippled, but absolutely annihilated. It has been said, in order to derogate from the honour of the admiral, that, in the instance of the 12th of April, it was the effect of chance, and not effected by the foresight of sir George Rodney. This idea has been satisfactorily exposed and refuted. The only question on the subject is, and into which we shall enter at large under the word *TACTICS, Naval*, whether the honour of the plan is due to admiral Rodney or Mr. Clerk, the author of a treatise on "Naval Tactics."

With the brilliant victory of the 12th of April sir George closed his professional career; to his title was added a pension of 2000*l.* to descend to his heirs. He died in London the 24th of May, 1792. For his important services to the West Indian islands in particular, a temple was built to receive his statue at Spanish Town, Jamaica.

A contemporary of the noble admiral said, that as an officer of nautical abilities, none were his superiors, and but few his equals. He possessed a bold and original genius, which always carried him directly to the object he had in view. As a man, he was benevolent, generous, and friendly. He has been known to be writing his private letters, and dictating to three secretaries at the same time. "In private life he displayed the manners of an accomplished gentleman; and he who, when called by his country, could hurl its thunders against the foes, and lead its navies to almost undeviating victory, was, in peace, the ornament of domestic society, and a pattern of that elegant and polished behaviour, which almost always distinguishes the higher orders among us." Stockdale's edition of Campbell's *Lives of the Admirals*.

*RODNEY, Cape*, a cape of New Zealand, being the N.W. point of the entrance into the river Thames. S. lat. 36° 15'. W. long. 184° 53'.

*RODNEY Point*, the N. point of Norton Sound, on the N.W. coast of North America, so called in honour of admiral Rodney. N. lat. 64° 30'. W. long. 166° 3'.

*RODOE*, a small island near the coast of Norway; four miles E.N.E. of Christianland.

*RODOLDESCO*, a town of Italy, in the department of the Mincio; 10 miles S.E. of Mantua.

*RODOLPH I.*, in *Biography*, emperor of Germany, founder of the imperial house of Austria, born in 1218, was the eldest son of Albert IV., count of Hapsburgh and landgrave of Alsace. He was brought up in the court and camp of the emperor Frederic II., and early distinguished himself by his courage and dexterity in martial exercises. On the death of his father, in 1240, he succeeded to a territory of moderate extent, which he endeavoured to augment by military enterprise. He entertained a band of adventurers of different nations, whom he employed either in defending him from his enemies, or in attempts to aggrandize himself at their expence. In 1245 he married a daughter of Burcard, count of Hohenburgh, with whom he obtained some accession of estates. Some years afterwards he served under Ottocar, king of Bohemia, against the Pagan Prussians. In 1273, as he was encamped before the walls of Basil, with whose bishop he was at enmity, he received the very unexpected intelligence, that he was unanimously elected king of the Romans.

Rodolph, then in his 55th year, willingly accepted the offered elevation, though sensible of the arduous task he was undertaking against the opposition of two unsuccessful candidates. He was crowned at Aix-la-Chapelle, and immediately strengthened himself by marrying two of his daughters to the count palatine of Bavaria, and duke of Saxony. He also took measures for ingratiating himself with the pope, Gregory X., who gave his sanction to the election. Alphonso, one of the unsuccessful candidates, was induced by the pope to renounce his pretensions; but Ottocar, the other, king of Bohemia, refused to acknowledge the new emperor, and manifested the bitterest animosity against him. The king of Bohemia was, at this time, one of the most powerful princes in Europe, and was distinguished by his abilities and military skill. Besides Bohemia and Bavaria, he possessed territories in the north of Germany and Hungary; and had lately acquired Austria, with Carinthia and Carniola.

Carniola. Both parties having prepared for the contest, war broke out between the emperor and the king in 1275, and Rodolph commenced his operations with all the vigour of his character. He first marched against Henry, duke of Lower Bavaria, whom Ottocar had secured in his interest, and soon brought him to change his party. He then penetrated into Austria, and appeared under the walls of Vienna, before Ottocar thought of his danger. This prince, finding himself unable to save the Austrian capital, bent his haughty spirit to sue for peace, which was granted upon the condition of his renouncing his claims upon the Austrian provinces, and consenting to acknowledge the emperor, and do homage for Bohemia and his other fiefs. The Austrian provinces, as fiefs, devolved to the empire, and were taken possession of by the emperor.

The mind of Ottocar was so much irritated by the loss and disgrace he had undergone, that he could not bring himself to a faithful execution of the treaty, and the war was renewed in 1277. A fierce battle ensued, in which Rodolph was beaten to the ground by a Thuringian knight, and brought into great danger; but, on the other hand, Ottocar was killed, and his army entirely defeated. Rodolph was prevented from taking possession of Bohemia by Otho, margrave of Brandenburg, and he entered into an accommodation, by which Wenceslaus was acknowledged king of Bohemia, while he himself was to hold Moravia for five years, and was to retain the Austrian provinces. The securing of these to his family was thenceforth a great object of his policy, in which he encountered many difficulties, but at length he succeeded in settling them upon his two sons, Albert and Rodolph.

In the midst of these transactions, the emperor, thinking it would be for his honour to revive the imperial authority in Italy, after the death of Gregory, during the subsequent short-lived pontificate, sent commissaries into that country to exact homage from several of the towns; but, on the accession of Nicholas III. he found it expedient to confirm to the papal see its possessions in Romagna. He afterwards attempted to restore the authority of the empire in Tuscany; but in this he also failed, and was obliged to content himself with drawing large sums from Lucca and other cities for the confirmation of their privileges. No foreign foe now remaining, Rodolph turned his attention to the restoration of peace and order in Germany; and for this purpose it was necessary to enforce the laws against building private fortresses, which were the retreats of banditti, or the refuge of turbulent nobles, who defied all law and authority. Of these strong-holds he razed seventy in one year, condemning to death many of their owners for their violations of the public peace. He made many progresses through the imperial cities, administering justice and making salutary regulations, so that he obtained the title of "a living law," and deserved to be regarded as a second founder of the German empire. In 1283 he engaged in a war against Philip, count of Savoy, who had appropriated several imperial fiefs in Helvetia; but in an action near Morat he was overpowered by numbers, unhorsed, and obliged, for saving himself, to spring into the lake, where he supported himself by the branch of a tree till rescued by his followers. He was, however, victorious, and brought the count to terms of submission. He was likewise successful against the count of Burgundy, who had transferred his homage from the empire to France; but he failed in an attempt to gain possession of Bern, which had declared itself an independent republic. The troubles of Bohemia, in which the oppressions of the regent Otho had excited revolts, while the minor king, Wenceslaus, was detained as a prisoner, called Rodolph into that country. He

delivered Wenceslaus, whom he married to one of his daughters, and left him at the head of the government, in a state of tranquillity. The final object of this emperor was to secure the imperial crown to his only surviving son, Albert; but the electors were not to be persuaded into this measure, and Rodolph was severely mortified with the disappointment. His strength had already begun to fail, and as he was upon his way to Spire he was obliged to stop at Germersheim, where he died in July 1291, in the seventy-third year of his age, and the nineteenth of his reign.

There is scarcely an excellency of body or mind which the biographers of the house of Austria have not attributed to its founder; and it appears from the history of his actions, that few princes have surpassed him in energy of character, and civil and military talents. In the beginning of his career, he seems to have been little scrupulous in the means of aggrandizement; but, as an emperor, he was in general moderate and equitable. In his sixty-fourth year he married, for his second wife, a princess of Burgundy, only fourteen years of age, but no issue proceeded from this ill-sorted union. By his first marriage he had a numerous offspring, of whom six daughters were all united to powerful families. *Mod. Univ. Hist.*

RODOLPH II., emperor of Germany, son of Maximilian II., was born in 1552. His father procured him the crown of Hungary in 1572, and that of Bohemia in 1575, together with the title of king of the Romans. On the death of Maximilian, in 1576, he succeeded to the imperial throne, being then regarded as a highly accomplished prince, conversant with various branches of knowledge. Unfortunately, his taste and acquirements were so far from qualifying him for the station to which he was elevated, that they diverted his attention from the principal duties of a sovereign. He was attached to mechanical inventions, and spent whole days in the shops of clock-makers, turners, and other artists. Chemistry was also one of his favourite studies, with its usual attendant in that age, alchemy. Having been educated among the Jesuits, his zeal for the Catholic religion rendered him unfriendly to those tolerating principles upon which his father had acted. He had succeeded to the sole possession of the territories of the house of Austria, and finding that the Protestant religion had spread in them to a degree that threatened to subvert the superiority of the Catholic, his first care was to restore the preponderance of the latter. His measures for this purpose occasioned revolts, and a total alienation of the minds of his Protestant subjects. In the other parts of the empire, Rodolph took part against the Protestants, and his interference was a principal cause of the deposition and expulsion of the archbishop and elector of Cologne, who had embraced the Protestant religion, and married. Troubles soon arose in his Hungarian dominions, where sultan Amurath III. made various incursions, in which he overran part of Hungary and Croatia. These were, however, chastised by several defeats given to the Turks by the imperial generals. But Mahomet III., the successor of Amurath, took the important town of Agria, in Upper Hungary, and war was maintained, with various fortune, in that kingdom, till a peace was concluded with sultan Achmet, in 1606. Rodolph took little personal share in these events, being chiefly occupied with his studies; and his Hungarian subjects had contracted such a contempt for his character, that they invited his brother, the archduke Matthias, to undertake the government, and in 1607 elected him for their king. Matthias prepared to take possession of his kingdom, and, marching with an army through Austria, projected to make himself master of that duchy. The timid and pacific Rodolph was persuaded to enter into a treaty with

with his brother, by which he ceded to him Hungary and Austria, and Matthias was solemnly inaugurated as sovereign of those countries.

Soon after, disturbances arose in the empire on account of the disputed succession to the duchies of Juliers and Cleves, with which were associated the causes of dissention between the Catholics and Protestants of Germany. Confederations were formed, and both parties prepared for war. The emperor convoked diets, and diligently exerted himself, in order to prevent extremities. He, however, gave his chief confidence to his cousin the archduke Leopold, who, at length, marched into Bohemia, to awe the Protestants that had been rendered discontented, by attempts to introduce the infernal inquisition into the country, and by violations of their privileges. In this emergency they applied for assistance to Matthias, who entered Bohemia, and obliged Leopold to disband his troops. Not content with this success, he so wrought upon his brother, that Rodolph resigned to him his remaining kingdom of Bohemia, of which Matthias received the crown in 1611. Rodolph was, at that time, in a declining state of health; he died in January 1612, in the sixtieth year of his age, and thirty-sixth of his reign. It is said, that the predictions of the celebrated but superstitious astronomer Tycho Brahe, had rendered him distrustful of all his relations, so that he finally shut himself up in his palace, which he never quitted either for exercise or amusement. Among his various studies was that of astronomy, his attachment to which induced him to invite Tycho Brahe to Prague, where he was patronized till his death; and the same patronage was afterwards given to the more eminent Kepler. The Rodolphine tables, commenced by the former, and completed by the latter, have perpetuated the name of this emperor as a promoter of science. Mod. Univ. Hist. Gen. Biog.

**RODOLPHE**, —, one of the most celebrated professors on the French horn that ever existed. Though he usually played the second horn, he mounted as high as the first ever went. His execution was truly wonderful! and he had found the means of producing sounds with his instrument that were never heard before.

This able musician was equally powerful in composition as in performance. In 1773 he set "Jemona," a serious opera, for the marriage of the compt d'Artois. For the Italian theatre he had previously set, in 1765, the comic opera called "Marriage by Capitulation;" and, in 1767, "The blind Man of Palmyra."

**RODOME**, in *Geography*, a town of France, in the department of the Aude; 9 miles S.W. of Quillan.

**RODON**, a town of Sweden, in Jamptland, on lake Storho; 7 miles N.W. of Osterfund. — Also, a small island on the west side of the gulf of Bothnia. N. lat. 62° 23'. E. long. 17° 23'.

**RODONDA**, a small island at the entrance of the harbour of Rio Janeiro.

**RODONI, CAPE**, a cape on the coast of Albania, in the Adriatic. N. lat. 41° 55'. E. long. 19° 16'.

**RODOPE**, a mountain of Romania; 50 miles S. of Filippopol.

**RODOSTO**, a town of European Turkey, in the province of Romania, on the north coast of the sea of Marmora, where the Armenians have one church, and the Greeks live. The environs are fertile in corn and wine; 53 miles N.E. of Gallipoli.

**RODRIGO**. See *CIVDAD Rodrigo*.

**RODRIGUEZ**. See *DIEGO Ruiz*.

**RODRIGUEZ Key**, a small island on the coast of Florida. N. lat. 25°.

**RODRIGUEZIA**, in *Botany*, a genus so named in the *Flora Peruviana*, p. 105, after Emanuel Rodriguez, a Spanish botanist, apothecary to the king of Spain. *De Theis*.

**RODSEG**, in *Geography*, a town of Iltria; 16 miles N.N.E. of Pedena.

**ROE, Sir THOMAS**, in *Biography*, a distinguished traveller and negociator, was born, in 1580, at Low Layton, in Essex. He was sent at an early age to Magdalen college, in Oxford: after he had left that seminary of learning, he passed some time at one of the inns of court. He was made an esquire of the body to queen Elizabeth, towards the close of her reign; and in 1604 he was knighted by king James. At the instigation of Henry, prince of Wales, he undertook an exploratory voyage to Guiana. Having fitted out a ship and pinnace at his own charge, and that of his friends, he sailed in 1609 for the river Amazons, up which he proceeded to the distance of 300 miles, landing in various places to examine the country. Having spent thirteen months in a laborious survey of this part of the American continent, in search of gold, no doubt, he returned to England in 1611. In 1614 he was sent, at the desire of the East India Company, as ambassador to the Mogul emperor, for the purpose of concluding a treaty of peace and commerce. He arrived at Surat in the autumn of that year, and resided at the Mogul court till the beginning of 1618. His conduct in this station did honour to himself and his country; and he made a great number of curious observations on the court and people, of which we have specimens in Purchas's Pilgrims. On his departure from this country, he visited the court of Sebah Abbas in Persia, with whom he made a treaty, by which the East India Company obliged itself to assist him with a fleet, for the purpose of expelling the Portuguese from Ormus, on condition of being allowed a free trade with Persia. After his return, sir Thomas Roe was elected in 1620 a representative in parliament for Cirencester; and in the following year he was nominated ambassador to the Ottoman Porte, which post he occupied under the sultans Osman, Mustapha, and Amurath IV. He performed, in this capacity, some most important services for his country; and he was, at the same time, very serviceable to the Greek church, by protecting it from the oppressions of the Turkish ministers, and from the intrigues of the Jesuits, and other persons attached to the Papal see. In return for his various services, he was assisted in his collection of manuscripts in the Greek and Oriental languages, which he presented to the Bodleian library; and to his care was entrusted the celebrated Alexandrian manuscript of the Bible, presented to Charles I. by Cyril, patriarch of Constantinople. During his embassy, sir Thomas drew up "A true Relation of what lately happened in Constantinople, concerning the Death of Sultan Osman, and the setting up of Mustapha, his Uncle," &c. This was printed in London in 1622. He also kept minutes of his negotiations at the Porte, which remained in manuscript till 1740, when they were published by the society for promoting learning, under the title of "The Negotiations of sir Thomas Roe, in his Embassy to the Ottoman Porte, from the Year 1621 to 1628 inclusive."

After his return from Constantinople, he was sent, in 1629, to mediate a peace between Poland and Sweden. He was afterwards employed in negotiating a treaty with the king of Denmark at Copenhagen; and he went a second time to that court, and also to those of several German princes; and was present at the congress of Hamburgh, and its removals to Ratibon and Vienna. In 1640 he was a representative in parliament for the university of Oxford, and

and made several speeches upon very important occasions. While a member of parliament, he was sent, in 1641, to the diet at Ratibon, to negotiate for the restoration of the late king of Bohemia's son to the Palatinate; and after his return, the king created him a privy-counsellor, and chancellor of the order of the Garter. The view of the approaching national disturbances was thought to have shortened his life, which was terminated in 1644. He left the character of a very able and upright minister, a true patriot, and accomplished gentleman. Besides the works already referred to, he left in manuscript "A compendious Relation of the Proceedings and Acts of the imperial Dyet, held at Ratibon in 1640 and 1641;" and "A Journal of several Proceedings of the Knights of the Garter." Biog. Brit.

ROE, in *Geography*, a river of Ireland, in the county of Londonderry, which rising in the Cairntogher mountains, flows northward through Newtown Limavaddy into lough Foyle.—Also, the name of a small island in Clew bay, county of Mayo, Ireland.

ROE, *La*, a town of France, in the department of the Mayenne; 7 miles N.W. of Craon.

ROE of a fish is that part which contains the spawn or seed thereof.

That of the male fish is usually distinguished by the name of *soft roe*, or *milt*; that of the female by *hard roe*, or *spawn*.

The soft roe, when squeezed, yields a liquor resembling milk; whence its name *milt*. The French call it expressly *milk, lait*.

M. Petit found 342,144 ovula, or little eggs, in the hard roe of a carp eighteen inches long.

Leuwenhoeek, tom. ii. p. 216, only found 211,629 eggs in a carp, but four times the number in a cod; and, p. 188, he says, that a common cod contains 9,344,000 eggs; and that the eggs of a fish of one year old are as big as those of a fish of twenty-five years old. Mem. Acad. R. Scien. an. 1733, p. 290. See MILT and *Fecundity of Fish*.

ROE is also one of the bealls of chafe.

ROE-Buck, the English name of the *cervus* with ramose, cylindrical, and erect horns. It is the smallest of the deer-kind, and has been called *capreolus* and *caprea*, though without the least resemblance of the goat-kind. See CERVUS *Capreolus* and DEER.

The roe-buck is called a *hind* the first year; *gyrle*, the second; *benuse*, the third; *roe-buck of the first head*, the fourth; and a *fair roe-buck*, the fifth.

The roe-buck is a deer well known in Germany; and seems to have also been formerly found in England, though now the race be extinct.

ROE-Buck *Hunting*. See HUNTING.

ROE-Buck *Island*, in *Geography*, a small island in the gulf of Mexico, near the coast of West Florida. N. lat. 30° 17'. W. long. 88° 44'.—Also, a small island at the east extremity of lake Ontario.

ROE-Stone, in *Mineralogy*, a variety of lime-stone, so called because it is composed of small round globules, supposed to resemble the roes of fishes, imbedded in a calcareous cement. These globules are composed of concentric lamellæ, and are evidently the result of crystallization. They vary in size from a grain of mustard-seed to that of a pea: when they are as large as the latter, it is called *pea-stone*. Roe-stone is one of the secondary lime-stones, which may be considered as belonging to the chalk-formation. It lies under chalk in various parts of England, being separated from it by beds of sand and clay. It is found also in many parts of Europe, but, according to Humboldt, is

not met with in South America. Some of the strata of this stone are extensively used for purposes of architecture: the most distinguished are the Ketten stone in Northamptonshire, the Bath fire-stone in Somersethire, and Portland stone in the island of Portland. Portland stone is of a yellowish-white colour: the more compact varieties, when closely inspected, shew a tendency to crystalline arrangement; it is composed of carbonate of lime, with a small admixture of flint and alumine.

The island of Portland is properly an isthmus, situated in Weymouth bay, in the British Channel. The stone is got in every part of the island, but the quarries at Kington are the most productive. According to Mr. Smeaton, the first stratum in the quarry is a dark coloured reddish earth, about one foot thick. To this succeed six feet of stone of an inferior quality, called *cap*. Immediately under this lies the roe-stone or free-stone, which is ten or twelve feet deep; and beneath this bed there is flint or clay. In some parts, irregular veins of quartz run through the roe-stone. The stratum of stone that is wrought for sale lies nearly parallel with the upper surface of the island; and, in general, the cover of earth and rubbish upon it is thin. Several beds of stone lie continuous one above another, varying in thickness from two to four feet, and sometimes more.

Portland stone was brought into repute in the reign of James I., and was employed in the construction of the banqueting-house at Whitehall. After the great fire in London, this stone was generally used by sir Christopher Wren in the construction of the new public edifices, as St. Paul's cathedral, the monument, and almost every building of note in the metropolis. See STONE for *Architecture*.

The different beds of roe-stone abound in marine organic remains, of which the pear ennerite is perhaps the most remarkable. In the lower beds are found the hippocephaloides, or horse-head muscles, which, according to Mr. Townson, are not casts, but petrifications of the fish itself, and do not represent the interior surface of the shells, from which they are perfectly distinct. This stratum also contains the anomia Spinosa of Linnæus. The spines are extremely delicate, and in some specimens are more than half an inch in length; from which circumstance we may infer, that the calcareous earth of this stratum was deposited in an extremely comminuted state, and in a tranquil element, otherwise it is almost impossible to conceive that these spines could have remained unbroken.

ROEDBACH, in *Geography*, a river of the duchy of Berg, which runs into the Rhine, two miles below Zons.

ROELL, HERMANN-ALEXANDER, in *Biography*, a celebrated Protestant divine, and theological professor, was born in 1653 at Doëlberg, in Westphalia. He received an excellent education in the languages and elementary branches of science. In 1670 he went to the university of Utrecht, where he received lectures from the celebrated Francis Burmann on the scriptures; and on his return to Germany, he studied for some time at Marburg, and after that at Heidelberg. From thence he went to Basil and Zurich; and in 1676 he once more visited the United Provinces, and spent two years at the universities of Utrecht and Leyden. No sooner had he returned to his native country than he received an invitation to become pastor of the Protestant church at Cologne, which he declined, owing to ill health; and he undertook the chaplainship to Elizabeth, abbess of Hervorden, and daughter of Frederic, king of Bohemia; which post he retained till the death of the princefs, in 1680. After this he was appointed preacher to Albertine, princefs of Orange, and widow of William of Nassau; in whose household, and at Deventer, he exercised

the ministry till the year 1686, when he was elected professor of divinity at the university of Franeker. In 1704 he accepted an invitation to fill the divinity chair at the university of Utrecht, a post which he retained with great reputation till his death in 1718, when he was in the 66th year of his age. He was author of many works chiefly on theological topics, among which are "A Commentary upon the Epistle to the Ephesians;" "An Analysis of the Epistle to the Colossians;" "An Analysis and Abridgment of the Prophetical Books of the Old Testament;" "Two philosophical Dissertations on Natural Religion, and one on Innate Ideas."

ROELLA, in *Botany*, so named by Linnæus, in Hort. Cliff. 492, to commemorate William Roëll, professor of anatomy at Amsterdam, who enriched Clifford's garden with many rare plants, the seeds of which he had procured from Africa and Japan. Among those from the Cape of Good Hope, was the first species of the present genus.—Linn. Gen. 88. Schreb. 118. Willd. Sp. Pl. v. 1. 918. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 353. Juss. 165. Lamarek Illustr. t. 123. Gært. t. 31.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Campanacea*, Linn. Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, turbinate, permanent, in five large, deep, lanceolate, acute, toothed segments. *Cor.* of one petal, funnel-shaped, deciduous; tube rather shorter than the calyx; limb somewhat spreading, longer than the calyx, deeply five-cleft. Nectary of five converging scales, in the bottom of the corolla, permanent. *Stam.* Filaments five, awl-shaped, standing on the nectary; anthers awl-shaped, converging, equal in length to the filaments, and on a level with the calyx. *Pist.* Germen inferior, oblong; style thread-shaped, the length of the stamens; stigmas two, oblong, depressed, spreading. *Peric.* Capsule cylindrical, shorter than the calyx, crowned with its enlarged spreading segments, two-celled, bursting at the summit. *Seeds* numerous, angular.

Eff. Ch. Corolla funnel-shaped, closed at the bottom by valves bearing the stamens. Stigma in two segments. Capsule inferior, cylindrical, opening at the summit.

Obs. Linnæus attributes two cells to the capsule; Gærtner only one. Probably one may be occasionally abortive. The essential distinction seems to consist in the capsule having a vertical opening, instead of discharging the seeds by torn lateral orifices, as in *Campanula*, to which genus this is certainly, in other respects, very nearly allied. All the known species are natives of the Cape of Good Hope, being green-house plants in England, and having blue flowers.

1. *R. ciliata*. Ciliated Roella. Linn. Sp. Pl. 241. Hort. Cliff. t. 35. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 378. (*Campanula africana frutescens aculeosa*, flore violaceo; Comm. Hort. v. 2. 77. t. 39.)—Leaves lanceolate, fringed, with a prominent point. Flowers terminal, solitary.—Found in various parts of southern Africa. The Dutch have long cultivated it. Mr. Masson sent seeds to Kew in 1774. The plant is not very common, though much to be admired for the beauty of its flowers, which are produced in succession, throughout most part of the summer; but it is not easily increased, nor long preserved, being impatient of our damp winters. The stem is shrubby, of humble growth, branching in a determinate manner; the branches slender, round, leafy. Leaves copious, alternate, small, of a pale dull green, linear-lanceolate, fringed, each ending in a prominent, awl-shaped, rigid point. Flowers solitary at the ends of the branches, an inch and half, or more, in diameter, their colours well described by Curtis as follows. "The bottom of the flower is white, of a yellowish cast; next succeeds a

circle of deep blue, inclining to black, with a surface highly glazed; the next circle is greyish-blue, resembling satin; the next nearly white, and the outermost, (or limb,) pale purple." Each leaf of the plant is accompanied by an axillary tuft of smaller, obtuse, entire, naked ones.

2. *R. squarrosa*. Trailing Roella. Linn. Suppl. 143. Thunb. Prodr. 38. Willd. n. 2. Ait. n. 2.—Leaves ovate, recurved, toothed, fringed. Flowers terminal, aggregate. Stem herbaceous, diffuse.—Gathered by Thunberg at the Cape, and sent from thence to Kew garden, by Masson, in 1787. It blossoms in June. The branches are more spreading and decumbent, as well as of a less shrubby nature, than the former. The *squarrosa* of Bergius, from whom the younger Linnæus adopted the name, is described as a shrub, with solitary flowers. Ours, besides the terminal tuft, has generally several scattered lateral flowers, on short leafy stalks, or branches, which may explain this apparent disagreement.

3. *R. decurrens*. Decurrent Roella. L'Herit. Sert. 4. t. 6. Willd. n. 3. Ait. n. 3.—Leaves lanceolate, entire, fringed, decurrent. Flowers solitary, terminal.—Sent from the Cape, by Mr. Masson, in 1787. This species is annual, flowering in September. The root is small and tapering. Stem much branched from the very bottom, spreading and partly decumbent, hairy. Leaves ovate-lanceolate, fringed, for the most part entire; strongly decurrent, so as to render the stem winged. Flowers terminal, sessile, pale blue, solitary, except occasionally on the most luxuriant branches.

4. *R. muscosa*. Mossy Roella. Linn. Suppl. 143. Willd. n. 4. Thunb. Prodr. 38.—Leaves ovate, toothed, reflexed, smooth. Flowers terminal, solitary. Stem herbaceous, diffuse.—Gathered at the Cape by Thunberg. A very small annual species.

5. *R. spicata*. Spiked Roella. Linn. Suppl. 143. Willd. n. 5. Thunb. Prodr. 38.—Leaves lanceolate, fringed, nearly entire. Flowers terminal, somewhat spiked. Stem shrubby, erect.—Found by Thunberg at the Cape. We have seen no specimen of this or the last.

Linnæus, in Sp. Pl. 241, has a *R. reticulata*, adopted from Van Royen and Petiver, which appears to be no other than his own *Gorteria ciliaris*; *Cullumia ciliaris* of Brown, in Ait. Hort. Kew. v. 5. 137.

ROEMER, OLAUS, in *Biography*, a Danish astronomer and mathematician, who flourished in the 17th and 18th centuries, was born at Arhusen, in Jutland, in the year 1644. From an elementary school at his native city he was sent to the university of Copenhagen, in 1662, where he distinguished himself by the progress which he made in his academical studies, and particularly in the mathematical sciences, which were the favourite subjects of his pursuit. By diligent study he had, in 1671, become so expert an astronomer, that, being introduced to M. Picard of the Academy of Sciences at Paris, who was sent by Louis XIV. to make astronomical observations in the northern regions, he was selected to accompany him when he returned to France. Here he presented him to the king, who appointed him mathematical preceptor to the dauphin, and settled a pension upon him. Roemer was united with Picard and Cassini in making astronomical observations, and in 1672 he was admitted a member of the Royal Academy of Sciences at Paris. He resided ten years at Paris, and acquired a high reputation by his many discoveries, among which was the very important one by which he ascertained the velocity with which light moves, by means of the eclipses of Jupiter's satellites. (See LIGHT.) This discovery was afterwards confirmed by Dr. Bradley. In 1681 Roemer was recalled to his own country by Christian V. king of Denmark,

who appointed him professor of astronomy, at the university of Copenhagen, and gave him the flattering title of *his own mathematician*, with a considerable salary. He was also employed in reforming the coin; improving the public buildings; regulating the weights and measures; and in surveying and laying out the high roads throughout the kingdom. In 1687 the king directed him to travel through Germany, France, England, and Holland, in order to collect such information, on a variety of points, as might be applied to beneficial purposes in Denmark. Upon his return home in the following year, he was made counsellor of the chancery, and in 1693, assessor of the supreme tribunal of justice.

Christian V. was succeeded by Frederic IV. who appointed Roemer, in 1705, burgomaster of Copenhagen, and in 1706, honoured him with the dignity of counsellor of state. Roemer died in 1710, just as he was about to give the world the result of his observations. These, however, were published under the title of "Basis Astronomiæ," in 1753, by Peter Horrebow, who had been his disciple, and was, at the time, professor of astronomy at Copenhagen. Accounts of Roemer's astronomical observations, and some other of his pieces, will be found in the different volumes of the "Memoires" of the Royal Academy at Paris, particularly vols. i. and x.

**ROENBERG**, in *Geography*, a town of Brandenburg, in the New Mark; 8 miles E. of Zullichau.

**ROENENG**, a long measure in Siam, equal to one league, containing 4204 English yards, or 2½ miles nearly.

**ROENSEL**, in *Geography*, a river of the county of Mark, which runs into the Wipper, about a mile above Wipperfart.

**ROER**, a river of Germany, which rises near Winterburg, and runs into the Rhine at Roerort.—Also, a river of France, which rises S. of Montjoe, in the department to which it gives name, and runs into the Meuse at Ruremond.

**ROER**, one of the three departments of the region of France, called the Reunited country; composed of the duchy of Juliers and a portion of the electorate of Cologne, situated in N. lat. 51°, on the left hand of the Rhine. It contains 6697 kilometres, or 259 square miles, and 516,246 inhabitants. It is divided into 4 circles or districts, 40 cantons, and 993 communes. The districts are Aix-la-Chapelle, including 165,261 inhabitants; Cologne, with 157,215; Crevelt, with 137,605; and Cleves, with 76,206 inhabitants. According to Hassenfratz, this department is 23 French leagues in length and 13 in breadth; and comprehends 4 circles, 40 cantons, and 324,960 inhabitants. Its capital is Aix-la-Chapelle. Its contributions, in the 11th year of the French era, were 4,564,150 fr. and its expences for administration and public instruction were 331,936 fr. 66 cents. Interspersed with heaths and marshes, this territory is, in general, fertile in grain, fruits, and pastures. It has mines of copper, iron, lead, and coal, with cold and hot mineral springs.

**ROERMONT**. See RUREMOND.

**ROERORT**, a town of the duchy of Cleves, at the conflux of the Roer and the Rhine; 15 miles N. of Duffeldorf.

**ROESBACH**, a river of the duchy of Berg, which runs into the Rhine at Duffeldorf.

**ROESCHILD**, **ROSCHILD**, *Roeskild*, or *Roskild*, a town of Denmark, in the island of Zealand, erected into a bishopric in the year 1012. In the year 1150 it was first encompassed with a rampart and ditch, and in 1268 or 1278 it obtained the privileges of a city. It gradually increased to such an extent as to contain 27 large churches and convents within its walls. Some of the churches of the neighbouring villages were included within its circuit, and its streets extended as far as the sea-shore. The kings of Denmark were

formerly elected and crowned in this city, and made it the place of their residence. Its subsequent decay has been owing to frequent fires, to the tyranny of its bishops, and also to the flourishing state of Copenhagen. The reformation contributed also to its decline, as the monks and clergy who spent a great part of their revenues in this place, were obliged to quit the country. At present Roeschild is a mean place, containing about 200 houses; the cathedral, built A. D. 930, where the royal families of Denmark have for many ages been buried; and the ruins of a royal palace. Here are some monuments worthy of attention, particularly four elegant mausolea in alabaster, of late kings and queens. The first king who was buried here was Harold Blaacland, A. D. 980, and the last was Frederic V. furnished the Great, A. D. 1766. The inhabitants support themselves chiefly by agriculture, and the planting of tobacco. In the year 1658, the famous peace of Roeschild, between the Swedes and Danes, was concluded here: 16 miles W. of Copenhagen. N. lat. 55° 39'. E. long. 12° 6'.

**ROESCHULT**, a town of Sweden, in the province of Smaland, said to be the native place of the famous Linnæus.

**ROESENDAEL**, a town of Brabant; 8 miles E. of Berg-op-Zoom.

**ROESSEL**. See ROSSEL.

**ROETTVIK**, or **RAETTVIK**, a mountain of Sweden, which, according to Bergman, is calcareous, and the height of which he estimates at 6000 feet above the sea; observing, as a singularity, that upon this mountain and that of Rodeberg, are found vast blocks of reddish felspar, mingled with quartz and brown mica.

**ROEVAERT**, a river of Brabant, which runs from Breda into the sea.

**ROEULX**, **LA**, a town of France, in the department of Gemappe; 8 miles N.E. of Mons.

**ROEUX**, a town of France, in the department of the straits of Calais; 9 miles E. of Arras.

**ROFANI**, a cape of European Turkey, on the S. coast of Romania. N. lat. 40° 35'. E. long. 24° 14'.

**ROFFENSIS TENTUS**. See TENTUS.

**ROFRANO**, in *Geography*, a town of Naples, in Principato Citra; nine miles N.W. of Policastro.

**ROGA**, a town of Naples, in the province of Otranto; seven miles N. of Otranto.

**ROGA**, *ρογα*, in *Antiquity*, a donative, or present, which the Augusti, or emperors, made to the senators, magistrates, and even the people; and the popes, or patriarchs, to their clergy.

The word is derived by some from the Latin *erogare*, to give, or distribute; according to others from *rogo*, I ask; hence, say they, it is that St. Gregory the Great calls such distributions *precaria*, as being to be demanded in order to be had. Others, again, derive it from the Greek *ρογα*, sometimes used for *corn*; because it anciently consisted in corn, distributed among the populace, the soldiery, &c.

The emperors used to distribute these *rogæ* on the first day of the year, or on their birth-day, or on the natalis dies of the cities. The popes and patriarchs in Paschal Week.

This custom of *rogæ*, or largesses, was introduced by the tribunes of the people, to gain the populace more effectually over to their interest. The emperors at length took it up, and made such distributions to the people, and even to the soldiery, who are hence called by the Greek writers of the middle age *ρογαλοποις*.

**ROGA** is also used for the ordinary pay of the soldiery.

**ROGA-**

**ROGANELLO**, in *Geography*, a river of Naples, which runs into the gulf of Tarento, near Civita Mendrino.

**ROGATCHEV**, a town of Russia, in the government of Mogilev, on the Dnieper; 76 miles S. of Mogilev. N. lat. 52° 36'. E. long. 30° 14'.

**ROGATIO**, **ROGATION**, in the *Roman Jurisprudence*, a demand made by the consuls, or the tribunes, of the Roman people, when a law was proposed to be passed.

The demand was made in these terms: *Do you will and appoint that (for instance) war be declared against Philip?* This was the *rogatio*; and what the people returned in answer, as, *The Roman people do appoint war to be made against Philip*, was the *decretum*, *decree*, or *resolve*.

The word *rogatio* is frequently also used for the decree itself, to distinguish it from a *senatus-consultum*, or decree of the senate.

Frequently, also, *rogatio* is used in the same sense with *law*, because there never were any laws established among the Romans, but what was done by this kind of rogation. Otherwise they were null.

**ROGATION WEEK**, the week immediately preceding Whit Sunday; thus called from three fasts therein; viz. on the Monday, Tuesday, and Wednesday, before Holy Thursday, or the Ascension of our Lord; called also *Rogations*, or *Rogation days*, because of the extraordinary prayers, and processions then made, for the fruits of the earth.

Dr. Godolphin says, the Rogation days derive their name from certain ordinances for abstinence, or days of fasting, which the bishop of Rome recommended to be observed by the Western churches, before he assumed the power of compulsion; and which he, therefore, called by the gentle name of *Rogation*, the time of abstinence being appointed at the beginning by that ordinance, which was called *Rogatio*, and not *lex*, or *decretum*.

The first who appointed these rogations was St. Mamertus, bishop of Vienne, who, in 474, assembled several bishops, to implore the mercy of God by a fast of three days, on occasion of an incursion then made into the country by a number of wild beasts. Others say, it was first set on foot by the same Mamertus, in 463, on occasion of some great public calamities.

His example was soon followed, first by the church of Clermont, in Auvergne, then by all their neighbours, and afterwards throughout all Gaul.

In 801, Leo III. confirmed this fast, and made it universal.

**ROGATORES**, among the Romans, those who in the comitia centuriata brought the chest into which the people threw the ballots containing their votes.

**ROGE**, in *Geography*, a town of Sweden, in the province of Skone; 28 miles N.W. of Christianstadt.

**ROGEHAUSEN**, a town of Prussia, in the palatinate of Culm; 21 miles N.E. of Culm.

**ROGELGRUBE**, a town of Prussia, in the Frische Nerung; 15 miles N.W. of Elbing.

**ROGELIM**, in *Scripture Geography*, a place of Judea, in the tribe of Gad, the residence of Barzillai; mentioned in the book of Kings.

**ROGER**, in *Biography*, first king of Sicily, born in 1097, was son of Roger, count of Sicily, and grandson of the Norman Tancred of Hauteville. He succeeded in his fourth year to the sovereignty of Sicily, under the guardianship of his mother Adelaide. As soon as he assumed the reins of government, he endeavoured to obtain the undivided possession of Palermo, of which a half belonged to

the elder branch of his family, and also to enlarge the bounds of his estates in Calabria. On the death of his relation, William, duke of Apulia, he was proclaimed at Reggio duke of Apulia and Calabria; but the pope, Honorius II., refused for some time to grant him an investiture to those duchies; at length, however, an accommodation was effected, and the pope became his friend. He was now a powerful prince, and being urged by some of his subjects to assume the regal title, he readily complied with their wishes. In 1130 he convoked an assembly of his barons at Palermo, and received with great pomp and ceremony the royal crown of Sicily from the hands of a cardinal, delegated for the purpose. He was invested at the same time with the principality of Capua and the dukedom of Naples. A rebellion broke out among his new subjects in Italy, which obliged him to retire to Salerno, and thence to Sicily. Roger, at this period, had espoused the cause of Anacletus, while the emperor Lothaire had espoused the cause of Innocent II., who was likewise acknowledged by several of the Italian states. A formidable confederacy was formed against Roger, in which the republic of Pisa, then a powerful maritime state, took a leading part. An active war was carried on for several years with various success in the south of Italy. In 1137 the emperor reduced the whole of Apulia, of which a new duke was created, while Roger was excommunicated by Innocent II. In 1139 he took the pope prisoner, who was obliged to purchase his liberty by the absolution of the king, and his investiture in Sicily, Apulia, and Capua. From this period the affairs of Roger became prosperous, and the successors of Innocent, who had refused to acknowledge his regal title, were brought to comply by the terror of his arms. About the year 1146, Roger carried his arms into Africa, and after reducing Malta, which from this period was annexed to the crown of Sicily, he made himself master of Tripoli, Tunis, and other extensive tracks along the sea-coast, which he rendered tributary. About the same time he avenged himself of the injustice of the Greek emperor, Manuel, who had imprisoned his ambassadors, and offered him other indignities, by sending a powerful fleet, which took the island of Corfu, and cruelly ravaged the coast of Morea. One result of this expedition was, the carrying off a number of silk manufacturers, and settling them in Apulia and Sicily, where they introduced their art. His admiral advanced as far as Constantinople, the suburbs of which he pillaged and burnt; and he had the honour of setting at liberty Lewis VII. of France, who, on his return from the Holy Land, had been intercepted by a Grecian squadron. Manuel, however, assisted by the Venetians, pursued and in part destroyed the Sicilian fleet, and recovered Corfu. Roger now associated his only surviving son with him on the throne, and after employing the last years of his life in erecting monuments of his munificence and piety, he expired at Palermo in the year 1154, in the 58th year of his age, and 25th of his reign as king, leaving the character of one of the ablest, most vigorous, and fortunate princes of his time. Gibbon, vol. x. Mod. Univer. Hist.

**ROGER DE HOVEDEN**, a learned historian of the 13th century, was probably born at the town of Hoveden or Howden, in Yorkshire, some time in the reign of Henry I. Having received the early parts of his education, he began to study the civil and canon law, which were then become the most fashionable branches of learning. He was appointed domestic chaplain to Henry II., who employed him in many ecclesiastical affairs, in which he acquitted himself with high honour. He is, however, best known by his *Annals of England*, from the year 731, where Bede's Ecclesiastical

History ends, to 1202. This work, which is one of the most voluminous of our ancient histories, is more valuable for the sincerity with which it is written, and the great variety of facts which it contains, than for the neatness of its style, or the regularity of its arrangement.

ROGERS, JOHN, an English divine, was educated at Cambridge, and became chaplain to the factory at Antwerp, where he assisted Tindal and Coverdale in translating the Bible into English. In the reign of Edward VI. he returned to England, and obtained a prebend in St. Paul's cathedral, where he was a frequent and zealous preacher. He was the first person executed in the reign of the bloody Mary, being burnt in Smithfield in 1555. In the former reign he had been, at least, an abettor of the same sort of persecution of which he himself became the victim. This fact deserves to be recorded. When the Protestant bishops had determined to burn Joan of Kent, a friend of Rogers, the divinity reader in St. Paul's church, came to him, earnestly desiring him to use his interest with the archbishop, that the poor woman's life might be spared, and other means used to prevent the spreading of her opinions, which might be done in time; urging, though that while she lived she infected few with her opinion, yet she might bring many to think well of it by suffering death for it; he pleaded, therefore, that it was better she should be kept in some prison, without an opportunity of propagating her notions among weak people; and so she would do no harm to others, and might live to repent herself. Rogers on the other hand pleaded, she ought to be put to death. Well then, says his friend, if you are resolved to put an end to her life, together with her opinions, choose some other kind of death more agreeable to the gentleness and mercy prescribed in the Gospel, there being no need that such tormenting deaths should be taken up in imitation of the Papists. Rogers answered, that burning alive was no cruel death, but easy enough. His friend, then hearing these words, which expressed so little regard to the poor creature's sufferings, answered him with great vehemence, and striking Rogers's hand, which he before held fast, said to him, "Well, it may perhaps so happen, that you yourselves shall have your hands full of that mild burning." And so it came to pass. Mr. Pierce, who has recorded this anecdote, conjectures with great probability, that the friend of Rogers was the historian himself.

ROGERS, captain Wood, a famous English navigator in the early part of the eighteenth century, of whose private history little is known, failed in the Duke, a private ship of war, of 30 guns and 170 men, in company with the *Duchess*, a smaller vessel, commanded by captain Stephen Courtney, on an expedition into the South seas against the Spaniards. These ships were fitted out by a company of merchants at Bristol, and they set sail on the 1st of August, 1708. On board one of them as pilot was the afterwards celebrated captain DAMPIER, (see his article.) In passing the straits of Magellan, they not only captured several ships, but likewise took several towns upon the coast, and on the 22d of December 1709, they met with the famous Acapulco ship, which was the lesser of two ships, which at that period sailed annually from the East Indies to Mexico. She carried 20 guns, and would not surrender until she was overcome: an action began and lasted about half an hour, when the Spaniard hauled down her colours; and she was found to be a most valuable prize, worth 2,000,000 pieces of eight. After this they met with the larger Acapulco ship, but having skirmished two days, they found it impossible to capture her. They therefore deter-

mined to return by the East Indies, and arrived in the Downs after having circumnavigated the globe, on the 2d of October, 1711. This voyage, which was abundantly successful, led to the foundation of the SOUTH SEA COMPANY; which see. In 1718, captain Rogers having been appointed governor of the Bahama islands, proved himself well adapted to the situation, by the vigorous measures which he adopted against the pirates, who had become most inimical to the trading interests of the country. He arrived at Providence, after a short and easy passage, on the 11th of April, took possession of the town of Nassau, and the whole island, much to the satisfaction of the inhabitants, and many of the pirates, who had settled themselves there, submitted at once to his authority. He proceeded soon after in forming a council, and settling the government of those islands, appointing civil and military officers, raising militia, and taking every other step necessary for procuring safety at home, and security from any thing that might be attempted from abroad, in which by degrees he completely succeeded. Some of the pirates at first rejected the terms, and continued to do a good deal of mischief on the coast of Carolina; but when they saw that captain Rogers had thoroughly settled himself at Providence, and was not to be trifled with, and that the inhabitants of the Bahamas found it to be to their interest to be honest, they thought proper to solicit mercy; so that by the 1st of July, 1719, there were not above three or four vessels of those pirates which continued to trade, two of these being captured, and their crews executed, the rest dispersed. "Thus," says the judicious Campbell, "in a short time, and chiefly through the steady and prudent conduct of governor Rogers, this herd of villains was in some measure dissolved, who for many years had frightened the West Indies and the northern colonies, coming at last to be so strong that few merchantmen were safe, and withal so cruel, that slavery among the Turks was preferable to falling into their hands." See Campbell's Lives of the Admirals, Stockdale's edition, vols. iii. and iv.

ROGERS, BENJAMIN, doctor of music, an ecclesiastical composer, whose works are still contained in our cathedral service, and for whose fame Anthony Wood has manifested great zeal. This musician was born at Windsor, and brought up in that college under Dr. Nath. Giles; being employed there, first as a singing boy, and afterwards in the capacity of lay clerk or singing man. Thence he went to Ireland, and was appointed organist of Christ-church in Dublin, where he continued till the breaking out of the rebellion, in 1641; at which time, being forced to quit his station, he returned to Windsor, where he was again reinstated as choirman; but being soon after silenced in consequence of the civil wars, he procured a subsistence by teaching in the neighbourhood. And during this time, according to his friend Ant. Wood, having addicted himself much to study, he acquired great credit as a composer, and produced several sets of airs in four parts for violins and an organ, which being then imagined the best that could be composed of that kind, were sent as great rarities to the archduke Leopold, afterwards emperor, and himself a great musician; and, upon their being performed by his band, they were very much admired.

In 1658, by the favour of his friend Dr. Ingelo, he obtained the degree of bachelor in music at Cambridge, and acquired great reputation in that university by his exercise. Soon after, on Dr. Ingelo going chaplain to Bulltrode lord Whitelock, into Sweden, he carried with him some of Ben. Rogers's best compositions, which, upon being repeatedly

peatedly performed in the presence of Christiana, queen of Sweden, were very much applauded.

At the Restoration he was appointed to compose the music that was performed at Guildhall, on the day his majesty and his brothers, the dukes of York and Gloucester, dined there with the lord mayor, by which he greatly increased his reputation.

About this time he was chosen organist of Eton college, which he resigned soon after, on being invited to Oxford, where he was appointed to the same office in Magdalen college. And in 1669, upon opening the new theatre in that city, he was created doctor in music. He continued, says Ant. Wood, in the university, where he was much esteemed, till the year 1685, when he was ejected, in company with the fellows of his college, by king James II. after which he long resided in the skirts of the town, wholly disregarded.

"His compositions for instruments," says Ant. Wood, "whether in two, three, or four parts, have been highly valued, and were thirty years ago always first called for, taken out and played as well in the public music schools, as in private chambers: and Dr. Wilson, the professor, (the greatest and most curious judge of music that ever was,) usually wept when he heard them well performed, as being wrapt up in an ecstasy; or, if you will, melted down: while others smiled, or had their hands and eyes lifted up, at the excellence of them."

It is to be feared, that instead of *weeping*, the wicked lovers of modern music would now *laugh*, if they were to hear the quaint and starchy strains, and see on paper the ruffs and roll-ups of honest Ben. Rogers at the Opera-house, or professional concert, Hanover-square. But, alas! what is the secular music, that thirty years have not wrinkled, withered, and rendered superannuated!

ROGERS'S POINT, in *Geography*, a cape on the W. side of lake Huron. N. lat. 44° 19'. W. long. 82° 45'.

ROGERSVILLE, the chief town of Hawkins county, in the state of Tennessee, pleasantly situated in Carter's valley, with a prospect agreeably variegated by some round hills at a distance. It contains about 20 dwelling-houses, some public buildings, stores, &c. It has a number of perennial springs, and one above the level of the streets.

ROGETS, a town of the duchy of Magdeburg, at the conflux of the Oura and Elbe; 16 miles N. of Magdeburg.

ROGGENDORF, a town of Austria; 8 miles W. of Aggspach.

ROGGEWELD, a transmontane division of the district of Stellenbosch and Drakenstein, at the Cape of Good Hope, called the Rye-grass country, and divided into Upper, Middle and Little. These are the summit of a long extended Table mountain, whose western front rises out of the Karroo plains, behind the Bokkeweld, almost perpendicularly, to the height of two or three thousand feet. Stretching to the eastward, this summit becomes more broken into inequalities of surface, and rises at length into the mountains of Nieuweld, the Camdeboo, and the Secuwberg, which may be considered as one extended chain. The great elevation of the Roggeweld, and its being surrounded by the Karroo plains, make the temperature in winter so cold, that for four months in the year, the inhabitants are under the necessity of descending to the feet of the mountains, with their horses, cattle, and sheep. The strongest and largest breed of horses in the whole colony is that of the Roggeweld. See NIEUWELD.

ROGIERS, a town of France, in the department of the Var; 4 miles S. of St. Maximin.

ROGLIANO, a town of Naples, in Calabria Citra; 9 miles S.S.E. of Cosenza.—Alfo, a town of the island of Corfica; 20 miles N. of Baltia.

ROGME, in *Surgery*, a rupture or fracture.

ROGNES, in *Geography*, a town of France, in the department of the Mouths of the Rhone; 13 miles N.W. of Aix.

ROGO, an island of Sweden, near the E. coast, in the Baltic. N. lat. 57° 53'. E. long. 16° 36'.

ROGONATGUNGE, a town of Bengal; 30 miles S.W. of Rogonatpour. N. lat. 23° 17'. E. long. 86° 21'.

ROGONATPOUR, a town of Bengal, and capital of the circar of Pachete; 150 miles S.S.E. of Patna. N. lat. 23° 33'. E. long. 85° 44'.—Alfo, a town of Bengal; 31 miles S.E. of Kishenagur.

ROGOSNO, a town of the duchy of Warsaw; 16 miles N. of Posen.

ROGOWA, a town of Prussia, in the palatinate of Culm; 7 miles E. of Thorn.

ROGSTA, a town of Sweden, in Helsingland; 2 miles N.E. of Hudwickwall.

ROGUE, in *Law*, an idle and sturdy beggar, who, by ancient statutes, for the first offence, is called a *rogue of the first degree*, and punished by whipping, and boring through the gristle of the right ear, with a hot iron, an inch in compass; and, for the second offence, is called a *rogue of the second degree*, and ordered to be put to death as a felon, if he be above eighteen years of age. For the description and punishment of rogues, as they are established by 17 Geo. II. cap. 5, see VAGABOND.

ROGUES, or *Whores' March*, in *Military Language*, a beat of the drum, accompanied by the fifes, when a soldier is drummed out of the regiment, or common prostitutes are drummed out of camp or garrison.

ROGUES TARN, a name given to a rope-yarn, which is placed in the middle of every strand, in all cables and cordage in the king's service. It differs from all the rest, as being untarred and twisted in a contrary manner, by which it is easily discovered. The use of this contrivance is to examine whether any cordage, supposed to be stolen or embezzled, has been formed for the king's service, the possessor of which is subject to a heavy fine. Falconer.

ROGUINS, in *Geography*, a town of France, in the department of the Rhone and Loire; 6 miles E. of Roanne.

ROGUN, a town of European Turkey, in Albania; 6 miles W.N.W. of Arta.

ROHACZOW, a town of Lithuania, in the palatinate of Minsk, on the Dnieper; 85 miles S.E. of Minsk. N. lat. 52° 50'. E. long. 29° 33'.

ROHALE, a small island on the W. side of the gulf of Bothnia, N. lat. 60° 37'. E. long. 17° 49'.

ROHAN, HENRY, *duke of*, in *Biography*, second of the name, but one of the first rank, talents, and character of the French nobility of his time, was born in 1579, at the castle of Blein, in Brittany. At the age of sixteen he distinguished himself at the siege of Amiens, under the eye of Henry IV., to whom he was presumptive heir, before the birth of the dauphin. After the death of Henry, he was at the head of the Calvinist party in France, a station which he retained during three religious wars against the authority of Lewis XIII. In the first, in 1621, he defended Montauban in person: the siege was raised, and in the following year a favourable peace was granted to the Protestants. The war was rekindled in 1625, but was soon terminated by a peace. At length Richelieu resolved entirely to subdue a party which had become a sort of separate republic

in France, allied for its own defence with her enemies. He besieged and took Rochelle, the strong hold of the Calvinists; and though the duke of Rohan vigorously maintained the war in Languedoc, he was at length obliged, in 1629, to make his submission, and the party was deprived of all its fortresses, but still allowed the public exercise of its religion. To some of the most violent, who were enraged at the terms of accommodation, and accused their chief of having sold them, he presented his naked breast, saying, "strike! I am content to die by your hands, after having ventured my life in your service." As it was one of the conditions that he should quit the kingdom till it pleased the king to recall him, he retired to Venice, and it is affirmed, that, during his residence in that city, the duke engaged in a negotiation with the Ottoman Porte, for the purchase of the island of Cyprus, with a view of settling in it Protestant refugees from France and Germany, and that it failed principally through the death of the patriarch Cyril, by whose mediation it was carried on. The Venetian republic nominated him its general in chief against the Imperialists; but the king of France took him from its service to send him ambassador to the Swiss and Grisons. At the head of the troops of the latter, he drove the Germans and Spaniards out of the Valtelline in 1633. He after this defeated the Spaniards on the banks of the lake Como, but the Grisons becoming suspicious that it was not intended to withdraw the French troops from their country, rose in arms, and the duke was obliged to make a separate treaty with them in 1637. He now retired to Geneva, and from thence went to join his friend, the duke of Saxe-Weimar, with whom he fought against the Imperialists at Rheinfeld, in 1638. He was severely wounded in the action, and died some weeks after, at the abbey of Konigfeld, in Switzerland, at the age of fifty-nine. His body was interred in the church of St. Peter, at Geneva, where a magnificent monument was erected to his memory. The duke was author of several works, military and political. These are, "Les Intérêts des Princes;" "Le parfait Capitaine, ou l'abrégé des Commentaires de César;" "Un Traité de la Corruption de la Milice ancienne;" "Un Traité du Gouvernement des Treize Cantons;" "Memoires," containing the transactions in France from 1610 to 1629; "Recueil des quelque Discours politiques sur les Affaires de l'Etat, depuis 1612 jusqu'en 1629;" "Memoires et Lettres de Henri, duc de Rohan, sur la Guerre de la Valtelin." The duke was one of the greatest captains of his time, and possessed all the qualities requisite in the head of a party, together with disinterestedness, generosity, and gentleness of manners. His wife, Margaret of Bethune, daughter of the great duke of Sully, warmly espoused the interests of her husband and party, and was greatly celebrated for her courage. His brother also, Benjamin de Rohan, lord of Soubise, acted a distinguished part in the Calvinist wars, and finally took refuge in England, where he died in 1690.

ROIHAN, in *Geography*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of Plœrmel; 10 miles N.W. of Josselin. The place contains 422, and the canton 9951 inhabitants, on a territory of 267½ kilometres, in 9 communes. N. lat. 48° 6'. W. long. 2° 40'.

ROHAN-ROHAN, a town of France, in the department of the Two Seves; 6 miles S.S.W. of Niort.

ROHAULT, JAMES, in *Biography*, a French philosopher and mathematician, was born at Amiens, in Picardy, in 1620. Having received the early part of his education at his native place, he was sent to Paris, to study mathematics and philosophy. In his enquiries he appears to have been

possessed of an ardent love of truth, and to have fought after it with the utmost diligence and impartiality. He studied both the ancients and moderns, but Des Cartes was the author which engaged most of his notice, and of that celebrated philosopher he became a zealous follower. His attachment to the system of Des Cartes introduced him to the acquaintance of Claude Clerfelier, who gave him his daughter in marriage, in opposition to the remonstrances of his family. He engaged his son-in-law to draw up an abridgment and explanation of the philosophical works of Des Cartes, and to illustrate the same with notes. The result of his labours, which he entitled "Physics," was taught by him at Paris, during ten or twelve years before he gave it to the public. Rohault died in the year 1675, at the age of fifty-five, leaving behind him the character of an amiable, as well as very learned man. His Physics were translated from the French into Latin by Dr. Samuel Clarke, who accompanied his version with notes that overset the system of Des Cartes, in order to make way for that of the illustrious sir Isaac Newton. The best edition of this translation is that of 1718. Rohault also published "Elements of Mathematics," and "Dialogues concerning Philosophy;" and after the author's death, a collection of pieces was made from his manuscripts, and printed first at Paris, and afterwards at the Hague, in 1690, in two vols. 12mo. containing the first books of Euclid, Trigonometry, Practical Geometry, Fortification, Mechanics, Perspective, &c.

ROHBA, in *Geography*, a town of Arabia, in the province of Hedsjas; 10 miles S. of Vadelkora.

ROHEETA, a town of Hindoostan, in the circar of Gohud; 20 miles S.E. of Gohud.

ROHILCUND, or ROHILLA, a circar or province of Hindoostan, situated on the E. side of the Ganges, and N.W. of the subah of Oude. The territory of the Rohillas was formerly called Catheir, and recently derived its name from the conquerors of that tribe, who, about the year 1720, left Afghanistan, and the mountains which they occupied between India and Persia, and came thither in pursuit of military service. These emigrants were first entertained by Madar Saha, the Hindoo chief of Serowly, a small town in the N.W. quarter of Rohilcund, who, by robbery and predatory excursions, maintained a large party of banditti. Some time afterwards, the Rohillas quarrelled with Madar Saha, and associated with the chief of Bareilly; but, separating from this chief, they made incursions into the territory of the rajah of Kemaon. In this expedition they at first succeeded, but were afterwards defeated; their leader, who was an original emigrant from Afghanistan, being taken prisoner and put to death. After his death, his associate, Ali Mahomet, a youth of the sect of Jats, whom he had captured in one of his excursions, and brought up in the Mahometan religion, became the chief of the party; and being brave and enterprising, though young, he availed himself of every opportunity that occurred for advancing his power, and enlarging his territory. Ali, chiefly by the assistance of the vizier Kummer ud Dein, obtained a commission for collecting the revenue of the pension land, which, it is said, he punctually remitted. From this period we may date the first establishment of the Rohilla power in Rohilcund, the name by which they distinguished the Cuttera or Kutterah districts, and their other territories on the east side of the Ganges. Ali Mahomet fixed his residence at Owlah, and established throughout his territory a permanent system of government, which, though occasionally rigorous, afforded protection to the lower class of people. In process of time, and in consequence of several predatory acts which he committed, Ali was attacked by the prince Mahomet Shah,

Shah, who entered Rohilcund with a powerful armament, and took possession of the open country. At length he was compelled to surrender himself to the king, but by the intercession of Kummer ud Dein he was pardoned. With this event, which happened in the year 1745, the power of the Rohillas was annihilated in Rohilcund; and all their officers and principal people were removed to Delhi. Ali, having remained about a year at Delhi, under the protection of the vizier, was, by his recommendation, appointed the military governor of Sirhind, who, during his residence in this place, was joined by a body of 2000 or 3000 marauding Afghans; so that his party was computed to consist of 10,000 cavalry, and 15,000 or 20,000 infantry, of various denominations. Whilst the Mogul and Afghan armies were preparing for action, he quitted the Panjab and retired to Hurdwar, from whence he penetrated, in 1747, into Rohilcund, which he rapidly conquered, and soon after died at Owlah. The last army that might be reckoned *imperial*, was, in 1749, defeated by the Rohillas; by which their independency was firmly established in the eastern part of the province of Delhi. About the year 1750, the territory which had been personally possessed by Ali Mahomet, was, by the deliberation and agreement of the principal Rohilla officers, divided among his sons. At length, however, Hafiz Ahmed, who possessed military talents, in the exercise of which he had acquired influence in Rohilcund, superseded the authority of Saud Ullah, the third son of Ali Mahomet, and was advanced to the supreme administration of affairs; and at the death of Saud Ullah, which happened at Owlah in 1761, the power of Hafiz was established. The form of government adopted by the Rohillas in India, similar to that which subsisted in their native country, may be denominated feudal. The successors of one of the first invaders, *viz.* Daoud Khan, possessing very moderate hereditary pretensions, and surrounded by persons who had afforded essential assistance in the first conquest, held but a limited sway. Two of the most respectable of the Rohillas never ceased to oppose the progress of Hafiz Rhamut, who aimed at sovereign authority; but zealously attached to the interest of the widow of Saud Ullah, they formed a counterpoise to the encroaching power of that chief. The Afghan conquerors of Rohilcund, were a bold, rapacious, and lawless set of men; and after they had established a kind of government in India, they adopted the more effeminate vices of the south, and became intriguing, deceitful, and treacherous. The Rohillas, particularly those of the lower class, were, with few exceptions, the only Mahometans in India who exercised the profession of husbandry, and their attention to agriculture was amply recompensed by the abundance and superior qualities of the productions of Rohilcund. This country is said to have yielded to the Rohillas one million sterling, a sum which, in later times, has been very considerably reduced. According to Mr. Hamilton, the Rohillas themselves have been the great cause of the ruin of the country which bears their name; it was parcelled out among their chiefs, who had afterwards but a feeble connection with each other; while their dependence on Hafiz (Hafley) Rhamut, their prince, was more nominal than real. In the year 1773 the Mahrattas crossed the Ganges to invade the Rohilla country; but a brigade of the British marched to the western frontier of that country, and drove the Mahrattas across the river. For this protection the Rohilla chiefs had stipulated to pay Sujah Dowlah, nabob of Oude, 40 lacks of rupees; but when this essential service was performed by the British army, which moved as the allies of Sujah Dowlah, the payment of the money was evaded. This breach of treaty led to the invasion

and conquest of the Rohilla country in the following year, 1774; and it was then added to the subah of Oude. Since this conquest, the country has rapidly degenerated into a waste, under the deleterious politics of the ministers of Oude. The natives are said to be a tall, handsome race of people; and when compared with the other inhabitants, are white and well featured. They continued for a considerable time to carry about in triumph some couches and palanqueens of European officers that were killed by their army in the fatal action of 1774, by which we purchased a victory at a greater expence of European lives than was ever suffered by the same number of troops in India. The capital of Rohilcund is *Bereilly* or *Bareilly*, which see. The district of Rampour, situated at the foot of the Northern mountains, and possessed by a Rohilla chief, is included in Rohilcund, but it was secured to Fizzoolah Cawn, the chief, by the treaty of Loldong, in 1774. It is valued at 30 lacks of rupees *per annum*; but he is, in effect, tributary to Oude, (which see,) by being bound to furnish his quota towards an establishment for the common defence.

ROHILLAMOW, a town of Hindoostan, in Oude; 21 miles S.S.E. of Kairabad.

ROHINI, in *Astronomy*, the Sanskrit name of a star, supposed to be that designated on our globes by  $\alpha$  Tauri. In mythology it is an asterism that furnishes more poetical allusion than any other in the zodiac. Rohini is one of the sixty daughters of Daksha, and one of the twenty-seven espoused by Soma, or the moon; the lunar regent being male among the Hindoos, as it is with some European mythologists. (See SOMA.) Under the article NAKSHATRA, which means the asterisms marking the moon's path, mention is made of the poetical derivations from this fruitful source, and we will here add another instance of it, relating to Rohini, the favourite consort of the sickle Soma. In one of their terrestrial journies, arriving at the southern mountain Sahyadri, they unwarily entered the forest of Gauri, or Parvati, where some men, having formerly surprised Mahadeva caring for that goddess, they were punished by a change of their sex, and the forest had retained a power of effecting a like change on all males who should enter it. Soma, or Chandra, instantly becoming a female, (Chandri,) was so afflicted and ashamed, that she hastened far to the well, sending Rohini to her seat in the sky, and concealed herself in a mountain, afterwards named Somagiri, where she performed acts of the most rigorous devotion. Darknefs then covered the world each night, the fruits of the earth were destroyed, and the universe was in such dismay, that the Devas, or divinities, with Brahma at their head, implored the assistance of Mahadeva, who, placing Chandri on his head, she became male again. Mahadeva, in statues and pictures, is usually seen with the moon on his head and forehead, and one of his names is Chandra-sektra, or *moon-crowned*. (See SIVA.) Another fable states that she was visited in her retreat by Surya, or the sun, from which conjunction arose a numerous progeny. Mahadeva is the sun; and this sol-lunarian progeny is, perhaps, vegetation. Under the article ILLA is another lunarian fable, probably connected with these. Siva's spouse, Parvati, is as jealous as Juno.

These fables, taken from the Asiatic Researches, vol. iii. are related by Mr. Wilford, from Puranic authority; and were thus explained to him by an ingenious Pandit. To the inhabitant of the countries near the source of the Kali, or Nile, the moon, being in the mansion of Rohini, or the Pleiades, seemed to vanish behind the southern mountains. Now when the moon is in opposition to the sun, it is the god Chandra; in conjunction, the goddess Chandri. The moon is believed, by Hindoo naturalists, to have a power-

ful influence on vegetation, especially on certain plants, and, above all, on the Somalata, or moon-plant. (See SOMALATA.) This mode of interpretation, Mr. Wilford adds, may serve as a clue to the intricate labyrinth of the Puranas, which contain all the history, physiology, and science of the Indians and Egyptians, disguised under similar fables. See PURANA.

ROHITZ, in *Geography*, a town of Stiria, in which is a medicinal spring; 20 miles E. of Cilley.

ROHL, a small island in the gulf of Finland. N. lat. 59° 55'. E. long. 26° 26'.

ROHLA, a river of Bohemia, which runs into the Egra, near Carlsbad.

ROHN, a town of Germany, in the county of Henneberg; two miles N.N.W. of Salzungen.

ROHN. See PULO Ron, and POOLARON.

ROHND, a town of Bengal; 15 miles N. of Torce.

ROHOB, a town of Judea, in the tribe of Asher, mentioned in the books of Joshua and Numbers. To this place Moses sent twelve men to reconnoitre the land of promise. It was assigned to the Levites of the family of Gershon.

ROHOSSETZ, a town of Bohemia, in the circle of Boleslaw; eight miles N.W. of Turnau.

ROHR, a town of the duchy of Stiria; nine miles W. of Gnaa.—Also, a river of the duchy of Bremen, which runs into the Weser near Carlsburg.—Also, a town of Germany, in the principality of Culmbach; five miles S.E. of Culmbach.—Also, a town of Germany, in the county of Henneberg; two miles E. of Meinungen.

ROHR, *Inn*, a town of Austria; 10 miles N.W. of Neustadt.

ROHRBACH, a town of Germany, belonging to the priory of Odenheim; 10 miles W. of Heilbronn.

ROHRBECK, a town of Saxony, in the principality of Querfurt; two miles S. of Juterbock.

ROHRIA, in *Botany*, a genus of Schreber's, has been supposed, by De Theis, to commemorate Julius Bernard von Rohr, a German botanical writer of the middle of the 18th century, whose works are little known out of his own country. We rather presume, with professor Martyn, that the author of this name had in view a more recent, and very eminent, practical botanist, long resident in South America, Julius Philip Benjamin von Rohr, perhaps a relation of the former, whose discoveries are often mentioned by Vahl, and who has written on *Quassia amara*, the culture of Cotton, and other subjects. Thunberg has also a *Robria*, adopted from Vahl; which having been previously called *Berckbeya*, by Ehrhart, is now retained under the latter name in Willd. Sp. Pl. v. 3. 2269.—Schreb. Gen. 30. Willd. Sp. Pl. v. 1. 186. Mart. Mill. Dict. v. 4. (Tapura? Aubl. Guian. v. 1. 126. Juss. 419. Lamarck Illustr. t. 122.)—Class and order, *Triandria Monogynia*. Nat. Ord. uncertain, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, in five deep, ovate, concave, obtuse, fringed, coriaceous segments, the two interior ones rather longest. *Cor.* Petals five, erect, longer than the calyx, the two uppermost rather largest, the three lower smallest; claws narrow, dilated at the base, woolly on the inside, a little bent outwards under the border; which in each petal is ovate, erect; in the larger petals hooded inwards; in the smaller expanded and bluntish. *Stam.* Filaments three, one between the two larger petals, two at their sides, connected below with their claws, all thread-shaped, longer than the corolla, woolly at the inside; anthers roundish, erect, directed inwards. *Pist.* Germen superior, turbinate, downy; style thread-shaped,

villous, the length of the stamens; stigmas three, revolute. *Peric.* and *Seeds* unknown.

Eff. Ch. Calyx bell-shaped, in five deep segments. Petals five, unequal. Stigmas three, revolute.

Obf. Schreber doubted whether his plant were the same with Aublet's, because the latter describes the corolla as monopetalous, and the three long stamens as accompanied by two short ones besides. This last circumstance may be accidental; the corolla seems more material. The flowers however are so minute, that Schreber, having seen them in a dried state only, might easily be mistaken. As he is the author of the name *Robria*, we prefer his description, as Aublet's plant, if different, must have another generic appellation.

1. *R. petioliflora*. Willd. n. 1. (Tapura guianensis; Aubl. Guian. v. 1. 126. t. 48?)—The plant of Aublet was found in forests, near the Serpent mountain, in Guiana, flowering in August. It is a shrub, 12 feet, or more, in height, with many flexible, roundish, smooth branches. Leaves alternate, on short thick stalks, elliptic-lanceolate, pointed, entire, smooth and shining, about four inches long; paler beneath. Of *stipulas* we can perceive no traces in Aublet's specimen, except a slight intrafoliate abrupt border. Flowers yellow, small, five, seven, or more together, on very short stalks, springing from the summit of each footstalk, at the base of the leaf.

We presume Schreber received his specimens from von Rohr; and as they agreed with Aublet's in the very remarkable mode of inflorescence, and must have come from the same country, there can be little reason to suspect any real difference.

ROI *des Violons*, or king of the fiddlers, in France. Each profession, or incorporated company, had formerly a superior, who was dignified with the title of king. The masons, carpenters, barbers, lawyers' clerks, cross-bow-men, the principal soldiers called *ribauds*, even the poets, and many other orders of men, had their particular kings; but their exactions and tyranny, by degrees, occasioned the abolition of these phantoms of sovereignty.

The minstrels, religious observers of ancient usages, were the last to relinquish this precious relic of antiquity. The king at arms, and king of the minstrels, were the only surviving monarchs of their calling. But the first has few tributaries, and his functions are only exercised occasionally; the other, on the contrary, was always in power, and pretended to exercise his empire over the whole realm.

The history of the first kings of the minstrels is unknown; it is only recorded that, after the decease of Constantine, the famous violin of the 17th century, the crown passed, in 1630, to Dummoir I., then to Dummoir II., who relinquished the crown by a voluntary abdication, occasioned by an anarchy, in 1685. Louis XIV. saw with indifference the extinction of this royalty, and declared that it was not his intention it should be restored.

This monarchy had been long agitated by internal troubles, and civil and foreign wars. The dancing-masters, originally incorporated with this company, had been 50 years soliciting its extinction; indignant at being united with such vile artisans, who dishonoured their faculty by playing at ale-houses (cabarets) and places of debauchery; or if not totally silenced, that one of the strings of their fiddles should be cut off, and they reduced to their ancient level, and be allowed to play on no instrument but the three-stringed rebec.

They had commenced a suit against the city dancing-masters, and obtained a solemn sentence against them, January 14th, 1667. No company was ever more discordant,

more tumultuous; all the courts of justice rang with their divisions and quarrels, by which the law was enriched, and the public amused, at their expence. The interregnum lasted from 1685 to 1741, when the celebrated Guignon, the violinist, was ambitious of having the royalty revived in his favour. The king had the goodness to comply with his request, and honoured him with the minstrel crown, on the 15th of June the same year. But his election awakening a desire to revive certain prerogatives, which he pretended to be inherent in his crown, he had suits and actions to defend against a host of musicians, particularly the organists, who obtained a complete victory; and Guignon, willing to give a proof of his love for the arts and disinterestedness, generously, and voluntarily, resigned his sovereignty of king of the minstrels.

ROIDALK, in *Geography*, a town of Norway; 48 miles N.N.E. of Stavanger.

ROIHA. See OURFA.

ROIOC, in *Botany*, a barbarous South American, or perhaps Spanish, name, for one of Plumier's genera, rightly referred by other botanists to MORINDA; see that article.

ROISELLE, in *Geography*, a town of France, in the department of the Somme, and chief place of a canton, in the district of Péronne; six miles E.N.E. of Péronne. The place contains 1122, and the canton 14,428 inhabitants, on a territory of 190 kilometres, in 23 communes.

ROKEJECA, in *Botany*, an Arabic name, inadmissible in systematic language, applied by Forskall, Fl. *Ægypt-Arab.* 90, and adopted by Jussieu, Gen. 313, for a supposed genus of the natural order of *Portulacææ*, found in sandy waste ground about Cairo. Jussieu supposes it akin to *Trianthema*. The capsule however is said to have only one cell, and there is a corolla of five petals. We know not that those who have seen Forskall's specimens, have thrown any light on this subject.

ROKETNITZ, a town of Bohemia, in the circle of Königgratz; seven miles N. of Geyersberg.

ROKHAGE. See AROKHAGE.

ROKIT, CAPE, a cape on the N. coast of Africa, at the entrance into the straits of Babelmandeb; 60 miles W. of cape Guardafai.

ROKITNO, a town of Lithuania, in the palatinate of Brzesk; 72 miles E.S.E. of Pinsk.

ROKITZANY, a town of Bohemia, in the circle of Pilsen; eight miles E. of Pilsen.

ROKOL, an isle, or rather large rock, which, according to M. Kerguelen, is situated in N. lat. 57° 50', and long. 16° W. of Paris; or about 5° S.W. of St. Kilda.

ROKOSNIA, a town of Poland, in the palatinate of Braclaw, on the Bog; 16 miles W.N.W. of Braclaw.

ROLAND, DE LA PLATIERE, J. M., in *Biography*, born at Villafranche, near Lyons, of a family distinguished in the profession of the law. He was the youngest of five brothers, left orphans and without fortune. To avoid entering into the church, like his elder brothers, he left home at the age of nineteen, alone, without money, or friends; he traversed a part of France on foot, and arrived at Nantes, intending to embark for India. He was, however, dissuaded from this project, by a merchant who had seen him throw up blood, and who was aware that the climate of the East would infallibly kill him. He accordingly went to Rouen, engaged in the direction of some manufactories; distinguished himself there by his love of study, and his taste for economical and commercial pursuits; and obtained the place of inspector-general at Amiens, and then at Lyons. Having travelled in Italy, Switzerland, and other countries, he accumulated a great mass of valuable information, particu-

larly in what related to the arts, which, on his return, gained him admission into a great number of learned societies. Early in the revolution he became a member of the municipality of Lyons, and founded there a club, which he connected with the Jacobin club of Paris. In 1790 he went to the capital, took a decided share with the popular party, and in March 1792, was raised to the administration of the interior. He seems now to have possessed an enthusiastic love and attachment to a republican form of government. The first day that he appeared before the king, he went with straight undressed hair, a black coat, and shoes without buckles; his behaviour was, at the same time, so very uncourtly, that his majesty dismissed him a very short time before he himself was reduced to scenes of adversity and the most poignant distresses. From this time Roland attached himself more than ever to the Jacobins, and was probably deeply implicated in the business of the 20th of June and 10th of August of that same year. He deprecated, however, the cruelties of the 2d of September, and denounced the horrors that were transacting under the mask of patriotism. As the violent gained ascendancy, Roland was declining in credit. On the 20th of January 1793, he, as member of the provisional executive council, signed the order for the execution of the king: this was one of his last official acts: yielding to the voice of the Mountain faction he resigned, and was involved in the proscription which issued against the Brissotines; but he contrived to escape from Paris, and conceal himself among his friends at Rouen: as soon, however, as he heard of his wife's execution, he determined not to survive her. He stabbed himself near the high road, leaving a paper containing the following lines; "whoever you may be that find me lying here, respect my remains; they are those of a man who devoted his whole life to being useful, and who died, as he lived, virtuous and honest." Roland was kind and obliging to his friends, but the irascibility of his temper made him many enemies. He was deeply read in the learned, and in several modern languages, and was author of the following works: "An Essay on the Rearing of Flocks and the Improvement of Wool;" "The Art of the Woollen-Cloth Printer, of the Cotton-Velvet Maker," &c. This work forms the Compendium of Mechanical Arts, published by the Academy of Sciences. "Letters written from Switzerland, Italy, Sicily, and Malta, in 1782." A new edition of this work was published in 1800. They are addressed to a lady whom he soon after married, and are filled with useful views and interesting accounts of the manufactories of various countries. See the next article.

ROLAND, MARIE-JEANNE PHILEPON, wife of the preceding, was born at Paris in 1754. She was the daughter of an eminent engraver, who, though highly distinguished in his profession, had brought himself to ruin by extravagance and dissipation. The daughter, brought up in the midst of the fine arts, surrounded by books, pictures, and music, became learned and skilled in music and painting. Though not what might be called regularly handsome, her person was attractive, and her character excited general admiration in the circle in which she moved. Her mother dying while she was young, she was obliged, owing to the ruined fortunes of her father, to seek an asylum in a convent. Here she lived in honourable solitude, submitting cheerfully to the privations which were found necessary in her reduced situation, while she took every means to improve her mind by study. In 1780, Roland addressed her, as we have seen, his letters on Italy, and offered her his hand. She accepted the offer, and when married they went to Amiens, where she studied botany, and made an herbal of the plants of Picardy. She afterwards, in 1787, visited Switzerland

and England, and was led, from what she observed in the constitutions of those countries, to study the theory of government, the result of which was an ardent attachment to the principles of liberty. M. Roland having been appointed inspector of the manufactories at Lyons, was deputed to the constituent assembly, to obtain from it succours necessary for the payment of the debt of that town. Madame Roland at this period settled with her husband in the capital, and took delight in receiving at her house the chief of the popular party, and the most distinguished deputies of the Gironde, that is, of the Brissotine party. Brissot, Barbaroux, Louret, Claviere, and Vergniaud, were admitted there; she not only infused ardour into their political deliberations, but is supposed, in many cases, to have been something more than secretary, inditing as well as writing their most celebrated papers: for a time, she was the secret power that directed the whole government of France. In the month of March 1792, when the king found it necessary, in order to allay the public discontents, to nominate a popular administration, Roland was appointed minister of the interior: the principal part of his labours was generally attributed to madame Roland; so much so, that when he resigned, and was urgently pressed by the assembly to resume his functions, Danton exclaimed, "if we give an invitation to Roland, we must give one to his wife too. I know all the virtues of the minister, but we want men who see otherwise than by their wives." According to the memoirs which she wrote of herself, she was in fact the minister without the name: she revised, or perhaps dictated, the letter which Roland addressed to the king on going out of office; "if he had written sermons," said she, "I should have done the same." On the 7th of December 1792, having appeared at the bar of the national convention, to repel a denunciation made against her, she spoke with ease and eloquence, and was afterwards admitted to the honours of a sitting. She presented herself there again, when the decree was passed against her husband; but then, the power of eloquence having lost its charms in the Russian breasts of the senators, she was refused a hearing, and was herself sent to the Abbaye, that dreadful bourn, from whose gate few passed but to a mock-trial and savage execution. From this abode of misery she wrote to the assembly, and to the minister of the interior; her section also demanded for her liberty, but it was in vain; and on the 24th of June 1793, she was sent to the convent of St. Pélagie, which had been converted into a prison, where she passed her time in consoling her fellow prisoners, and composing an account of her own life, and of the transactions of which she had been the eye-witness, and in many of which she had been an actor. At length she was called before the revolutionary tribunal, and underwent an examination with calmness and serenity, disturbed only when one of the ermined savages put to her questions offensive to her modesty. On the 8th of November she was condemned to death for having conspired against the unity and indivisibility of the republic. Her execution immediately followed. On passing the statue of liberty, in the Place de la Revolution, she bent her head towards it, exclaiming, "O Liberty, how many crimes are perpetrated in thy name." Madame Roland was a woman capable of inspiring all the elevated sentiments that she felt; with the grace and animation of one sex, she possessed the firmness and solidity of the other; and she was generally admitted to be superior to all the men of the party with whom her husband acted. She particularly excelled in the penetration and knowledge of the human character. She left one daughter, whose only provision was her mother's writings, which are as follow: "Opuscules," on moral topics, which treat of the soul, melancholy, mo-

ality, old age, friendship, love, retirement, &c.; "Voyage en Angleterre et en Suisse;" and when in prison she composed what she entitled, "Appel à l'impartiale Postérité," containing historical notices, anecdotes, and her own private memoirs. This work presents many well-drawn characters of that period, with the purest sentiments of public and private morality. Her own memoirs are extremely valuable, as giving a picture of life and manners in the middle ranks of life in France, with a view of the progress of a mind which was unquestionably one of the highest order with respect to virtue and intellect. Biog. Moderne, 3 vols. 1814. Biographical Anec. of the Fr. Revol.

ROLAND, or ORLANDO, the poetical hero of Boiardo, Berni, and Ariosto, and nephew of Charlemagne, celebrated in some ancient military songs; for an account of which, see CHANSON. One of these begins with the following verse:

"Let ev'ry valiant son of Gaul  
Sing Roland's deeds, her greatest glory,  
Whose name will stoutest foes appal,  
And feats inspire for future story."

See Burney's Hist. of Music, vol. ii. p. 277.

ROLANDINO, an early Italian historian, was the son of a notary at Padua, in which city he was born, in the year 1200. He studied at Bologna, and in 1220 received the honorary title of master and doctor in grammar and rhetoric. He had kept a chronicle of memorable events as they occurred, and put his papers into his son's hands after he returned from Bologna, with a charge to continue them. This he executed with care and fidelity to the year 1260, when he was urged to revise and complete his work. He employed two years in this revision; and in 1262, his chronicle, in twelve books, in the Latin language, was read publicly before the university of Padua, submitted to an attentive examination, and solemnly approved. Rolandino died in 1276. His history is accounted one of the most exact and faithful records of that time. Though his style is not free from barbarisms, his narrative is clear and well arranged. Vossius affirms, that he surpassed all the writers of his age in perspicuity, order, and judgment, and that he shewed himself well versed in sacred and profane literature. An edition of his work, with other chronicles, was given at Venice in 1636, by Felix Osius, and it has been reprinted by Muratori, in the 7th volume of his Italian historians.

ROLANDRA, in Botany, serves to commemorate Daniel Rolandra, a pupil of Linnæus, who visited Surinam, and communicated an account of the *Doliocarpus* to the Academy of Stockholm, which appeared in the 17th volume of the Transactions of that learned body, published in 1756. Several of his papers on Entomology are to be found in the same collection. He was almost the only naturalist, educated by Linnæus, whose character disappointed the hopes of his preceptor; but he is said to have been still more unfortunate, than negligent or ungrateful. We know no particulars of his history. The name was given by Rottböll, in the Collectanea of the Medical Society at Copenhagen, v. 2. 256. —Schreb. Gen. 593. Willd. Sp. Pl. v. 3. 2400. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 186. Swartz Prodr. 116. Ind. Occ. v. 3. 1388. (See Jusl. 176.)—Clafs and order, *Syngenesia Polygamia-segregata*. Nat. Ord. *Compositæ capitata*, Linn. *Cinurocephalæ*, Jusl.

Gen. Ch. *Common Calyx* none. Florets clustered into a roundish head, the clusters distinct, stalked, separated by numerous, ovate or lanceolate, awned scales, shorter than the florets. Partial perianth chaffy, of two unequal, compressed,

pressed, keeled valves; the upper one largest, awned, enclosing the other, which is pointed. *Cor.* of each floret very minute, of one petal, funnel-shaped; tube long, thread-shaped; limb in five very short, erect, acute segments. *Stam.* Filaments in each floret, five, shorter than the tube; anthers united into a cylinder, below the throat. *Pyl.* Germen, in each floret, triangular, compressed, acute at the base, abrupt at the summit; style the length of the tube, divided at the top; stigmas tumid, erect. *Peric.* none, the seed being enclosed in the unchanged partial calyx. *Seed* triangular, crowned with a toothed border.

*Eff. Ch.* Common Calyx none. Perianth of two valves, single-flowered. Florets all perfect. Seed with a toothed crown.

Obf. Rottböll describes the corolla of each floret as four-cleft; Swartz found it always five-cleft, with five filaments.

1. *R. argentea.* Silver-leaved Rolandra. Swartz Ind. Occ. v. 3. 1389. Willd. n. 1. Ait. n. 1. (*Echinops fruticosus*; Linn. Sp. Pl. ed. 1. 815? *Amaranthoides fruticosus, foliis longis, angustis, subtus niveis*; Sloane Jam. v. 1. 43. t. 7. f. 3.)—Native of Jamaica, Cayenne, and Surinam. Cultivated in Chelsea garden, before the year 1714, and said to flower in the stove in July. We have never met with the living plant. The *stem* is shrubby, erect, branched, round, reddish; the young branches whitish and downy. *Leaves* stalked, alternate, ovato-lanceolate, minutely serrated, about two inches long, ribbed; green and shining, but roughish to the touch, on the upper side; snow-white and downy beneath. There are usually axillary tufts, of a few much smaller leaves. *Flowers* in small, round, sessile, solitary, axillary, whitish heads.—Plumier's *Echinops*, t. 125. f. 1, which Linnæus adopted from him under the name of *fruticosus*, without seeing a specimen, but afterwards rejected, bears too little resemblance to Sloane's plant to be considered, with any probability, as the same.

ROLAS, in *Geography*, a small island in the Atlantic, near the S.W. coast of the island of St. Thomas.

ROLDUC, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Maëstricht; called, in the language of the country, "Hertogenrode," formerly well fortified, but greatly demolished by wars, and the capital of a county, which contained a great number of villages; 10 miles S.W. of Juliers. The place contains 940, and the canton 11,196 inhabitants, on a territory of 100 kilometres, in 12 communes. N. lat. 50° 52'. E. long. 6° 5'.

ROLE, a town of Bengal; 25 miles S.S.E. of Palamow.

ROLEPARA, a town of Hindoostan, in Orissa; 25 miles S.E. of Boad.

ROLL, in the *Manufactories*, something wound and folded up in a cylindrical form.

Few stuffs are made in rolls, except fattins, gauzes, and crapes, which are apt to break, and take plaits not easy to be got out, if folded otherwise. Ribbands, however, and laces, galloons, and paduas of all kinds, are thus rolled.

The ancients made all their books up in form of rolls, or little columns; and, in Cicero's time, the libraries consisted wholly of those rolls. The dearness of parchment, and the cheapness of papyrus, of which the rolls were made, was the reason that scarcely any but paper rolls were used.

Vossius says, they pasted several sheets end to end, when filled on one side, and rolled them up together, beginning with the last, which they called *umbilicus*, and to which they fastened an ivory or boxen stick, to sustain the roll.

To the other extremity they pasted a piece of parchment, to cover and preserve it.

These rolls were placed in the libraries perpendicularly to the horizon. The Jews still preserve the ancient usage of rolls for the books they read in the synagogues.

ROLL, *To*, in *Military Language*, is to continue one uniform beat of the drum, without variations, for a certain length of time. When a line is advancing in full front, or in echellons, for any considerable distance, the music of one regulating battalion may, at intervals, be permitted to play for a few seconds at a time, and the drums of the other battalions may be allowed occasionally to roll: drums likewise roll when troops are advancing to charge. For the method of performing the roll, see *Roll*, under *DRUM*.

ROLL, *Long*, a beat of drum by which troops are assembled at any particular spot of rendezvous or parade.

ROLL, *Short*. See *Ruffle* under *DRUM*.

ROLL of *Tobacco*, is tobacco in the leaf, twisted in the mill, and wound twist over twist, about a stick or roller.

The generality of tobacco in America is there sold in rolls of various weights; and it is not till after its arrival in England, Spain, France, and Holland that it is cut. Roll tobacco is what is chiefly used, both for chewing and rasping. See *TOBACCO*.

ROLL of *Parchment* contains 20 skins.

ROLL, *Rotulus*, in *Law*, denotes a schedule of paper or parchment, which may be wound up by the hand into the fashion of a pipe.

Of these there are, in the Exchequer, several kinds; *viz.* the great *wardrobe-roll*, the *cofferer's-roll*, the *subsidy-roll*, &c.

The word is formed from the French *rolle*, of the Latin *rotulus*; because most instruments and expeditions in law were anciently written on papers, or parchments, sewed or glued together, and thus rolled up: whence the word *enrol*, and the like.

ROLLS of *Parliament*, are the manuscript registers of the proceedings of our ancient parliaments.

Before the use of printing, and till the reign of Henry VII. our statutes were all engrossed in parchment, and (by virtue of the king's writ for that purpose) proclaimed openly in every county.

In these rolls we have also a great many decisions of difficult points in law, which were frequently, in former times, referred to the decision of that high court.

ROLL, *Rider*, a schedule, or small piece of parchment, frequently sewed, or added to some part of a roll, or record.

Noy observes, that the court *ex-officio* may award a certiorari ad informandam conscientiam; and that which is certified shall be annexed to the record, and called a *rider-roll*.

ROLL is also used for a list of the names of several persons of the same condition, or entered in the same engagement.

ROLL, *Court*. See *COURT-Roll*.

ROLL, *Muster*. See *MUSTER-Roll*.

ROLL, *Size*, a list containing the names of all the men belonging to a troop or company, with the height or stature of each specifically marked. Every serjeant keeps a regular size-roll, and every captain of a troop or company ought to have one likewise.

ROLL, *Squad*, a list containing the names of each particular squad. Every non-commissioned officer and corporal, who are entrusted with the care and arrangement of a squad, must have a roll of this kind.

ROLL-*Calling*, is the calling over of the foldiers of a troop, or company, by their names, to see that they are all present.

This necessary duty is performed by the serjeants of companies, morning and evening, in every well-regulated corps. Hence we have "morning roll-call," and "evening roll-call," on critical occasions; and in services that require promptitude and exertion, frequent roll-calls should be made.

ROLL, *Calves-head*, is a roll in the two Temples, in which every bench is taxed yearly at 2s., every barrister at 1s. 6d., and every gentleman under the bar at 1s. to the cook, and other officers of the house, in consideration of a dinner of calves-heads, provided in Easter term.

ROLL, *Ragman's*, or *Ragimund's Roll*, is a roll denominated from *Ragimund*, a papal legate in Scotland; who, calling before him all the people who held benefices in that kingdom, caused them, upon oath, to give in the value of their estates, according to which they were taxed in the court of Rome.

ROLLS, or *Office of Rolls*, in Chancery-lane, London, is an office appointed for the custody of the rolls and records in chancery.

The master of this office is the second person in that court; and, in the absence of the lord chancellor, he sits as judge. See *MASTER of the Rolls*.

This house, or office, was anciently called *Domus Converterforum*, as being appointed, by king Henry III., for the use of converted Jews; but their irregularities occasioned king Edward II. to expel them thence: upon which, the place was deputed for the custody of the rolls.

ROLLS, *Clerk of the*. See *CLERK of the Rolls*.

ROLLS, or *Roul*, among *Military Men*. See *ROUL*.

ROLL, *Bead*. See *BEAD-Roll*.

ROLL, *Check*. See *CHECK-Roll*.

ROLL, *Counter*. See *COUNTER-Roll*.

ROLL, in *Antiquity*. From the time of Anastasius, we find in the hands of the emperors, on medals, a kind of narrow long roll, or fachel; the meaning of which has greatly puzzled the antiquaries.

Some imagine it to be a roll or bundle of papers, memoirs, petitions, &c. presented occasionally to princes, consuls, and the like. Others take it to be a plaited handkerchief, which the persons who presided at the games cast forth as a signal for their beginning. Others will have it a bag of dust and ashes, presented the emperor at the ceremony of his coronation, and called *akakia*, *q. d.* a means of preserving innocence, by the remembrance of dust, &c.

ROLL, or *Roller*, is also a piece of wood, of a cylindrical form, used in the construction of several machines, and in several works and manufactures; though sometimes under other names.

It is on such rolls, properly called *beams*, that the woollen, filken, and other threads are wound, of which the weaver's works consist. For which end, each loom has usually two, and that of the gauze-weavers three.

In the glass manufacture, they have a running-roll, being a thick cylinder of cast brass, serving to conduct the melted glass to the end of the table, on which large looking-glasses are to be cast.

The founders also use a roller to work the sand which they use in making their moulds.

The presses called calenders, as serving to calender stuffs, consist, among other essential parts, of two rollers.

It is also between two rollers that the waves are given to silks, mohairs, and other stuffs proper to be tabbied.

Prints, or impressions, from copper-plates, are also taken by passing the plate and the paper between two rollers. See *Rolling-press* PRINTING, and *COPPER-Plate Work*.

ROLLS, in *Coining*, are two iron instruments, of a cylindrical figure, which serve to draw or stretch out the plates

of gold, silver, and other metals, of which the planks or pieces are to be formed for the species.

ROLLS, in *Printing*, are two large cylinders or barrels of wood fastened in the middle of what they call the cradle or galleys of the press; and which, by means of a cord or girt passing over each, and a handle which gives motion to one of them, draw the carriage of the press backwards and forwards. See *PRINTING*.

ROLLS, in the *Sugar-Works*, are two large iron barrels, which serve to bruise the canes, and express the juice. They are cast hollow, and their cavities are filled up with wood, the cylinders of which are properly the rollers.

ROLLS, or *Rollers*, among *Carpenters*, *Masons*, &c. are plain cylinders of wood, seven or eight inches in diameter, and three or four feet long; used for the removing of beams, huge stones, and other like burdens, which are cumbersome, but not exceedingly heavy.

These rollers are placed, successively, under the fore-part of the masses to be removed; which, at the same time, are pushed forward by levers, &c. applied behind.

ROLLS, *Endles*. When blocks of marble, or other excessive heavy loads, are to be removed, they use what they call *endles* rolls.

These, to give them the greater force, and prevent their burbling, are made of wood joined together by cross-quarters; they are about double the length and thickness of the common roller, and, besides, are girt with several large iron hoops at each end. At a foot's distance from the ends are four mortises, or rather only two, but pierced through and through, into which are put the ends of long levers which the workmen draw by ropes fastened to the ends, still changing the mortise, as the roll has made a quarter of a turn.

ROLL-*rich Stones*, in *Antiquity*, a series of huge stones, ranged in a circle, near Morton in the Marsh, in Oxfordshire. There are many fabulous traditions about them. Among the antiquaries, some take them to be a monument of a victory; others, a burying place; and others, a place for the coronation of the Danish kings.

Near Penros, in Cornwall, is a like monument.

ROLLAND, in *Geography*, an island in the South Indian sea, discovered by Kerguelen in the year 1773, so called by him after the name of the vessel in which he sailed; about nine miles in circuit. N. lat. 48° 37'. E. long. 68° 43'.

ROLLE, MICHAEL, in *Biography*, a French mathematician, was born at Ambert, a small town in Auvergne, in the year 1652. His father was in rather low circumstances, and placed him to gain his livelihood, at first with a notary, and afterwards with different country attornies. Disgusted with an occupation so little suited to his genius, at the age of 23 he went to Paris, depending for his support on his penmanship. At first he taught writing and the early rules of arithmetic: from arithmetic he advanced by gradual steps to algebra, to which he became so enthusiastically attached, that he spent every leisure moment in the study till he became distinguished in that branch of science. In 1682, the learned Ozanam having proposed a difficult mathematical problem to exercise the ingenuity of mathematicians, M. Rolle sent him a very clear solution of it, together with methods which he had invented of solving other problems, attended with still greater difficulty. The minister Colbert, always the patron of talent, having heard of Rolle, determined to draw him out of the obscurity in which he had hitherto been concealed, and settled on him a pension. He now gave up the occupation of a writing master, and devoted himself entirely to the study of algebra, and the other

other branches of pure mathematics; and so great was his success, that in 1685, three years only after his name was first known in the mathematical world, he was chosen a member of the Academy of Sciences. In the year 1690, M. Rolle published a treatise on Algebra, which was followed by a new work, entitled "A Demonstration of a Method for the Resolution of Equations of all degrees;" to which succeeded two other methods; by the first of which the same equations are resolved geometrically; and by the second, several unresolved questions of Diophantus are answered. In the year 1699 he published a work, entitled "A Method of resolving indeterminate Questions in Algebra," and he was appointed second geometrical-pensionary of the Academy of Sciences. About this time he united with that party in the Academy which opposed the new geometry, and carried on a controversy against the marquis de l'Hôpital, on the subject of infinitesimals, till the society imposed silence on all the disputants. M. Rolle thought that his favourite science, algebra, was capable of almost indefinite improvement, and he announced his design of drawing up entirely new elements, but death put an end to his plans. He died in 1719, in the 68th year of his age, having uniformly borne an excellent character for piety, probity, and amiable manners. Besides the works already mentioned, many curious papers were communicated by him to the Academy of Sciences, and may be found in their "Memoirs," from the year in which he took his seat in that body till 1714. The higher branches of the mathematics are the subjects of almost all these papers.

ROLLE, JOHANN HEINRICH, the youngest of three brothers, all eminent musicians, and sons of a father who, as music director at Magdeburg, had rendered the name illustrious. Henry, who succeeded his father as music-director in his native city, was born in 1718, and died in 1785. He was an excellent composer for the church, as well as author of pieces for the organ and harpsichord of great merit. His oratorio of "Thirsa and her Sons," is full of good taste, new passages, pleasing effects, and true pathos.

ROLLE, Fr. a part in *Music and Dramatic Works*. The French have a distinct term in music for a vocal and instrumental part in an opera or concert. The singer's or the actor's part in an opera or play, is equally termed *rolle*; in a concert or opera each instrumental part is called *partie*. We make no distinction, in England, between a vocal or instrumental part in an opera or concert: each is called part: as the part of Hamlet, in a play, of Mandane, in an opera; the first violin, tenor, or violoncello part needs no other distinction than the name of the character, or instrument.

ROLLE, in *Geography*, a town of Switzerland, and capital of a lordship, situated on the N.W. side of the lake of Geneva; 14 miles S.W. of Lausanne.

ROLLER. See ROLL.

ROLLER, in *Gunnery*, a round piece of wood of about nine inches diameter, and four feet long, which serves in moving mortars from one place to another, when near. This is done by raising the fore-part of the bed so high that a roller may be laid under it; then pushing the bed forwards, and laying another in its way, and another before that, and so on, the mortar is easily moved.

ROLLER is also a small wheel placed at the foot of the hammer of a gun, or pistol-lock, in order to lessen the friction of it against the hammer or feather-spring.

ROLLER, in *Agriculture*, a well-known implement formed of wood, cast-iron, or stone, so as to turn upon its axis, and be drawn over the surface of the land by means of horses, for the purpose of reducing the lumpy or cloddy

state of tillage lands, and rendering these, as well as those of the grass kind, smooth and even. They are constructed in different ways for different purposes, and of different sizes and weights to suit different uses in husbandry. They are, however, in general distinguished into the tillage and grass kind. It has been a matter of dispute, whether rollers with large or small diameters have the advantage, in point of effect upon the land. It is probable that there may be inconveniences in both extremes. The roller should not, however, be so small as to require much loading, as by such means much time and labour are lost. A late practical writer, however, advises that in constructing heavy rollers, the workmen should be careful that they have not too great a diameter, whatever the material be of which they are formed, as the pressure is diminished where the implement is of very large size, by its resting on too much surface at once, except an addition of weight in proportion be made. By having the roller made small, when loaded to the same weight, a much greater effect will be produced, and a considerable saving of expence be made in the construction of the implement. And he recommends that all the larger sorts of rollers should have double shafts, in order that they may be drawn by two horses abreast; and such as are employed for arable lands should have a scraper attached to them. This addition, he thinks, saves much time, and prevents the driver the trouble of constantly scraping the machine, especially in wet seasons, and clayey tenacious lands. Strong frames are also necessary for rollers, so that proper weights may be put upon them; and open boxes or carts placed upon them may sometimes be requisite, in order to contain any additional weight that may be thought proper, as well as to receive stones or other matters that may be picked up from the ground. Pieces of wood or stone, as heavy as a man can lift, are the most suitable substances for loading these implements with, where they have not the advantage of boxes for the purpose of containing such weighty substances.

There has been much inconvenience experienced in the use of this sort of implement in turning at the ends of ridges, fields, or other places, from their not moving upon their axes, but being drawn along the surface of the ground, by which they are liable to tear it up, and make deep holes and depressions before they come again into the direct line of draught, and are not brought round without great exertion in the teams: it has therefore been attempted, in order to obviate these inconveniences, to construct rollers in two pieces, and by the division in the middle to enable the different parts to twist round on their proper axes, one forward and the other in a retrograde direction. When formed in this way, the cylinders are best made of cast-iron, as they turn with greater ease and readiness.

ROLLER, *Common*. This is a sort of roller which is employed for the common purposes of tillage, and which is mostly used for rolling wheat in the spring, and grass-seeds; they are generally about five or six feet long, and from fifteen to thirty inches in diameter; but those employed for flattening one-bout ridges, in order to prepare them for drilling turnips upon, are commonly shorter and of much less diameter, and frequently attached to the drilling implement.

But of the various kinds of these rollers that are made use of, Mr. Morley of Newark thinks that those of the best construction, and which answer the most perfectly in practice, are such as are made of cast-iron, and divided into two parts: the length from three feet to three feet six inches, covering a surface of from six to seven feet, and being above ten hundred weight; the frame should be made

in a stout manner, with shafts for one horse, to be fixed on the near side, and hooks put in on the other side in order to have recourse to an additional horse when it may be necessary. The gudgeons or pivots should act upon small case-hardened friction-wheels, two to be fixed upon each side the frame; with a small roller made of hard wood, about nine inches long and three inches in diameter, bound at each end with iron, and to be fixed to the back part of the frame, so that both rollers may act with each other in the centre wheel, which will be a means of keeping the great roller steady, and at the same time very much diminish the draught of the implement.

And it is observed in the Agricultural Report of Norfolk, that Mr. Priest of Belfhorpe uses a roller that is divided in two parts, rising and falling in the centre, for the purpose of rolling the slopes of ridges. And that the same useful tool is in practice in Suffolk by the Rev. Mr. Hill.

In Denzey and Rochford hundreds, in the county of Essex, where the wire-worm has long been so very destructive to the grain crops, an extremely heavy stone roller is a common implement on every farm; they are made six or seven feet long, and eighteen inches, and some more, in diameter, weighing from one and a half to two tons.

In Devonshire they use heavy granite and moor-stone rollers with two horses, which are from five to eight feet in length, and of proportionate diameters, for rolling wheat and pasture grounds, as well as for aiding the operation of separating the spire from the mould on the burn-beat-lands, in preparation for the former crop and turnips.

In many other districts heavy stone rollers, of the free-stone and other kinds, are preferred to all other sorts for tillage uses.

**ROLLER, Compound.** This is an implement of the roller kind, constituted of the plane or common and spike kinds united in the same frame; but it is capable of being used separately, and its weight varied according to the nature or circumstances of the land. It is the ingenious invention of Mr. Amos of Lincolnshire, in which the spike part of the roller is made of a piece of oak wood, seven feet long, and fifteen inches and a quarter in diameter, hooped with iron at each end. The inventor advises in constructing it to divide the circumference of this roller into twelve equal parts, from which to draw parallel lines, one division oblique the whole length of the roller. On the first of these lines to set off two inches at each end, and divide the remainder into twenty equal parts, of four inches each. On the second line to set off four inches at each end, and divide the remainder into nineteen equal parts; and so of all the other lines alternately. In every division to fix an iron spike, so that there will be twenty spikes in one row, and nineteen in the other, throughout the whole circumference, making in all two hundred and thirty-four spikes. That part of the spike which projects out of the wood is four inches long, one inch square at the circumference of the roller, and three-quarters of an inch square at the point. The tongue, which goes into the wood, is four inches long, seven-eighths of an inch square at the circumference of the roller, and tapers to a point at the end. The plain roller is made of a piece of oak wood, seven feet long and eighteen inches diameter. In the centre of each end of both rollers are fixed iron bushes of two inches diameter. The bow part of the left-hand side of the frame is made of iron, four inches broad, half an inch thick, and is a segment of a circle twenty-seven and a half inches radius, fixed for turning the roller upside down. The string part of the bow is five feet two inches long, and eight by three inches square, made of oak wood. In these pieces are fixed gudgeons of two inches diameter, on which

the rollers move, and at four feet one and a half inch asunder. The four shafts are eleven feet long, six by three and a half inches square at the hinder ends, through which the centre-bolt passes. There are four bars four by one and a half inches square, and three and a half feet long, for bracing the shafts together. And two bars eight feet long, and three by eight inches square, with double tenons at each end, for bracing the outside frames together. In the outer ends of these tenons are linchpins for the convenience of taking the machine to pieces. The centre-bolt is made of hammered iron, two and a quarter inches diameter; at one end is a round head, at the other a linchpin. The principal use of this bolt is to give the uppermost roller inclination forward when working, and the degree of inclination is governed by the breadth of, and the distance between the two braces, which rest upon the shafts when the roller is at work, so as to make the horses carry a little weight on their backs, otherwise it would be in danger of endeavouring to fall backward. The distance between them is twelve or six inches from the centre-bolt. This implement is found of vast use in reducing the stubborn sorts of soil to a fine state of mould, or what is termed tilth by farmers. The ingenious inventor remarks, that it affords the farmer a command over dry seasons, and enables him to sow his spring and fallow crops in proper time. It likewise, he thinks, furnishes him with the means of cleaning his tillage lands from weeds, whether the root or seed kind. After passing this sort of roller two or three times over the land, with drag harrowing in the intervals, he supposes it would be rendered sufficiently fine for any purpose that it may be wanted for. And that when the cloddy surface is reduced to such a condition as to be incapable of being longer acted upon by the spike roller, the plane roller may be had recourse to with the dry harrow. It is likewise stated to be of great advantage in reitoring such grass-lands as have the sward in a degenerated state. See ROLLING.

**ROLLER, Concave.** The belying or furrow-rollers have been in common use some length of time, in most tillage parts of the country; but the concave ones have perhaps never yet been met with, except about Bradwell, in the county of Essex. They are there made the smallest in the middle, swelling out to a large circumference at each end. The whole of the farmers thereabouts highly approve of this kind of roller, having very generally adopted it. It is made of such lengths as to suit the differences of the ridges or flitches, which are made use of in cultivating the ground. And it has a scraper attached to it, for taking away the cloggy mould that hangs upon it. The most usual length of the roller part is seven feet two inches; to the extremities or outsidcs of the frame, seven feet nine inches; the length of the ends of the frame, four feet three inches; the diameter of the roller at the ends, one foot ten inches; in the concave part in the middle, one foot four inches; the circumference in the same place, four feet. A representation of it may be seen in the first volume of the Agricultural Report of Essex.

**ROLLER, Drill.** This is a roller originally contrived for the purpose of forming drills in dry light soils, for putting the grain in; but which is likewise found useful in reducing cloddy rough tillage land into a state of pulverization and fineness. The invention of it has by some been ascribed to the Norfolk farmers; but the writer of the Agricultural Survey of that district says, that he has at different periods made many inquiries for the inventor of this tool, but could not ascertain it thirteen years ago. Mr. Sillis, of Hartford Bridge, near Norwich, was mentioned to him as a person who had improved it. It is described as a cylinder of iron,

about

about seven feet in length, around which are fixed cutting wheels of cast-iron, that each turn independently of the others around the common cylinder, weighing from a ton to a ton and a half, being drawn by four horses, and is heavy work. It is observed, that the cutting wheels, being moveable, may be fixed by washers at any distance, commonly at four inches. By passing over a fresh ploughed layer, the soil is cut into little channels, four inches asunder; the seed is then sown broad-cast, and the land bush-harrowed in the direction of the drills: thus the seed is deposited at an equal depth. George, earl of Orford, gave the writer one, but the soil was too heavy for it: for breaking clods in a dry season, no tool he ever beheld comes near to it. It is supposed by some, that the main object of the practice is to save the trouble and expence of dibbling, though it is not near so good a practice.

And it is remarked by the author of the above Agricultural Report, that they are much in use in Lodden hundred. Mr. Burton, of Langley, puts in a great deal of corn thus, and approves the method so much, that hitherto he has drilled little; but thinks dibbling a vast improvement. It is, however, added, that the implement was more commonly used in the county ten or twelve years ago than it is at present; for the drill machine has been adopted by many, who formerly had a good opinion of this tool. It must, however, be found beneficial in its original intention, in many cases, on the very light friable soils; and as a pulverizing machine on those of the heavy kind, when used in suitable seasons.

**ROLLER, Furrow.** This is a tool of the roller kind, contrived for the purpose of rolling the furrows in steep hilly situations, and other places where the common sort cannot be employed. It is the invention of Mr. Pinchard, and is an useful contrivance for the purpose for which it was intended.

**ROLLER, Grass.** This is a heavy sort of roller, made use of for the purpose of rendering the surface of grass-lands smooth and even. It has been suggested, that the wooden rollers of this sort, which are frequently employed with great propriety on grass and pasture lands, are in many cases made too large to produce that powerful effect which is wanted, without the aid of additional weight being given. If made less, and well loaded, it is supposed that a greater degree of pressure will be afforded. A medium size is probably the most effectual in giving the requisite pressure in such cases. A powerful implement of this sort, which is used in the best grass district of the kingdom, weighs something less than half a ton. It is, however, made of wood; but iron or stone, where they can be had, are much better materials. It is stated in the Norfolk Agricultural Report, that Mr. Coke has the most powerful roller for grass-land that the writer has seen: it was cast at the Carron foundry. It is five feet six inches high, and five feet six inches long; weighs three and a half tons; is drawn by four horses, and cost sixty pounds. It is observed, that it leaves the surface of grass-lands in the order that it ought always to be in.

**ROLLER, Jointed,** such a one as is made with a joint or joints, in order to conform to the nature of the ridges. These kinds of rollers are constructed by some farmers in the county of Essex. Mr. Tweed has invented one, which he finds of very great use. He rolls all his clover-land for drilling wheat with it, and employs it for whatever sort of tillage-rolling is to be performed. The great object of it is to prevent the horses from poaching, by their going only in the furrow, two of them at length.

**ROLLER, Spike.** This sort of roller is constructed much

in the same way as those of the common kind, only instead of being plain, it is studded or set with a considerable number of spikes, by which it is supposed to break the soil more effectually. It is mostly employed on the heavy, stiff, lumpy tillage lands, for the purpose of reducing and bringing these into a better state of pulverization. In some cases it may be a good implement: it may be connected with the compound roller. When the drill-roller is in use, this sort of roller is unnecessary.

**ROLLER, in Gardening,** a very useful implement in many different intentions, and for several different purposes. The kinds which are most commonly employed in this way are those of stone and cast-iron, for compressing the more hard surfaces; and those of the smaller wood sort, for removing worm-casts and other protuberances on short grass-lawns, and other descriptions of pleasure-grounds, in the state of turf or sward. They are never required to be of any great weight for these uses, but to be capable of being readily managed by the labourer without difficulty or inconvenience.

No unusual peculiarity of form is here ever necessary, as the main object is constantly that of rendering the surfaces, over which they may pass, as smooth and even as possible.

Moderate or middle-sized common cast-iron rollers are now most usually made use of, for the purposes of gardening.

**ROLLER, in Inland Navigation,** a term applied to an inclined plane, with rollers on it.

**ROLLER, in Ornithology,** the common name of a bird of the mag-pie kind, called *garrulus argentoratenfis* by authors, and suspected to be the same with the bird described by Gesner, under the name of the *blue crow*, *cornix carulea*, and by Aldrovand under the name of *pica marina*. It is the *CORACIAS Garrula* of Linnæus; which see.

**ROLLER** is also the name by which some call the *ampelis*, or *garrulus Bohemicus*. This, in the Linnæan system, is a species of the *ampelis*. See **GARRULUS**.

**ROLLER, in Block-making,** a cylindrical pin turning on its own axis, which is used in some blocks, instead of a sheave.

**ROLLERS, Cylindrical,** pieces of timber, revolving on an iron axis, and so fixed above the deck, either perpendicularly or horizontally, as to prevent the chafing of the messenger or cable against the jeer and top-laid-sheer bits, &c. Those fixed forward in the manger are to facilitate the messenger to the capstan.

**ROLLERS, Friction,** are made of two parallel circular plates of brass, about a quarter of an inch thick. Four or more solid brass cylinders are placed at equal distances round these plates, and work upon their own axes, between them, at right angles. Thus any pin working through these plates of brass must touch the rolling surfaces of the solid brass cylinders, by which the friction is considerably lessened.

**ROLLER, in Surgery,** a long and broad ligature, usually of linen cloth, used for binding, surrounding, and containing, the parts of the human body, and keeping them in, or disposing them, to a state of health.

A roller consists of two parts; the *body*, and the two extremities, which some call *heads* or *chiefs*, and others *tails*. There are single-headed rollers, that is, such as are rolled at one head only, double-headed rollers, &c.

Again: some are equally rolled and gathered together; as those applied to fractures and dislocated joints. Others are cut into several chiefs or heads; as those for the head, chin, &c. Others are composed of several swaths, gathered and stitched together; as those for the tellices, &c. Some again

again are broad; as those for the breast, belly, &c. Others narrow; as those for lips, fingers, &c.

Guidon directs the roller for the shoulder to be six fingers broad; that for the thigh, five; for the leg, four; for the arm, three; and the finger, one. See **BANDAGE**.

**ROLLFELD**, in *Geography*, a town of Germany, on the Maine; 2 miles S. of Clingenberg.

**ROLLI**, **PAOLO**, in *Biography*, a Roman poet, born in 1687, the son of an architect. He was a disciple of the celebrated Gravina, who inspired him with the love of poetry and literature. The earl of Burlington having brought him to England, which he commemorates in the dedication of his opera of "Astarte" to his noble patron, who attached him to the court as master of the Tuscan language to the princesses.

Rolli did not spend an inactive life in England; for, besides being opera poet to the Royal Academy of Music till it was broke up, teaching his language to the royal family, and many of the first nobility, he published Italian odes, songs, elegies, endeca syllaba in the manner of Catullus, which were much admired. Besides these he published epigrams, and fine editions in London of the Satires of Ariosto, the complete works of Berni, Varchi, &c. 2 vols. 8vo. much esteemed; the Decamerone of Boccaccio, the Lucretius of Marchetti, Odes of Anacreon, and a translation of Milton's Paradise Lost, in Italian verse, folio.

Upon the death of queen Caroline, his royal protectress, in 1737, he left England, and returned into Italy, where he died in 1767, leaving behind him a very curious cabinet, and a rich library of well-chosen books.

**ROLLIN**, **CHARLES**, an eloquent writer and professor, was born at Paris in 1661. He was intended for the same trade as that of his father, namely, a cutler; but a Benedictine, who had watched the opening of his mind, and clearly perceived in him a genius for learning, procured for him an exhibition at the college of Pleffis; and he was immediately taken under the protection of the principal, M. Charles Gobinet. He went through, with much applause, a course of classics and philosophy; and then studied theology for three years at the Sorbonne. A way seemed now open to him in the college of Pleffis, and in 1683 Rollin entered that seat of learning. In 1687 he was made professor of rhetoric, and in 1688 he obtained the chair of eloquence in the Royal College. He became rector in 1694, and occupied that post two years. During his administration, he revived the study of the Greek, substituted academical exercises for the representation of tragedies, and introduced the custom of obliging the scholars to get the holy scriptures by heart. In 1698 he was appointed coadjutor of the college of Beauvais, an office which he held till 1712. In the year 1720 he was again rector of the university; after which he entirely devoted himself to the composition of the works for which his name is particularly celebrated, and of which the following is an enumeration of the principal: "Traité de la Manière d'enseigner et d'étudier les Belles Lettres par Rapport, à l'Esprit et au Cœur," 4 vols. 12mo., published at different times between the years 1726-8, with a supplement relative to the studies of children, and the education of females. Several editions of this work have been published. "L'Histoire Ancienne des Egyptiens, des Carthaginois, des Assyriens, des Babyloniens," &c. 13 vols. 12mo., published between 1730-38. Voltaire speaks in terms of high respect of this work: while he admits that the latter volumes are not written with so much care as the earlier ones, yet he says it is the best historical compilation in any language; because the compilers of such works are seldom eloquent, which Rollin always was. It has been

thought, and with probability, that Rollin wrote history chiefly for the opportunity of throwing into the narrative abundance of useful reflections. He paid too much credit to the exaggerations of the ancient historians, and is in a good measure void of that critical sagacity, which should be characteristic of the writer of history. This quality could scarcely be expected from the man who gave implicit creed to the miracles, as they were called, of the abbé de Paris, and who was accustomed to pray kneeling before his tomb. The other principal work of Rollin was "Histoire Romaine depuis la Fondation de Rome jusqu'à la Bataille d'Actium," 8 vols. 12mo. This was continued by Crevier to the reign of Constantine. Rollin died with a character universally esteemed, at the age of 80, in the year 1741. His writings have been popular both in France and in other countries. Voltaire says, that he was the first member of the university who wrote with purity and dignity. He began with establishing his reputation as a classical scholar, by a number of Latin harangues and poems, which have been printed; and by an edition of Quinctilian, intended for the use of schools, which he illustrated with short notes, and a preface. This edition of Quinctilian has been several times reprinted, in 2 vols. 12mo.; that in our possession was published at Paris in 1774.

**ROLLING**, **ROTATION**, in *Mechanics*, a kind of circular motion, in which the moveable turns round its own axis, or centre, and continually applies new parts of its surface to the body it moves upon.

Such is that of a wheel, a sphere, or the like. Such, particularly, are the motions of the earth, the planets, &c.

The motion of rolling is opposed to that of *sliding*; in which the same surface is continually applied to the plane it moves along.

It must be noted, that in a wheel it is only the circumference that properly rolls; the rest proceeds in a compound angular kind of motion, and partly rolls, partly slides. The not distinguishing between which two, occasioned the difficulty of that celebrated problem, the *rota Aristotelica*, *Aristotle's wheel*.

The friction of a body in rolling, or the resistance made to it by the roughness of the plane it moves on, is found to be much less than the friction in sliding.

Hence, the great use of wheels, rolls, &c. in machines; as much of the action as possible being laid thereon, to make the resistance the lesser.

For the laws of bodies rolling on inclined planes, see *Inclined PLANE* and *DESCENT*. See also *ROTATION*.

**ROLLING**, in *Gardening*, the work of rendering any surface level by means of the roller. It is practised equally for the purpose of bringing the surfaces of the gravel and other kinds of hard walks and roads into an exact and even order, as well as those of pleasure-grounds, which are in the condition of short or mown grass. And it is sometimes applicable in other intentions, as those of rolling in particular sorts of seeds, instead of putting them in by means of treading the beds by the feet, and the rolling down and rendering more close the too loose and open grounds of gardens, &c.

The rolling down of garden-walks and roads should always be done, when possible, immediately after slight falls of rain, the gravel or other kinds of materials being previously put in suitable order by sweeping and raking with proper rakes for the purpose. The roller is then to be carefully drawn up on one side and down the other of them as close as possible to the grass verges, and afterwards along the middle parts, in a forward and backward direction, which mostly completes the work.

## ROLLING.

In rolling and rendering short-grass pleasure-grounds smooth and even, it is usual to go over them, in the first place, when they are to be mown, as soon as possible after a good fall of rain, with a small wooden roller, in order to take up and remove the worm-casts, and then to follow with the iron one, beginning at one side and going on in a regular manner over the whole, in a close up-and-down direction. The rolling, in these cases, is sometimes also performed for the purpose of mowing only, which is always done by the wooden roller, as it clears the grass in the best manner; the iron roller being run over afterwards, when the mown grass has been removed.

Rolling should be frequently practised in cases of this nature, in order that the walks, roads, and lawns, may be kept in a neat, proper condition, and never be suffered to run into a ruinous and disorderly state.

ROLLING, in *Husbandry*, the action or operation of drawing a roller over the surface of the ground, with the view of breaking down the clods, rendering it more compact, and bringing it even and level; or for only levelling the surface, as in grass-lands. This is a practice that becomes necessary both upon the tillage and grass-lands, and which is of much utility in both sorts of husbandry. In the former case, it is made use of with different intentions, as for the purpose of breaking down and reducing the cloddy and lumpy parts of the soil in preparing it for the reception of crops. It is also of great use in many cases of light soils, in rendering the surface more firm, even, and solid, after the seed is put in. It is likewise found beneficial to the young crops in the early spring, in various instances. And it is stated by the author of *Practical Agriculture*, that in the cases of stiff, heavy, and adhesive soils of different kinds, it may frequently be made use of with the first-mentioned intention with very great advantage; but it should only be employed when such lands are tolerably dry, for when drawn over the ground under the contrary circumstances, little benefit can be afforded in the way of pulverization, while much mischief must be produced by the poaching of the horses, and the plattering the earth round the implement. But by using it in the manner just directed, all the lumpy or cloddy parts of the surface soil may be effectually crushed and reduced into a fine powdery state, fit for the reception of the seed. And that if, in such sorts of soil, it be applied, in the intervals between the different harrowings, it may contribute much in the same way, not merely by reducing a great number of the lumps by the pressure that it causes, but by forcing others so much into the ground that they may be acted upon, and further broken down by the fermentation that mostly takes place in the soil after the land has been stirred. In all the light and more porous sorts of soil very beneficial consequences may also be derived from this operation by the consolidation of surface that is thus produced, and the more perfect retention of moisture, by which the seed, especially if of the small kind, is enabled to vegetate more equally, as well as in a more expeditious manner than would otherwise be the case. It is likewise supposed, that, in cases where lands have been left rough after ploughing, for the purpose of more effectually destroying weeds, it may be of utility, by being employed before the harrows, to give them more power in laying hold of and reducing the soil, and by the pulverization that it affords, and the more perfect retention of moisture that it causes, in consequence of the surface being rendered more close and compact, the seed-weeds are produced more abundantly, and more readily destroyed. It is likewise in these last methods, Mr. Donaldson says, that it proves to highly beneficial in all cases where grass-seeds are sown; as well as by the equality and smoothness of surface

that are thereby produced; and it is well observed by the same writer, that if no other benefit were derived from rolling lands in tillage, than smoothing the surface, even that in harvest is of material consequence, more especially where the crops are cut down with the scythe, which is general in most of the southern districts of the kingdom, and which the increasing scarcity of labourers must soon, in all probability, introduce into those of the north. It is also remarked by Mr. Morley, in the fourth volume of *Communications to the Board of Agriculture*, that old sward, or grass-feeds, upon first breaking up, should always be rolled before dibbling for either wheat, beans, or pease, as it makes the land more solid, and the grain, when it vegetates, will form a stronger root. Wheat should always be rolled in the spring after frost, as it will make the soil adhere more closely to the roots of the plants, which very much encourages vegetation, and will cause the stem to be much stronger, and the grain will be brought to greater perfection. Barley and oats should always be rolled when the blades are about an inch above the ground, if the weather permits; and turnips should be rolled at night, soon after the plants make their appearance, which will be a means of destroying a great number of slugs and snails, that are very destructive to the young plants. And it is supposed by Mr. Somerville, in his *Agricultural Survey of East Lothian*, that rolling, when conducted in a judicious manner, is highly beneficial, and admits of being much extended, especially upon all winter crops after that season has been severe, and without any regard to soils, as both loams and clays, after much naked frost, have their cohesion so much broken as to leave the plants quite loose, and almost without any establishment. It has also been stated, that the rolling of wheat, rye, barley, &c. with a roller of good length, and half the weight of the common ones above described, may be advantageous in other ways, as it presses down the soil that has been raised by the frosts about the minute ramifications of the attracting vessels or ducts, and augments the quantity of mould upon them by breaking the little lumps of sod; which, indeed, were very serviceable in winter by affording shelter, but in spring will still be of greater use, by such imminution in filling up the fissures, and preventing, in a great measure, the ill effects droughts have on light soils, by retaining and filtering rain-water; whereby the soil imbibes whatever is nutritive, and what is superfluous of the simple fluid only escapes.

But it is added, that although these are some of the many advantages rolling produces in agriculture, notwithstanding it amounts to no more than mere conjecture, that, in general, rolling corn may do more damage than it can good, if such cautions as the following be not carefully attended to; *viz.* never to roll corn but in dry fresh weather; by no means to use heavy rollers, nor to roll too early, as before the blades be pretty strong, for the wounds that the blades may receive, the roots, being then tender, will be unable ever to recover; nor too late, as, when the stalks are hardened and grown to any height, for the roller will break them, which injury can hardly be repaired, and the crop is thereby greatly hurt: that none but light lands are proper to be rolled with this view, and those which have been manured that or the preceding year with dung only: in short, none but rich, light soils, in general, can be improved by rolling in this intention; for in poor lands it opposes the most active principles, and undoes all that has been done for the crop by ploughing, &c. It is consequently concluded, that the soil, the condition, the growth of the corn, the weather, and the weight of the roller, are all to be most scrupulously regarded: when all coincide, the advantages of rolling may be great; but when they do not,

## ROLLING.

the disadvantages may be insuperable. Rolling, then, is neither the least critical, nor the most insignificant piece of the husbandman's profession; therefore ought not to be performed at random and without circumspection, in cases where young crops are concerned.

Mr. Marshall, in his *Rural Economy of Norfolk*, in speaking of rolling, remarks, that one circumstance requires to be mentioned, which is, that the roller, notwithstanding the lightness of the foil, and its proneness to be injured by dry weather, is never used in Norfolk for the purpose of compression. He never saw one used by a farmer either upon fallow or upon a lay; not even upon the first year of a clover-lay, to smooth the surface for the scythe. The only uses to which he has seen a roller put, in that district, are that of smoothing the surface before sowing, to prevent the seed from running down too low, and that of smoothing it afterwards as a preparation for the scythe; and even this operation is performed with a roller not more perhaps than seven or eight inches in diameter; a circumstance which he confesses he is no way able to account for; nevertheless, it would be rashness to condemn an established practice, unless he could, from his own experience, or from adequate observation on the experience of others, prove it to be ineligible. And it is stated, that there is a sort of land which, when clover is sown upon it, throws out the young plants after a frost. Rolling in the beginning of winter, and immediately after the frost is gone, will, in some measure, prevent this. The first rolling hinders the frost from penetrating so deep as it would otherwise do; and the second makes the land firm, after having been loosened by the change from frost to open weather. In the latter case, or that of grass-land, this is also a process that is of much advantage, especially where such lands are kept under the scythe. And it is probable, that in many cases of pasture lands it may be found of great benefit. In the former it is found beneficial in keeping the surface free from hills, and in a more even state, as well as the grass from becoming in so tusk-like a condition, as is often the case where the practice is neglected, or not well understood. And in the latter it may perhaps have a similar effect, and keep the grass more free from tufts, and in a more regular condition, which is a circumstance of great consequence in the practice of grazing. It has been remarked, that the impression of the roller not only renders the surface more level and fine, but at the same time induces the grass plants to spread more laterally, and in that way to form a better and more close sward, which may be highly beneficial in both cases. Its importance on new laid-down grass-lands is therefore extremely obvious, as it must be highly serviceable in these different intentions. And the worm-casts are by this means reduced and brought into order, by which means the mowing can be performed with greater facility, and in a closer manner. Besides, it may be useful in other views, as by pressing the mould, as well as the manure, more closely round the roots of the grass plants; and in consequence of such means, they may not only be better established in the soil, and their vigorous growth more effectually promoted, but, from the moisture being more fully preserved in the ground, be in less danger of injury from the effects of heat in the summer months, and of course better crops be afforded at the period of cutting them down. In order to perform this business in the most complete and effectual manner, a roller of considerable weight is necessary, such as has been already described; and it has been advised, in order to prevent as much as possible the ground from being injured by the feet of the animals that draw it, as may frequently be the case where they follow each other in the same part, it may be the best practice to

have them yoked double, as by that means there will be less treading on the same portion of the surface; and that where two horses are sufficient to execute the work, more should never be made use of; but if a third should be found necessary, it may be attached as a leader in the middle, before the other two: a greater number of horses can seldom or ever be of any material advantage in this sort of work. It is also suggested as necessary, to be very careful in executing this operation, to see that every part receives the due impression of the implement. On lands where this sort of work is regularly performed, it will seldom be requisite to pass more than once in a place, but in other cases it may often be done more frequently with benefit; and in particular cases, a more frequent repetition of the operation is absolutely requisite, in order to bring the ground into a proper state. It is necessary, in the execution of this business on grass-lands, to attend in a particular manner to the season, as it cannot be performed with advantage, either when the surface is in too dry or too moist a condition. It is stated, that in these cases the work of rolling may be advantageously performed at different seasons, as in the beginning of the autumn, and in the commencement of the year, or very early spring months; but the latter is the most common period. But in order to its being executed with the greatest possible benefit, a time should always be chosen, if possible, when the ground is in a suitable state for receiving the impression of the implement. In the drier descriptions of land it may frequently be performed in the most beneficial manner, after the land has been rendered a little soft by a moderate fall of rain; but in those of the contrary sort, it may be necessary to wait till the superabundant moisture be so much dried up, as to admit the animals employed in drawing the machine, without poaching or otherwise injuring the surface of the ground while the process is going on. It has been remarked by Mr. Boswell, that the rolling of watered meadows should be executed towards the latter end of February or beginning of the following month, after the land has been left in a dry state for a week or ten days. And that the work should be performed lengthwise of the panes, going up one side of the trenches, and down the other. And in the case of rolling the common hay lands, it is a good mode to proceed up one side the field, and down the other, somewhat in a similar manner, as by that means the work may be the most completely executed, and with the least trouble.

Also a writer, in the *Communications to the Board of Agriculture*, mentioned above, has remarked, that sward and meadow land should always be rolled in April or the beginning of May, and when the ground is in a moist state, as it causes the grass to be of a more kind nature, and reduces the hills raised by the ants to a proper state of being mown over.

Likewise on such new grass-lands as have been just restored to the state of sward, and which are often thin and patchy, when seeds are sown over such parts, the roller may frequently be run over them in order to force in the seeds; but a better practice is to turn sheep upon the lands, confining them upon such patches by means of hurdles, in order that they may tread them in. In either case, a rather moist time should be chosen for the purpose. In cases of this nature, where there is a degenerate sward, Mr. Amos, in his *Minutes on Agriculture*, advises the use of his compound roller, which should be run over the ground early in March, when the sward will admit the spikes without being injured by the feet of the horses, the land being previously covered with well-rotted dung, or compost, in the proportion of from about eight or ten tons to the acre. It should be well rolled in different

different directions, till the surface sward is pretty much broken, then sowing the grass-seed over the land, and after letting it be well dressed with the sward-dresser, and all the rubbish collected cleared away, rolling it well down with the plain roller, and admitting no sort of live-stock afterwards upon it. In this method of using the roller, vast improvements may, in many cases of degenerated or worn-out grass-lands, be effected, without incurring any very heavy expenses, or much trouble. See *Sward-Dresser*.

*ROLLING-Bridge* signifies, among *Canal-Makers*, an *INCLINED Plane*; which see.

*ROLLING-Carts*. See *CARTS*.

*ROLLING-Mill*, in *Metallurgy*, and particularly in the *Iron Manufacture*, is a mill for reducing masses of iron or other metals into even parallel bars, or flat thin plates: this is effected by passing the metal, whilst red-hot, between two cylindrical rollers of iron or steel, which are put in motion by the power of the mill; and being so mounted in a strong metal frame, that they cannot recede from each other, they compress the metal which is passed between them, and reduce it to a thickness equal to the space between their surfaces.

It requires a most enormous power to put in motion the rollers which are employed for laminating iron in the large way; and for this reason, the greatest number of rolling-mills are situated upon the banks of rivers which have the advantage of a sufficient fall to turn the machinery. Of late years, the improvements of steam-engines have been carried to such a high perfection, as to put them on a par with water, for most purposes, and particularly for rolling-mills, as the waste heat of the furnaces used for heating the metal may be employed, in part, to raise steam for the engines which turn the rollers.

Rolling-mills were not very generally used in the iron manufacture till within these sixty years. The old mills which were first used are extremely simple; two separate water-wheels are placed on the opposite sides of the mill, with their axles in the same direction, but at different heights, so that one wheel can be connected with the upper, and the other with the lower roller: it therefore requires the two wheels to have the water delivered at opposite sides, to make them revolve in different directions, in order that the upper surface of the lower roller, and the under surface of the upper roller, may move in the same direction, and pass the iron between them. The construction of the rollers generally used in such mills is shewn at *figs. 3, 5, and 6, of Plate V. Iron Manufacture*, except that the two rollers, F and G, are there shewn with equal pinions, *d* and *e*, fixed upon the ends of their pivots, to compel the two to revolve equally together; whereas, in the mills with two separate wheels, no provision is made to ensure the equal motion of the two. The gudgeons, or necks, of the lower roller, G, are supported in brasses, fitted into strong carriages of iron E, E, which have holes through their ends, to receive four strong iron bolts, A A, B B; these stand perpendicular, and form the frame, to retain the rollers at the proper distance, being fitted through the carriages E with heads below, so that they cannot draw out. The upper ends of the bolts are cut with screws, upon which nuts, *a, a*, are fitted; and these being turned round by iron handles or wrenches, screw down the pieces D, D, and advance the rollers nearer together; or, by a contrary motion, increase the distance between them; *5 (fig. 6)* is a strong iron bar, extended from one bolt, A, to the other, B, and fixed fast; it supports an iron plate, forming a kind of table before the rollers, to guide the iron through them. The rollers have square heads upon the ends of their gudgeons; and upon these squares, large cast-iron

sockets or boxes, as L, are fitted, and these, at the other ends, are fitted upon similar squares on the ends of the water-wheel axis. A little play or looseness is admitted in all these squares, because the upper roller is set at different heights, according to the thickness of the work which is to be rolled between them: this play is required to allow the rollers to move freely, when they are not exactly in the line of the water-wheel axis: it is to accommodate this circumstance that the principal care is required in constructing a rolling-mill. Our readers will gain a good idea of the best proportions of a mill, with two independent water-wheels, from the following directions for building one in Northumberland, which were given by Mr. Smeaton near 40 years ago. The two water-wheels are to be under-shot, and of different sizes, *viz.* 15 ft. 4 in. and 14 ft. 5 in., the mean diameter being 15 ft. The breadths in their float-boards are to be three feet each, the small wheel being laid lower than the other by seven inches: this, with the difference of their diameters, will make the centre of the large wheel 11 inches higher than the other. The different heights of the crowns of the falls or breasts, down which the water descends to act upon the wheels, and the positions of the water-shuttles, are to be so adjusted, that the gates or shuttles being equally drawn up by their flarts, the wheels will, as near as possible, revolve in equal times, and with equal power. The rings of the water-wheels are to be made of cast iron, that their weight may act as flies: the ring of the lesser wheel is to be made six inches in thickness by six inches deep, while that of the larger is to be only five by six. The greater quantity of matter in the lesser wheel, therefore, will give it nearly the same momentum as the larger wheel.

The rings of the water-wheels are each to be formed by eight pieces or fellies, the exterior circle of the greater wheel being thirteen feet diameter, and that of the less twelve feet four inches: the length of the fellies is to be about half an inch shorter than their true length, in order to admit an oak wedge of one inch thick to be introduced into every joint after the rings are screwed together by the joint-plates of wrought iron, which unite the fellies. These plates are to lay upon the plain surface of the felly, and not to be let in as the common wooden rings of water-wheels, in order that the oak wedges may completely fill the joints at the ends of the fellies. The wheels are to have wooden arms, and it must be observed, that the mortises through each of the iron fellies, for receiving the ends of the arms of the wheels, are to be about two inches and a half in width, and that they are to be a little dove-tailed, in their length only, so that the mortises being longer on the outside of the ring, and the wood of the arm being spread into them with wedges, will produce firm ties to the centre; but as a farther security, pins are to be put in after the wedging is completed. The mortises in the rings for the flarts, which support the float-boards, are to be four inches by two, without dove-tailing, or rather they should be larger outside than inside. The breast or float-boards will fix by nails into the joints and arms, where they fall; but that the breast-boards for the intermediate floats may also have a fastening, holes of about one inch diameter, and about four inches deep, must be cast in the ring, at the places for every other float; these holes, being filled up with pieces of oak, will afford places to drive the nails for securing the boards. The axles of the water-wheel are to be of cast-iron, with flanches to screw the arms of the wheel against. The total length of each axis is to be seven feet one inch, and the diameter throughout the axis is to be a circle of nine inches. The manner of fixing the arms upon flanches is to be found in *Plate XXXIV. Mechanics*, in our article *MILL*.

## ROLLING-MILL.

The brasses upon which the necks of the water-wheel axles are supported, are intended to be let into cast-iron stocks, which are again supported upon wooden bed-planks, and those upon the cap-stones of the walls, which (under these at least) are supposed to reach all across the thickness of the walls, those necks being first truly and smoothly turned; at each end, beyond the neck, is formed an astragal or moulding, to keep the wheel in its place from moving endways. The ends of the axis are terminated by an indented head, shaped somewhat like a square citadel in fortification, and an iron box is fitted upon this to communicate the motion to the rollers, the surface lines of the indented head being formed a little rounding, that the box may not only be certain of taking its bearing in the middle, but likewise be capable of complying with the motion of the rollers: and in order to give it still more liberty, the end of the box which is farthest from the water-wheel, is formed into a square of eight inches, which is again surrounded by another box, whose external surface is round. This box is formed at the end of a round spindle or axis three feet long, and terminated at the other end with a square of eight inches, which enters one end of a square box, and at its other end receives the square of the roller, supposed to be of six inches, but may be of any other size which is thought necessary. It is to be noted, that all the squares are to be made larger than those of the rollers, in order that they may wear longer; and all the insertions are to be less than those at the end of the water-wheel axles, that the axis may not be rendered useless by the wear or failure of the citadel heads which are introduced, as they are expected to last many years; and if any thing should happen to them, the axes are made alike on both sides of the water-wheels, that they may change ends; therefore, there is nothing of consequence likely to fail by wear or breakage, except the smaller intermediate work between the axis and the roll, which is easily replaced. Holes are to be made through the boxes and joint parts for iron bolts to pass through rather loosely, so as to prevent the boxes and squares separating, but not to confine the joints from yielding to the motion of the rolls. The water-wheels are supposed to be closely adapted to their conduits, and their axes to remain immovable as to height, at the difference of eleven inches in level, while the rolls are supposed to vary in their diameter from twelve inches to nine. This will be allowed for, by the distance that the squares upon the rolls are from the end of the axis; for though the house is supposed no more than ten feet wide between the walls, the distance between the middle of the citadel heads at the end of the water-wheel axis, and the middle of the squares of the rolls respectively, is upwards of four feet; and in that length no less than four joints are introduced, every one of which complying a little, a small difference in the height of the roll will produce no sensible difference in the communication of the motion from that of a right line; all the joints being kept oiled or greased, which will be not less proper on that account than to keep the parts from wearing. In order to preserve the directions as near as possible to a right line, Mr. Smeaton proposes that the lower roll shall be placed originally half an inch below the centre of the axis which turns it: suppose the rolls were first made of twelve inches diameter, while the difference of the height of the axis is only eleven, the upper roll will be just half an inch too high, so that the compliance in each will be equal, and no more than half an inch in four feet length. Thus it appears, that when the rolls are reduced by wearing from twelve inches to eleven each, then the upper roll as well as the lower will be half an inch too low for its axis; still

neither will need to comply or vacillate more than half an inch. The roll being now of a just diameter to answer the different heights of the axis, let the lower roll be raised to its just height, and then both the rolls will work true till they are further reduced; but when they become reduced to ten inches and a half diameter, the upper roll will become half an inch too low; then raise the under roll half an inch above the line, and the upper roll will then be truly in the line; so that when the upper roll is come down to be half an inch below the line, the rolls will be reduced to ten inches; then raising the under roll a quarter of an inch more, it will be three quarters above the line, and the upper roll will be a quarter of an inch under the line; and when it comes down to three quarters below the line, the rolls will be reduced to nine inches and a half; therefore, lastly, raise the under roll another quarter, so as to be an inch above the line, and the upper roll will be reduced to half an inch below it, so that when it is come down to an inch below it, the rolls will be reduced to nine inches. In this way the departure of the rolls from a right line will never become more than half an inch, while they are reducing from twelve to ten inches; nor more than three quarters, while they are reducing from ten to nine and a half inches; at the worst they will be no more than an inch, while they are reducing from nine and a half to nine inches. The greatest inequality is purposely made at this place, both because the purchase of the wheels is then greatest and most able to overcome an addition of friction, and because the time that they will continue in this state is the least. If the axles are placed at ten and a half inches distance instead of eleven, the vacillation each way will never exceed three quarters of an inch; nor more than one inch to reduce the rolls to eight and a half diameter.

The raising of the under roll is not to be done by raising the whole of the bed of the roller-frame; this is to be set originally half an inch lower than the true line; and when the lower roll requires raising, it is to be effected by putting iron plates under the carriages of the lower roll gudgeons, so that they will stand as much higher than before, and not to make the several rises by additional plates, but to have plates of the different gages, so that each will lay in one solid piece.

Mills, on this construction, are still used in many iron-works for rolling coarse iron bars, but are unfit for any better purpose, from the difficulty of adjusting the two water-wheels to an equal velocity; and if one roller moves quicker than the other, the metal becomes more extended on that side than upon the other, and is thus rendered convex. Another defect is, the want of proper fly-wheels to regulate the mill; for the cast-iron rims to the water-wheels by no means answers the purpose of fly-wheels, unless they are made to revolve so quickly that the water loses much of its effect upon the floats. Fly-wheels are, perhaps, more useful for rolling than in any other kind of mills, because the resistance to be overcome is so variable; being at one moment very great for a large piece of iron, then smaller whilst it is passed through a second time, because the iron is to be less reduced: and in the interval of returning the iron, to put it through again, there is no other resistance than that of the friction of the machinery. Again, when the iron has been passed through several times, the resistance is greatest of all, because the metal has become harder, both by the compression it has undergone, and from being gradually cooled; also, the metal, being thinner, will not yield so readily to the pressure, as when in a larger mass. By the proper addition of a heavy fly-wheel, great advantages, in point of power, are gained, as it tends to equalize

## ROLLING-MILL.

equalize all these irregularities; and in every interval, when the resistance is removed, the water-wheel gives a rapid motion to the fly, the force of which will be returned when the work is applied: in such a mill, if the workmen have an extraordinary large piece of metal to roll, they suffer the mill to work for a few seconds without any resistance, then putting in the iron, it is carried through at once by the momentum of the fly, though requiring a power far beyond the ordinary force of the water-wheel. The most approved method of applying a fly-wheel to a rolling-mill, is to have a large cog-wheel upon the axis of the water-wheel, to give motion to a pinion, upon the axis of which a heavy iron fly-wheel is fixed: the wheel and pinion are of such a size as to make the fly revolve about three times to one of the water-wheel: at the opposite side of the great cog-wheel another pinion, of about half its size, is placed, and to the extremity of its axis produced, the rollers are connected, the two rollers being made to turn together by means of pinions upon the ends of their gudgeons, in the manner shewn at *d e*, *fig. 6. Plate V.* If more than one pair of rollers is to be worked, a cog-wheel is fixed upon the axis which turns the rollers, and works another equal wheel upon the axis of the second pair, placed parallel to the former; in this case the lengths of the two axes must be different, so that the lines in which the bars will come through the different rollers, will not interfere with each other, but leave sufficient room between for the men to work. In most common mills, rollers, such as are represented at *figs. 3, 5, 6, of Plate V.* are employed; but to these there are some objections; first, the four nuts *a, a*, cannot all be turned at once with such precision as to bring the upper roller exactly parallel to the other; the means the workmen use for this, is to have a small iron wrench, or handle, fitted upon two of the nuts, *a, a*, and these they turn round a small quantity every time the metal has passed through, in the interval whilst it is returned to be put through again. The workman who stands in front to introduce the metal between the rollers, turns the nut on his left-hand side which is nearest to him; whilst his comrade, who receives the metal, and hands it back again to him over the roller, turns the nut on the opposite corner of the frame: by this means, as only two, instead of four, of the nuts are turned, the pieces *D* are constantly put out of the horizontal position, in which alone they can take a proper bearing; also, in these frames there is no support for the weight of the upper roll; but when there is no metal beneath it, it falls down, and rests upon the other; when the metal is suddenly introduced, it lifts the roll up to its bearing with a jerk, which endangers the breaking of some of the parts, and generally causes the nuts to start a little before they settle themselves to the strain. In the modern mills, the frames for the rollers are made of cast-iron, as shewn at *figs. 1 and 2. Plate V.* The checks, *A*, are cast in one piece, and form a bed for the reception of the brads of the lower roller *H*; a piece, *C*, is fitted upon the top of the cast-iron checks, and is held down by two strong wrought-iron bolts, with nuts, *a, b*, to screw it down, and regulate the distance between the two rollers, the gudgeon of the upper roller, *G*, being confined by a brad let into the piece *C*, but to bear it up from falling: when there is no iron between the two rollers, another brad is placed beneath the gudgeon, *G*, and suspended by bolts, *d, d*, from the piece *C*; by this means the two rollers are retained always at a proper distance asunder. The two standards *A, B*, *fig. 2*, at the opposite ends of the rollers, have broad feet at bottom, by means of which they are bolted down to massive ground-hills, which extend all across the mill-house. The rollers *E* and *F* are

caused to move together equably by means of pinions *a, b*, which, that they may work well, are made with accurate teeth, of not more than  $1\frac{1}{2}$  or 2 inches pitch, or distance asunder; and, to give the requisite strength, they are made of considerable breadth, as the figure shews. Two large flat iron plates, *I* and *K*, are screwed to the two standards, both to strengthen them, and to form a table, upon which the masses to be rolled are laid to be presented to the rollers, and having passed through, are received on that at the opposite side.

The rollers shewn in *figs. 1 and 2*, have a number of grooves in them, which being opposite to each other, leave openings of a determinate figure for the purpose of rolling square bars, with the angles upwards; they do not therefore require to be adjusted in distance, as other plain rollers do, but are always, after the first erection, retained at the same distance; in this case the pinions *a* and *b* serve very well to connect the motions of two rollers together; but when the rollers are required to be adjusted during the working, as in the *Plate Rollers, fig. 6*, the pinions must necessarily have very coarse and long cogs, that they may not be so much affected by increasing or diminishing the distance between their centres; in this case they work very indifferently, and frequently break by the awkward manner in which such coarse teeth always meet each other when upon wheels or pinions of small radius, particularly when the proper distance between their centres is not preserved. As a partial remedy for this difficulty, the pinions are, in some mills, made very broad, with fine teeth, and mounted in a separate frame, exactly similar, except in its strength, to that of the rollers; this is placed at a distance of three or four feet from the rollers; then a coupling, or short shaft, being interposed between the squares at the ends of the axis of the pinions, and those of the rollers, they permit the latter to be adjusted without disturbing the pinions; and the length of the shafts will accommodate for the differences between them.

In *Plate IV. of Iron Manufacture*, we have given three figures of a very capital rolling-mill in Messrs. Walker's extensive iron-works at Rotherham, in Yorkshire, where they have several mills worked by the same river. The one in question is employed in reducing iron to small rods for nail-making, by first rolling the pieces to flat bars, and then passing them through a pair of slitting rollers, which divides each into several small square rods: it is, therefore, much smaller in its dimensions than the great mills used for rolling thick iron plate; but we have selected it on account of the arrangement of its wheels, which renders it superior to the mills in common use, as it works without the pinions of which we have spoken. *A A*, in the plan, (*fig. 1.*) is the water-wheel, 17 feet diameter, and five feet six inches broad: it is of the under-shot or rather breast-kind, the water being delivered below the centre, but confined to act upon the wheel by a breast of masonry, curved to correspond with the wheel very exactly. The pivots or gudgeons, *n*, of its axis rest on bearings, supported by the walls *N*. At one end of the axis a clutch-piece, *M*, is fixed, to give motion to a second axis *k*, which, being in the same line as that of the water-wheel, may be considered as a continuation thereof. It is carried under the floor of the mill. It has two large cog-wheels, one marked *b*, and another of the same dimensions at the opposite end, which is only seen in *fig. 2*, as it is concealed in *fig. 1*, beneath the wheel *f*, which it turns. The first of these wheels, *b*, gives motion to two wheels, *a* and *c*, which are on the axes *I* and *H*, and give motion to the lower of each of the two pair of rollers, situated in the frames at *E F* and *C D*. This wheel-work is shewn in

## ROLLING-MILL.

*fig. 3.* The wheel at the other end of the shaft, *k*, (see *fig. 2.*) turns the wheel *f*, situated directly above it; and this gives motion to two wheels, *e* and *g*, of the same dimensions as *a* and *c*. Their axles, *L* and *K*, are connected with the upper of each pair of the rollers. By the introduction of the wheel *f*, the small wheels, *e* and *g*, are made to revolve in a contrary direction to the wheels *a* and *c*; and, at the same time, the centres of the former are raised a sufficient height above the latter, to allow for the difference in height of the centres of the upper and lower rollers of each pair. The coupling-boxes, *L K* and *p p*, which unite the axles of the wheels to their respective rollers, have sufficient play in the joints to allow for that small deviation which takes place in separating the rollers, to adjust them to different thicknesses of the metal they are intended to roll; though these flanks should be represented longer than the limits of our plate have allowed, the space between the frames for the wheels being in reality eight feet, instead of five feet nine inches, as given in the drawing.

By this arrangement of the wheels of the mill, the contrary motions of the two rollers are communicated from the same water-wheel, without the intervention of small pinions, which, in works requiring such heavy trains as that of rolling iron, always work with difficulty and enormous friction; so that they break and wear out constantly, making great interruptions to the work. In the present instance, the wheels are all of considerable size, and, therefore, transmit the power more equably, at the same time that they give the two rollers precisely the same velocity, which is a circumstance of some importance in making good rolling for plates or bars, which will be irregular, if one roller turns faster than the other, in consequence of one side of the metal being more expanded. The framing of the mill (*Plate IV.*) is very clearly expressed by the drawing. The axles *H* and *I*, of the wheels *a* and *c*, are supported in bearings, screwed down to iron frames, which are securely fixed to the solid masonry. On the other side, the iron frame, *O O*, is erected to support the axles of the wheel *L K*, and also that of the wheel *f*, as shewn in *fig. 2.* The main axis *k*, and the wheels upon it, are carried under ground, and supported on the walls, as shewn by the plan. The roller-frames, *C D* and *E F*, (*fig. 1.*) are fixed down upon strong beams, extended across from the frame, *O*, to the frame on the opposite side. The position of one of these beams is shewn by dotted lines on the right-hand side, in *fig. 1.* The rollers, *C, D*, are exactly the same as shewn in *Plate V. figs. 3, 5, and 6*, except that the pinions, *d* and *e*, are omitted, being unnecessary, from the arrangement of the wheels, which we have described. The other rollers at *E F* are made on a very different construction, and are called slitters, because they slit or cut up a bar of iron into several small square bars, of a size proper for nail-makers, or to form hoops for barrels. These slitters consist of two strong axles, mounted in a similar frame to the other rollers; but instead of carrying plain cylindrical rollers, they have rollers composed of steel rims or edges, of the same breadth as the rods they are to slit, and leaving between them deep grooves. The two slitters, or cutters, are so placed in their frame, that the rims of one roller will enter into the grooves between the rims of the other. This will be understood by an examination of *fig. 4. Plate V.*; though the rollers there shewn are for a totally different purpose, still the manner in which the rings of one roller enter the grooves of the other is the same as the slitters: but the proportion of breadth is different, the slitters being made with grooves of half an inch, three quarters, or one inch wide, and many intermediate sizes, corresponding to the

rods to be cut; and they are not made from a solid roller, but are formed of separate circular plates of steel of the just thickness, fitted side by side upon the axis, with circular iron plates of equal thickness between them, which form the spaces; and being of a less diameter than the steel plates, or cutters, they leave deep grooves between the edges. A number of crooked guide-bars are extended across the frame, and pass through the grooves, between the cutters; but lying at the very bottom of the grooves, and not being very thick, they do not fill up the grooves, the circles of the cutters projecting through these bars, which appear like a grate, and one is applied to each roller. Those which are called the guides of the slitters are intended to prevent the iron adhering in the grooves between the rims, or cutters, when pressed down into them; for the action of the slitters is to divide the iron which is passed through them into separate pieces, by the rim of one roller (for instance, the lower) forcing one piece of the bar down into the groove of the lower roller, whilst the adjacent part is forced up, by the rim of the lower roller, into the groove of the upper: the bar is thus divided into as many rods as there are grooves in the width which it covers. The angle at which the circles of the cutters intersect each other, is that in which the edges of a pair of shears are found the most favourable for cutting; and the slitters cut upon the same principle, but with several edges at the same time.

A rolling-mill generally contains a pair of shears, of a sufficient strength to clip off the ends of the largest iron bars, to reduce them to lengths or pieces of a sufficient size for laminating into thin plates. These are made different from other kinds of shears, in the circumstance that the cutting parts, or edges, are situated between the centre pin or joint, and the part or handle where the power is applied: the latter is of great strength, and made exceeding strong in iron. The shears are fixed in a vertical position, the upper blade being firmly fixed by the framing, and the lower one, which is the long lever, is lifted up by the mill when the cut is to be made; therefore it descends when the shears are to open, and its own weight is sufficient for that purpose. The frame consists of a very large and thick iron plate, which is securely bolted down to the foundations: at one end is an upright, which has a groove through it, to receive the moving blade, and guide it; also the end of the handle of the stationary or upper blade is supported by the upper end of this upright. The joint-pin of the two blades is supported in a strong socket, or iron frame, also erected from the same large plate, which carries the upright guide at its other end. The two blades, therefore, lie side by side, and having cutters, or blades, of steel, set into the adjacent sides of the iron levers or blades, the edges of these pass by each other when the cut is made, and will thus cut any thing which is interposed between them, in the same manner as shears or scissars; and in this circumstance is their only resemblance to those instruments. The lower or moving blade, which is a long lever, rests at the extremity, upon the periphery of an elliptical wheel, or cam, (*figs. 1, and 3.*) fixed upon the axis, *I*, of the rollers, (or, in other cases, upon the shaft of the water-wheel,) in an excentric manner, so that, in turning round, it will lift up the lever, and close the shears; but when its opposite or shortest radius comes beneath the lever, it is suffered to descend, and open the blades. At this moment the workman introduces the end of the iron-bar between the blades, pushing the end of it up to a stop, which regulates the length to be cut off; then as the cam turns, it closes the blades, and cuts at once through the bar, although some of the largest are as much as three inches broad, and an inch thick.

## ROLLING-MILL.

Rollers are usually made of cast-iron, and are very exactly turned on their surfaces, and also their necks, that they may turn truly when put in their places. The most common way of turning them is, first to mount the roller in a strong turning lathe, by holes or centre points made in its ends; then to turn the two necks truly cylindrical; and afterwards putting the roller in its proper place in the roller-frame, and placing braffles over the necks, they are held down by blocks, fitted under the pieces which retain the gudgeons of the upper roller: in this situation it is put in motion by the mill, and a bar of iron being fixed up for a rest, the surface of the roll is turned true, in the same manner as if it was in a lathe, and will be certain to be exact, being formed from the same necks on which it is afterwards to work. In casting a roller, the mould should always be placed at a considerable depth beneath the orifice where the metal is poured in, so that the pressure of a column of the fluid metal may be obtained to consolidate the casting, and render it free from those air-holes, or porous places, which will sometimes occur in metals cast without the pressure of a column. The long piece of metal which filled the aperture through which the metal ran, is left adhering to the roller, and is cut off afterwards. This is the same mode of casting that is practiced for cannon (see that article). Case-hardened rollers must be used when it is required to have a very fair surface; viz. for such purposes as rolling iron to make thin plates for tinning; also the large rollers for gold or silver, such as are now used in the Royal Mint; rollers for making tin-foil, steel-plate for saws, and for many other purposes. These rollers are not hardened by a subsequent process, as in case-hardening wrought iron, but are cast in that state. This is effected by employing iron moulds: a cast-iron cylinder of three inches thick, and its diameter equal to that of the roller, is bored out with great accuracy, and fitted with ends proper to form moulds for the necks required at each end of the roller; this is buried in the sand of the foundry, and when the metal is run into it, the rapid transmission of the heat through the iron mould causes the metal which is in contact with it to cool sooner than the other parts of the mass, and renders the surface of the roller very hard. In turning a roller of this kind, the centres must be chosen so that the circumference turns as true as it will admit, and then a very small quantity being taken off, will render it perfect: this care should be taken for two reasons; first, that lefs will be required to be removed to make it true, which is a difficult operation, as only the best steel tools will cut it; also, that if the metal is unequally reduced, or more on one side than the other, the hardest part will there be cut away, and the roller will have a hard and a soft side, and soon wear out of the circular figure, and require a second turning. The less metal there is turned off a case-hardened roller the better it will be, because the hard part is only a case of slight thickness, and most hard at the surface.

The operation of the rolling-mill is so simple, as scarcely to require any description: the metal is heated in reverberating furnaces when it is in large masses, and for smaller pieces a kind of oven is used, in which the coles are laid on the bottom or floor of the oven without any grate-bars, and therefore the draft of air being less rapid, it gives a slight, but very regular heat, which rises to a bright red, but no farther, and therefore it does not waste the iron by burning it to scales, as a greater heat and current of air will do. This oven is proper for heating plates, hoops, or small bars, to be rolled a second and third time: but for rolling large masses, a strong welding heat is requisite, that the metal may be consolidated, and all flaws or cracks securely closed. The

reverberating furnace is used for this purpose; it is made the same as an air-furnace for melting large quantities of iron, except that the floor is horizontal; indeed it is as near as possible similar to the balling furnace. (See *Plate II. Iron Manufacture.*) The furnaces are placed as near as convenient to the rollers.

The iron, being heated in the furnace to the proper degree for the purpose which is intended, is taken out by a pair of pincers, the mill put in motion by drawing the shuttle, and the iron is presented to the rollers, which are previously adjusted to the thickness of the piece which is to be passed. If this is not attended to, and the workmen attempt to reduce the iron too much at one time, there is danger of breaking some of the machinery, or of stopping the mill whilst the iron is only half passed through: this is a disagreeable accident, as it will require four or five men, with an enormous wrench applied to the nuts of the roller, to turn them back sufficiently to relieve the rollers, so forcibly are the ferrets pressed whilst the iron is passing through: this is indeed evinced by the circumstance of solid cast-iron rollers, of ten inches in diameter, being sometimes broken in the middle; and the necks of eight and nine inches are frequently snapped. When the iron is placed on the shelf or table before them, their motion will draw it through, and as they cannot recede from each other, because of the nuts of the bolts, the metal is reduced to the exact thickness of the space between them, increasing in length, but not at all in breadth: the iron is caught by another workman behind the rollers, and returned over the top roller to the first man, who puts it through again, first giving the handles of the nuts a small turn, to bring the rolls nearer together. In this manner it is repeatedly rolled, till it is reduced to any required length and thickness, but the breadth is not at all increased by rolling; and if it is required to increase the breadth, it is done by putting the iron obliquely through the rollers; or if a great increase is wanted, the iron is put through breadthwise two or three times, till it is extended to the length of a gauge which the workman has marked upon the table in front.

*Rolling of black Plate*, such as is used for making the boilers of steam-engines, tanks, or other large vessels, in wrought iron. Such plates, when large, and of considerable thickness, are rolled from the blooms, or half blooms, which are made under the forge-hammer. These blooms, which are also called slabs, are nearly the length of the intended plate; their breadth about one-half or one-third as much as their length, and of a thickness to contain as much metal as will make two, three, or four plates. These pieces, when heated to a white heat, are presented breadthwise to the rollers, and passed through several times at the same heat, until what was the breadth of the bloom, being extended two or three times as great, becomes equal to its length. The thick square plate, thus formed, is now cut up by the shears across into two or three pieces, of about the same size as the first, but in a direction which will make what was the length of the first piece to be the breadth of the second. These pieces, being heated and rolled again, become extended to the size of the required plates: the reason of thus dividing the operation is, that the rolling only extends the metal in the direction in which it moves, and not at all in breadth: by this means, the particles of iron being drawn by the sides of one another, acquire something of a fibrous texture, or an approach thereto, which is desirable in bars, rods, and hoops, but not at all in plate, as it should be equally strong in either direction; therefore, by rolling it first one way, and then the other, the grain, as far as it is produced at all, is in both directions. There is no doubt that better plate would

be made, if the slabs or original pieces were cut to the proper proportions of length and breadth, and of a thickness to form only one piece; then rolling it alternately length and breadth ways every time it is passed between the rolls, and continuing this till the plate is finished, at one heat; a better grain or texture will be thus acquired, because in the former method it will be weaker one way, having something of a grain in the direction of the last rolling.

*Rolling iron Plates which are to be Tinned.*—These are made from the best English iron, and some of the very thinnest from foreign iron; the bars are drawn out, by the forge hammer, to five inches broad, and half an inch thick, and are cut into lengths of eleven inches by the shears; these are heated in an oven, and passed breadthways through case-hardened rolls: this is repeated till they are extended to twice the length of the intended plates: the pieces are then folded, and set on edge in the furnace till properly heated, when they are rolled double, the fold being put in first; they are thus extended to twice the length of the folded plate. Now two men, with strong tongs, tear the two leaves asunder at the fold, and fold each again separately, putting one into the other, like two sheets of paper; in this state they are heated, and rolled four thicknesses together, the next time eight, and so on, till the plate is reduced to the required thickness: in the very thinnest plate, such as is used for tagging laces, sixteen leaves are rolled together. In folding the plates, care is taken every time to put a new surface of metal outside, otherwise, those which were constantly reduced by the pressure of the adjacent leaves, would, at length, become grained on the surface; but by continually gaining new surfaces, which are smoothed by the immediate contact of the rollers, those which are laid against them are also rendered smooth. A small quantity of oil is sprinkled between the leaves, when they are first put in, and instantly spreading over the whole surface, prevents any adhesion; the plates are dressed square by the shears every time before they are folded, to remove those parts which, by projecting over the edges of the other leaves, are not so much reduced.

After being finished, dressed square, and the surface scoured, the plates are rolled, singly, between a pair of polished case-hardened rolls, without being heated; they are therefore extended but little in size, though rendered much harder, and more stiff. *Tin-foil* is rolled much in the same manner as the plates for tinning, but of course without heating.

*Rolling, or Sbling Iron by Rollers.*—This is a modern invention in the manufacturing of bar-iron, the rollers being substituted for the forge hammer to work the metal, in the process of rendering it malleable. This method is only used in conjunction with the *puddling* process, that is, puddling, or converting, cast-iron into a malleable state, by decarbonating it in a reverberating furnace; in this process the metal becomes divided into grains the size of mustard seeds, with a very slight cohesion, and full of interstices between the grains; it therefore requires to be stamped, or hammered, at a welding heat, into a solid mass; but rolling will also answer the purpose.

This was first discovered by the late Mr. Wilkinson, who had, in his extensive works at Broseley, in Shropshire, a pair of enormous rollers, moved by the beam of the steam-engine, not with a rotatory, but with a reciprocating motion: they were five feet diameter, near ten feet long, and weighed almost five tons each, although cast hollow, like garden rollers; sectors were fixed on the ends of the gudgeons, to turn each other, as they did not make above one-third of a revolution, and then moved back again. The circumference

of the rolls were grooved with grooves, gradually diminishing from one end to the other, in the same manner as the rollers shewn in *Plate V. fig. 1.* The mass of iron to be rolled was collected into a ball in the furnace, which was taken out, and passed through the greatest of the grooves. When it came through, a workman at the opposite side removed the ball to the next smallest groove, and by the returning motion of the rollers, it was carried back again to the front: the front workman then returned it in another groove, and so on, passing successively through the different grooves, until, by gradual consolidation, it was reduced to an imperfect bar of malleable iron. A number of these, being cut into lengths, were made up into faggots, or piles, and by a pair of rotatory rollers finished into bars. Mr. Wilkinson had a patent for this machine, but it was afterwards found that other rollers would effect the purpose better. In *fig. 1.* of *Plate V.* is a view of a pair taken from Mr. Samuel Smith's works, at Sheffield, Yorkshire, a gentleman who, we believe, was the first who brought them into use; the two grooves *e* and *f* are very coarse, and have teeth, that they may, more certainly, draw in the balls. The two next grooves are plain but concave, and the remainder are angular, to form square bars when the ball becomes consolidated. The use of these rollers is very similar to those we have just described, the ball of metal being taken from the furnace, and presented to the rolls. As soon as the metal comes through the rollers, a workman behind lifts it over the upper roll to the first workman, who puts it between them again: in this manner the metal is rolled ten or twelve times, being put through a smaller groove of the rollers at each time, so as to compress it in a greater degree every time, till at last it is reduced to a tolerable square bar; but the last groove *E, fig. 2,* has teeth in different parts of the groove, and at such distances from each other, that they will indent so deeply upon the angles of the bars, at every eight or ten inches of their length, as to render it easy to break them into short pieces when they come through. The pieces, thus formed, are piled four together, and put into a ball furnace, and, when heated, they are rolled into bars, by rollers shewn at *fig. 4,* which, at the first five grooves, *e, f,* are similar to the former, but the succeeding grooves, *k, l,* are made to receive the rings of the opposite roll, leaving small rectangular spaces, as is shewn by the light parts, *fig. 4,* through which the iron, being passed, is reduced to a parallel smooth bar. The successive grooves through which it is passed are each made narrower than the preceding, so as to reduce the bars to the width and thickness intended, in which state they are sent to market, or if required for the nail rods, or hoops, are cut up by the slitters. The rollers are thought to inclose the impurities in the iron, rather than expel them; but as rollers require much less power to give them motion than the hammer, it becomes worth the consideration of manufacturers to improve their construction, and render them equal in effect to the hammer. At present the rolled iron is not always so good in quality as the hammered, though this circumstance should not deter manufacturers from using it, as it is scarcely possible that a newly invented process should be at first brought to equal perfection with another which has exercised the ingenuity of manufacturers for ages past. But in the course of practice many improvements may arise, which will remain undiscovered if the process, in its present state, is neglected; even in this state the puddled iron, made with rollers, is by no means to be despised, when its price and quality are compared; it is for iron requiring the fibrous texture that this process is best adapted.

*Rolling and slitting iron for nail rods or small hoops.* The iron

iron which is subjected to this process is brought to the mill, *Plate IV.* before described, from the forge hammer, in bars of a size proportionate to the nail rod it is intended to make; these are cut into lengths by the shears, and heated in the furnace, then rolled repeatedly through the rollers, C, D, which are reduced every time it passes, until the bar becomes of the thickness for the square of the intended rod, half an inch for instance, and two, or two and a half, inches wide: it is, in this state, presented to the slitters E, F, and one end being introduced between the guide-bars of the slitters, is drawn in between them by the motion, and, by this means the ring of one roller presses a corresponding breadth of the hot metal into the space between the rings of the other roller; this being performed by both rollers, completely divides the bar into several rods of the same breadth with the rings of the rollers. A small leaden pipe is fixed over the cutters, and being perforated with holes, constantly lets fall a supply of cold water on the rollers, to prevent their becoming hot, and thus losing their hardness, which alone preserves their circular figure under the intense pressure they have to sustain in dividing the iron. The guide-bars are intended to force the iron rods, when cut, out of the grooves between the rings of the collar, which they would not otherwise quit, after being so forcibly pressed into them by the rings of the opposite roller. For making small hoops, the rods, as soon as they are formed, are put through the plain rolls again, and flattened into a hoop.

*Rolling of Iron Hoops.*—In the country these are made from iron bars, which are reduced in rollers, similar to *fig. 4.*, to a size proper to produce the hoops required; these are cut into lengths, heated, and passed through the slitters, which divide them into three or four rods, which are immediately presented to the case-hardened rolls, and flattened out into a proper hoop. The mill shewn in *Plate IV.* is equally adapted for this work as for nail-rod; but for hoops, the addition of a proper fly-wheel would be an improvement, as the work is so much heavier.

In London, where a vast quantity of old hoops is to be procured, they are re-manufactured, and make the very best fort. The victualling-board alone consume many hundred tons annually for the service of the navy: the old hoops are made up into faggots, and shingled, or welded into bloom at one heat, by a forge-hammer, or in small works by rollers like *Plate V. fig. 1.* The blooms, being again heated, are rolled out into bars by the bar rollers, *fig. 4.* and these are cut into two or three lengths, according to the sizes of the intended hoops; these pieces are heated a third time, slit into rods as above described, and then formed into hoops by the case-hardened rolls. By successive improvements it has been found, that two heats are sufficient, the first for shingling and forming the bars, and the second for slitting and flattening the hoops; but in either method the grand object is by faggoting and rolling, always in the direction of the length, to gain a fibrous texture to the iron.

Old hoops have been lately made up into new at one operation; by employing a greater power and velocity, and making up a smaller quantity at once, it may be effected at a single heat, instead of two or three. For this purpose the old hoops are cut into short lengths and faggoted in piles, the rivets being first cut out and the pieces straightened, that the piles may be more close and compact: these piles are heated in the usual kind of furnace to a good welding heat, and are rolled between the shingling rollers, being passed through two or three grooves till they are properly reduced to go through the flat-grooved bar rollers: after rolling through the three grooves thereof, they are put through the flat parts, and a guide is used to direct them straight forwards, without

care or attention from the workman. The bar is then carried to the cutters, and slit into two or more rods, which are immediately and successively passed between a pair of plain, case-hardened rolls, to finish the hoops.

Vat-hoops, or others above two inches in width, do not require to be slit, but are at once carried from the bar rollers to the plain rollers, which finish them. The piles for shingling must not be made too large, or the hoops will not retain sufficient heat to be found; about 42lbs. will be a proper quantity. The mill for this manufacture must of course have great power, and the rollers should move with a sufficient velocity to enable the iron to be got through the whole process whilst sufficiently hot. The bar and shingling rollers should be placed close together in a line, and must make about 90 revolutions *per* minute; the case-hardened rollers should make 140 *per* minute, and should be placed in such relative situations as will be most convenient to convey the iron in the quickest manner from one pair to the next. A patent has been taken out by some, who pretend to the invention of the above method; but they cannot prevent other manufacturers using it, as it is no new invention, consisting only in taking more care, and using rollers with a greater velocity.

The rolling-mill is not confined to the laminating of iron, but is likewise employed very extensively for reducing brass, copper, tin, lead, as well as gold and silver, into plates and bars. The latter metals are scarcely ever reduced by any other means than rolling; as this method makes no waste, is the most expeditious, and produces better work than hammering, or any other method, particularly when an equality of thickness and an even surface are desired; such, for example, as gold or silver, which is always to receive a polish; in these cases the rollers are made of steel hardened and polished on the surface with the most scrupulous nicety, that they may produce a perfect surface on the matters which have been passed through them.

*ROLLING-Press Printing.* See PRINTING.

*ROLLING*, in *Sea Language*, that motion by which a ship vibrates from side to side. Rolling is, therefore, a sort of revolution about an imaginary axis, passing through the centre of gravity of the ship; so that the nearer the centre of gravity is to the keel, the more violent will be the roll; because the centre about which the vibrations are made is placed so low in the bottom, that the resistance made by the keel to the volume of water which it displaces in rolling, bears very little proportion to the force of the vibration above the centre of gravity, the radius of which extends as high as the mast-heads. But if the centre of gravity is placed higher above the keel, the radius of the vibration will not only be diminished, but such an additional force to oppose the motion of rolling will be communicated to that part of the ship's bottom as may contribute to diminish this movement considerably.

It may be observed, that, with respect to the formation of a ship's body, that shape which approaches nearest to a circle is the most liable to roll; as it is evident, that if this be agitated in the water, it will have nothing to restrain it; because the rolling or rotation about its centre displaces no more water than when it remains upright; and hence it becomes necessary to increase the depth of the hold, the rising of the floors, and dead or riling-wood afore and abaft. See SHIP-BUILDING.

*ROLLING-Tackle.* See TACKLE.

*ROLLING Fork*, in *Geography*, a river of Kentucky, which runs into the Ohio, N. lat. 37° 47'. W. long. 86° 18'.

*ROLLO*, in *Biography*, the first duke of Normandy, was

originally a chieftain or petty prince of Denmark : the king of that country having in vain endeavoured by force to subdue his small territory, lulled him into security by a treaty which he never intended to keep, and then falling perfidiously upon him, killed his brother and many of his officers, and obliged him to take refuge in Scandinavia. Rollo here collected a body of troops, whom he farther attached to his cause by a pretended vision which predicted the certainty of future success ; and then he made a bold attempt upon England, in the latter end of Alfred's reign. The order introduced by that prince having completely foiled the designs of the adventurer, he directed his enterprises to France ; and sailing up the Seine, committed great ravages, and obtained possession of the city of Rouen. He proved himself so formidable an enemy to Charles the Simple, at that time king of France, that he was glad to make a treaty with Rollo, by which he gave him his daughter in marriage, with that part of Neultria called Normandy, for her dower, on the condition that Rollo should do homage for his territory, and embrace the Christian religion. Rollo very readily submitted to the ceremony of baptism, in which he had Robert duke of France for his sponsor, whose name he assumed. In governing the dukedom which he had gained by his sword, the Dane shewed nothing of the barbarian. He divided the land among his followers upon the feudal tenure, established magistracies in the different districts, and took care that law and justice were exactly administered. He severely punished robbery ; treated his French subjects with mildness and equity ; founded bishoprics and religious houses ; and acted, in all respects, like an enlightened sovereign. Such was the reputation of his government, that the country shortly recovered its population and wealth, and many of his roving countrymen settled in Normandy, and became useful and regular subjects. To him is attributed the institution of the exchequer, or ambulatory parliament, which, at a later period, became stationary at Rouen. He died, worn out with the cares of government, in 932, having, five years before this, abdicated his throne in favour of his son William.

**ROLLO**, in *Geography*, an island in the North sea, near the coast of Lapland. N. lat.  $68^{\circ} 15'$ .

**ROLLO'S Head**, a cape on the W. coast of the island of Dominica : three miles S. of Prince Rupert's Head.

**ROLLOCK, ROBERT**, in *Biography*, a learned Scotch divine, was born near Stirling in the year 1556. He studied the classics and belles-lettres under Thomas Buchanan, who has been characterised by Spotswood as learned and wise, and a strong defender of the church's rights, and who then kept a school of considerable reputation. From Buchanan's school Rollock went to the university of St. Andrew's, where he went through a course of philosophy, and, having greatly distinguished himself, he took his degree, and was made regent of his college. In 1580 the magistrates of Edinburgh obtained permission of the king, James VI., to build a college, which being accomplished, Mr. Rollock was, in 1583, chosen the principal, and first theological professor. His high character, though not thirty years of age, brought numerous students to the new university. His reputation extended to foreign countries, where he was greatly respected by the reformed churches. He died in the year 1598, when he had only reached his forty-third year. He was author of many works, among which are the following : " In selectos aliquot Psalmos Davidis Commentarius ;" " In Daniele Prophetam Commentarius ;" " In Epistolam fec. Sanctum Johannem Comment." He published commentaries on some of the other epistles ; also " Analyfis Logica in Epistolam ad Hebræos."

**ROLPACH**, in *Geography*, a town of Thibet, capital of a district ; 150 miles N. of Fyzabad. N. lat.  $29^{\circ} 21'$ . E. long.  $82^{\circ} 5'$ .

**ROLSHUGARDE**, a town of Norway ; 46 miles S. S. E. of Drontheim.

**ROM**, an island in the North sea, near the coast of North Jutland, about eight miles long and two wide. N. lat.  $55^{\circ} 9'$ . E. long.  $8^{\circ} 31'$ .

**ROM**, a town of France, in the department of the Vienne ; 10 miles S. of Lusignan.

**ROMA**, an island in the East Indian sea ; about 20 miles long, and from 6 to 12 broad. S. lat.  $7^{\circ} 12'$ . E. long.  $127^{\circ} 12'$ .

**ROMAGNA**, a late province of Italy, bounded on the N. by the Ferrarese, on the E. by the Adriatic, on the S. by the duchy of Urbino and Tuscany, and on the W. by Bologna ; about 45 miles long and 30 broad. This country, which was part of the ancient Flaminia, fell, in the fifth century, under the dominion of the Ostrogoths ; whose king, Theodoric, after having taken the city of Ravenna, in the year 493, made it the place of his usual residence. In the following century, the Goths, being driven out by Belisarius and Narfes, generals of the emperors of the East, Ravenna became the residence of the emperor's exarch, till the Lombards made themselves masters of it, and dispossessed the last exarch. In the year 755, Pepin, king of the Franks, having compelled Itulphus, king of the Lombards, to cede the whole exarchate, conferred it on the see of Rome. It now forms the departments of the Amone or Lamone, and the Rubicon, in the kingdom of Italy, being surrendered by the pope in 1797. See **EXARCH**, and **RAVENNA**.

**ROMAGNANO**, a town of Italy, in the department of the Gogna, on the Sesia ; 15 miles N. N. W. of Novara.

**ROMAGNE, LA**, a town of France, in the department of the Mayne and Loire ; 6 miles W. of Chollet.

**ROMAGNE sous les Côtes**, a town of France, in the department of the Meuse ; 9 miles N. W. of Eftain.

**ROMAGNO**, a town of Italy, in the Feltrin ; 6 miles N. E. of Feltri.—Also, a town of the island of Sardinia ; 12 miles N. N. E. of Sassari.

**ROMAHIE'**, a town of the Arabian Irac, on the Euphrates ; 100 miles S. of Bagdad. N. lat.  $31^{\circ} 40'$ . E. long.  $44^{\circ} 15'$ .

**ROMAIN**, in *Husbandry*, the name of a plant, cultivated in the fields, in many parts of the world, particularly in France, and called, by our farmers, *French vetches*, or *French tares*. It is an annual plant, but a very quick grower, and is extremely good food for cattle, particularly for horses : they let these creatures feed on it all the former part of the summer, and then cut it for hay in August or September. Its short continuance in the ground makes it less valuable than faint-foin and clover ; but it has this advantage over them, that it will grow on poor ground.

**ROMAIN, Cape**, in *Geography*, a cape on the south coast of Madagascar. S. lat.  $35^{\circ} 38'$ . E. long.  $49^{\circ} 29'$ .

**ROMAIN, St.**, a town of France, in the department of the Charente ; 3 miles N. W. of Aubeterre.—Also, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of La Havre ; 7 miles E. of Montivilliers. The place contains 1200, and the canton 11,569 inhabitants, on a territory of 155 kilometres, in 28 communes.

**ROMAIN d'Alban, St.**, a town of France, in the department of the Drôme ; 15 miles N. N. W. of Romans.

**ROMAIN en Jarez, St.**, a town of France, in the department

ment of the Rhone and Loire; 12 miles N.N.E. of St. Etienne.

ROMAINE, WILLIAM, in *Biography*, a very popular divine of the church of England, was born at Durham in 1714, and educated at Hertford college, Oxford: from whence he removed to Christ-church, where he took his degrees in arts. On entering into holy orders, he became a frequent preacher before the university, and was noted for his zeal in behalf of what were deemed the orthodox doctrines. He removed to London in 1749, and became lecturer at St. Dunstan's church, Fleet-street. He was, for a short time, morning preacher at St. George, Hanover-square, and professor of astronomy at Gresham college, which situation he soon resigned. In 1764 he was chosen rector of St. Anne, Blackfriars, where, and at St. Dunstan's, he continued to preach to large and very crowded congregations almost to his death, which happened in the year 1795. Towards the close of life his voice was feeble, but his manner was very impressive. His works, which are theological, and on the Calvinistical scheme, have been collected in 8 vols. 8vo. He was editor of Calasio's Concordance to the Hebrew Bible, in 4 vols. folio, in 1749; in which, it is said, he made some unwarrantable alterations to serve the Hutchinsonian doctrine.

ROMAINMOTIER, in *Geography*, a town of Switzerland, in the canton of Berne, from which a bailiwick derives its name; 11 miles S.W. of Yverdon.

ROMAINVILLE, a town of France, in the department of Paris; 5 miles E. of Paris.

ROMALE, a town of Sweden, in West Gothland; 35 miles W.S.W. of Skara.

ROMAN, a town of European Turkey, in Moldavia, on the Siret, the see of a Greek bishop; 145 miles W. of Bender.

ROMAN, *Cape*, a cape on the west coast of East Florida. N. lat. 25° 40'. W. long. 82° 25'.—Also, a cape on the coast of Chili, in the South Pacific ocean. S. lat. 48° 20'. W. long. 76° 40'.—Also, a cape on the coast of South Carolina. N. lat. 33° 5'. W. long. 79° 30'.—Also, a cape on the coast of Florida, 20½ leagues N.W. by N. from Cape Sable, the S.W. point of the peninsula of Florida.—Also, a cape on the north coast of Terra Firma, being the north point of the peninsula, which is the east limit of the gulf of Venezuela. Due north of it is the island of Orua, or Araba, at eight or nine leagues distance, belonging to the Dutch.

ROMAN *County*, a county of North Carolina, containing 21,543 inhabitants.

ROMAN, something belonging to the city of Rome.

ROMAN *Monarchy*. See MONARCHY, and ROME, infra.

ROMAN, or *Romish Church*, is that of which the pope is head, so called in opposition to the reformed churches. See PAPISTS, and POKERY. See also CHURCH and REFORMATION.

The Roman law is the civil law, or the written law, as compiled by the emperor Justinian.

ROMAN *Ecclesiastical Singing and Music*, during the middle ages. These were in such general favour throughout Europe, that it was the custom, during the times of the greatest musical and mental darkness, when reason and reflection were the least cultivated, for the priests, of almost every part of Europe, to visit Rome, in order to learn canto fermo, and the manner of performing those rites of the church, in which music had any concern. Even those historians who are the least friends to bigotry, and the most ready to combat superstition and papal usurpations, allow that it was only at the court of Rome that the arts of elegance and refinement were at all cherished, during these

times. King Pepin, Charlemagne, and Alfred, had applied to the Roman pontiffs for singing-masters to instruct their subjects.

The learned Jusquin went thither as a singer, during the pontificate of Sixtus IV. And before the year 1600, the names of near twenty Spanish singers and composers are recorded, who were employed in the pontifical chapel. Yet all this proves nothing more than that musicians of great abilities, from whatever part of the world they came, were certain of encouragement there. For more facts to this purpose, see ITALY.

ROMAN *Games, Ludi Romani*, were solemn games, held in ancient Rome, thus called by way of eminence, and on account of their antiquity, as having been instituted by Romulus.

They were sometimes also called *magni ludi*, from the great pomp and expence of them; and sometimes *consualia*, because performed in honour of the god Neptune, who was also called *Consus*, in his quality of god of secret counsels.

They also bore the denomination of *ludi Circenses*, because held in the Circus.

This solemnity, Halicarnassus observes, was originally instituted by Evander, in honour of Neptune, under the name of *Ἰππιόες*, whence the festival itself was called *Ἰππιό-κεχθία*; and was afterwards renewed by Romulus, in honour of the same deity, only under another name.

For Romulus, needing the advice of a god to counsel him in the design he had to furnish his new citizens with wives, applied to the god of secret counsel himself, Consus; proclaimed the Consualia; and invited his neighbours all around to the first celebration thereof. The consequence was the rape of the Sabine women, who came to be spectators of it.

The great ceremony, in these games, consisted in a cavalcade of horses and asses, adorned with garlands; Neptune being reputed the first author of riding on horseback.

Their horses here were of two kinds; viz. *πορπητικοί*, or such as were merely led up and down for state; and *δρομικοί*, which were for race and exercise.

The other diversions were fencing, and that till one of the combatants was killed on the spot; fighting with beasts, and with the cæstus, or whirlbats; wrestling, running, leaping, sea-fights, horse-races, chariot-races, &c.

These games, Livy tells us, were improved, and rendered much more magnificent, by Tarquinius Priscus. Manutius says, they were held on the eve of the nones of September; i. e. on the 14th day of the month.

ROMAN *Operas*. In treating of the progress of the musical drama, in that ancient and renowned capital, during the former part of the 17th century, it does not appear that any regular theatre was opened there for the performance of operas; nor, indeed, can we discover that any secular musical drama was exhibited there till the year 1632, when "Il Ritorno di Angelica nell' Indie, Drama Musicale," is recorded by Leo Allacci, in his *Drammaturgia*, to have been performed in that city; but without informing us where, or by whom set to music or sung. Several musical dramas, however, were performed there at the palaces of ambassadors, and other great personages, between 1632 and 1661, when "Clearco," set by Tenaglia, a Roman master, was performed. This composer, who had distinguished himself by his productions for the church, is celebrated by P. Della Valle among great Roman musicians in 1640.

The first public theatre, opened for the exhibition of musical dramas at Rome, in modern times, was il Torre di Nona, where "Giasone" was performed, 1671. No

other theatre seems to have been used for this purpose in that city till 1679, when the opera of "Dov' è Amore, è Pietà," set by Bernardo Pasquini, the famous organist, was represented Nella Sala de' Signori Capranica. This theatre still subsists.

ROMANS, *King of the*, in *Modern History*, is a prince elected and designed successor to the German empire.

ROMANCE, anciently *Romount*, and *Romant*, a fabulous relation of certain intrigues and adventures in the way of love and gallantry, invented to entertain and instruct the readers.

M. Fontenelle calls romances poems in prose; and Bossu is not averse to their being admitted as poetical pieces, though not written in verse.

Setting aside the versification, it is certain an epic poem and a romance are almost the same thing. The just notion, therefore, of a romance is, that it is a discourse invented with art to please and improve the mind, and to form or mend the manners, by instructions, disguised under the allegory of an action, or series of actions, related in prose, in a delightful and probable, yet surprising manner.

A just romance consists of two parts: *viz.* a moral, as its foundation, and end; and a fable, or action, as the superstructure and means.

It must also have the manners; that is, the characters must be distinguished, and the manners must be necessary; and it must have all the other qualities of poetical manners.

The incidents must be delightful, and, to that end, rightly disposed and surprising. The sentiments fall under the same rules as in the drama.

But the diction is allowed to be more lofty and figurative; as being a narration, and not having terror or pity, but admiration for its end.

A romance of chivalry, according to the definition of a late writer, is any fabulous narration, in verse or prose, in which the principal characters are knights, conducting themselves, in their several situations and adventures, agreeably to the institutions and customs of chivalry.

As compositions of this kind have a long time been little else but histories of amorous adventures, and feats of knight-errantry, the origin of romances is referred to that of love-histories; and accordingly Dearchus, a disciple of Aristotle, who first wrote of those matters, is usually termed the original author of romances. Though Photius is of opinion, that Antonius Diogenes's book on the errors and amours of Dinias and Dercyllis gave birth to most of the works of this kind. Be this as it will, it is certain the ancients have had their romances as well as we. Such are the amours of Rhodanis and Simonides, described in iambs; such is the romance of Leucippe and Clitophon, composed by Achilles Tattius, a Greek writer, afterwards a bishop; such are the Four Books of Incredible Things, written by Damascius; such are the Ethiopics of Heliodorus, in which he relates the amours of Theagenes and Chariclea. Lastly, under the same class may be ranked the Fables of Parthenius Nicemus,

of Athenagoras, Theodorus Prodromus, Eustathius, and Longus.

Indeed antiquity could scarce be reconciled to such pieces, and always looked on them as abuses. Photius, in his Bibliotheca, cod. lxxxvii. gives a frightful account of that of Tattius; and the Ethiopics of Heliodorus, though one of the most modest and most reserved pieces of the kind, met with a very severe treatment. The author was bishop of Tricea, in Thessalia, in the fourth century. Nicephorus tells us, that a synod, considering the danger which might accrue to youth from reading his romance, authorised as it was by the dignity of its author, proposed it to him, either to suppress his book, or renounce his bishopric; and that he chose the latter. But this history is a little doubtful.

Be this as it will, Heliodorus has served as a model to all the romances written since; and the marriage of Theagenes and Chariclea has produced a very numerous issue, even all the romances now extant in the world.

Mr. T. Warton, in his "Dissertation on the Origin of Romantic Fiction in Europe," prefixed to the "History of English Poetry," vol. i. is of opinion, that the peculiar and arbitrary species of fiction, which we call romantic, was entirely unknown to the writers of Greece and Rome; and it appears to have been imported into Europe by a people, whose modes of thinking, and habits of invention, are not natural to that country. Whatever be their origin, which will be a subject of inquiry in the sequel of this article, it must be allowed that the ancient metrical romances were very early superseded by prose works upon the same subjects. These last, although far inferior, in interest and merit, to the poetical tales which preceded them, claimed and obtained a superior degree of credit, founded upon the fiction alleged to be inseparable from metre; upon the degraded state of the minstrels, whose province it was to recite these disparaged rhyming legends; and, above all, upon a grave pretext set up by the author of each prose work, that he had translated it *verbatim et literatim* from an ancient Greek or Latin original. As no such Greek or Latin original for a romance of chivalry has ever been produced, we may be safely allowed to doubt whether any such ever existed. But our ancestors received these accounts with unhesitating credulity, and gravely read the voluminous romances of Lancelot du Lac, and Palmerin of England, as translations from ancient annals, while they rejected with scorn the rhyming legends of the minstrels on the same subjects. Thus the metrical romances were obliged to give way to the prose works, which were, in fact, borrowed from them; and so complete was the substitution of the one species of fable for the other, that the press, which was then invented about the period of this revolution in public taste, groaned under the splendid folios of the former, while the latter remained in obscure manuscripts, or were only printed in the meanest manner, and for the meanest of the people. Thus the very existence of the metrical romance, as a distinct, separate, and more ancient kind of composition, was unknown and unnoticed till the publication of the works of some modern writers.

Bishop Percy, the venerable editor of the "Reliques of Ancient Poetry," seems to have been the first person in our country who directed the public attention to this subject, by an "Essay upon Metrical Romance," prefixed to the third volume of his work, in which the merits and qualities of the poetry and chivalry are critically investigated, and a list given of such metrical romances as had come to his knowledge. The learned prelate was followed by Mr. T. Warton; and not to mention the collectors and publishers, of some of the shorter and more ancient of our metrical tales

## ROMANCE.

of chivalry, both in London and Edinburgh, the first comprehensive and general work upon this intersting subject was undertaken by Mr. Ritson, which was soon succeeded by the more popular and elegant performance of Mr. George Ellis, entitled "Specimens of early English Metrical Romances, chiefly written during the early Part of the 14th Century: to which is prefixed a historical Introduction, intended to illustrate the Rise and Progress of Romantic Composition in France and England." Mr. Ritson's work is a selection of "Ancient English Metrical Romances," containing twelve metrical romances of chivalry; to which is prefixed a long and elaborate dissertation on Romance and Minstrelsy.

In imitation of the archbishop Turpinus, who passed for author of the romance of the Fealts of Charlemagne and Orlando, a great number of histories, of the like kind, were written in France, during the time of Philip the Fair; the authors of which seemed to improve on each other, contending who should go farthest in the merveilleux. These books, being intended for polite people, were written in the court language of that age, which was called the *romans*, *romant*, or *romantic*; whence the books themselves were called by those names: and thus, by degrees, *romans*, &c. became the general name of all books of this kind; whence, at length, our *romance*.

To this purpose, Crescimbeni, reciting the several opinions respecting the name *romanza*, derives it from the word *Roma*, and tells us, that it means that vulgar idiom which, with colonies of Romans, passed into Provence, and elsewhere, and was esteemed, even by the barbarians who inhabited those kingdoms, and called *Romano* and *Romanzo*; and in this they wrote the acts and achievements of knights; which writings were, therefore, styled *romanzi*, or *romances*.

Others derive the word from the Spanish *romanfero*, *I invent*; as intimating romances to be mere fictions. And hence it is that the ancient poets of Provence, who were the first great dealers in romances, are called *troubadours*, *q. d.* finders, or inventors.

Crescimbeni remarks, that the Italians derived from Provence, not only the origin and art of writing romances, but also the very subjects on which they were founded; and though it is not precisely known who were the romance writers of Provence, yet many of their romances are found in the Italian libraries; and, indeed, from such a source of poetical fiction as the country of Provence appears to have been, nothing less could be expected than a vast profusion of romances, and other works of invention. See *PROVENÇAL Poets*, and also *MINSTRELS*, with whose history that of romances, of which they were the composers, is nearly connected.

It has been a received opinion amongst modern critics, that the fictions of romance, borrowed from the Arabians, were communicated to the Western world by means of the Crusades. Mr. Warton (*ubi supra*) is of opinion, that although these expeditions greatly contributed to propagate this mode of fabling in Europe, they were introduced at a much earlier period by the Saracens, or Arabians, who came from the northern coasts of Africa, and settled in Spain, about the beginning of the eighth century. From Spain, he imagines, they found an easy passage into France and Italy; and the close connection which subsisted for many centuries between the Welsh and their colonists, the Armorians, might have been the means of bringing them from France into this island. (See *ARMORICA*.) A strict intimacy also subsisted between Cornwall and Wales; and hence we are able to account for Cornwall's being made the

scene and the subject of so many romantic adventures in the French romances. Their language, customs, and alliances were the same; and by British writers, Cornwall, separated from Wales only by a strait of inconsiderable breadth, is frequently styled West Wales. At the invasion of the Saxons, both countries became indiscriminately the receptacle of the fugitive Britons. We find the Welsh and Cornish, as one people, often uniting themselves as in a national cause against the Saxons. They were frequently subject to the same prince, who sometimes resided in Wales, and sometimes in Cornwall; and the kings or dukes of Cornwall were perpetually celebrated in song by the Welsh bards. Traditions about king Arthur are as popular in Cornwall as in Wales; and most of the romantic castles, rocks, rivers, and caves, of both nations are alike distinguished at this day by some noble achievements, at least by the name of that celebrated champion.

Arthur and Charlemagne, according to Warton, are the first and original heroes of romance. And as Geoffroy's history is the grand repository of the acts of Arthur, so a fabulous history, ascribed to Turpin above-mentioned, is the ground-work of all the chimerical legends which have been related concerning the conquests of Charlemagne, and his twelve peers. Its subject is the expulsion of the Saracens from Spain: and it is filled with fictions evidently congenial with those which characterize Geoffroy's history. Some have supposed this romance to have been written by Turpin, a monk of the eighth century, who for his learning, and sanctity, and gallant exploits against the Saracens of Spain, was preferred by Charlemagne to the archbishopric of Rheims. Others suppose it to have been forged under archbishop Turpin's name, about that time; others, very soon afterwards, in the reign of Charles the Bald, that is, about the year 870. Historical evidence concurs with numerous internal arguments to prove, that it must have been compiled after the crusades, or about the year 1110. In the two fabulous chronicles now mentioned, the foundations of romance seem, in Mr. Warton's opinion, to be laid. The principal characters, the leading subjects, and the fundamental features, which have supplied such ample matter to this singular species of composition, are here first displayed. And although the long continuance of the crusades imported innumerable inventions of a similar complexion, and substituted the achievements of new champions, and the wonders of other countries; yet the tales of Arthur and Charlemagne, diversified indeed, or enlarged with additional embellishments, still continued to prevail, and to be the favourite topics. Upon the whole Mr. Warton concludes, that these volumes are the first specimens extant in this mode of writing; but he considers the Saracens, either at their immigration into Spain, about the ninth century, or at the time of the crusades, as the first authors of romantic fiction among the Europeans.

In examining the hypothesis of Dr. Percy and Mr. Mallet, who derive these fictions, in a lineal descent, from the ancient historical songs of the Gothic bards and scalds, he allows this opinion to be in some measure well founded, and that so far it is also reconcileable with his own system.

The scaldic inventions, he says, had undoubtedly taken deep root in Europe, and prepared the way for the more easy admission of the Arabian fabling, about the ninth century, by which they were, however, in a great measure superseded. As a proof of which he observes, that the enchantments of the Runic poetry are very different from those in our romances of chivalry. The former chiefly deals in spells and charms, such as would preserve from poisons, blunt the weapons

weapons of an enemy, procure victory, allay a tempest, cure bodily diseases, or call the dead from their tombs, in uttering a form of mysterious words, or inscribing Runic characters. The magicians of romance are chiefly employed in forming and conducting a train of deceptions. There is an air of barbaric horror in the incantations of the scaldic fablers: the magicians of romance often present visions of pleasure and delight: and although, not without their alarming terrors, sometimes lead us through flowery forests, and raise up palaces glittering with gold and precious stones. The Runic magic is more like that of Canidia in Horace, the romantic resembles that of Armida in Tasso. The operations of the one are frequently but mere tricks, in comparison of that sublime solemnity of necromantic machinery which the other so awfully displays.

He adds, it is also remarkable, that in the earlier scaldic odes we find but few dragons, giants, and fairies. These were introduced afterwards, and are the progeny of Arabian fancy. Nor, indeed, do these imaginary beings often occur in any of the compositions which preceded the introduction of that species of fabling.

That the ideas of chivalry, the appendage and the substance of romance, subsisted among the Goths, our author readily allows, but not without certain limitations. It was under the feudal establishments, which were soon afterwards erected in Europe, that it received new vigour, and was invested with the formalities of a regular institution.

From the whole of his observations, the author deduces the following general conclusion.

Amid the gloom of superstition, in an age of the grossest ignorance and credulity, a taste for the wonders of oriental fiction was introduced by the Arabians into Europe, many countries of which were already seasoned to a reception of its extravagancies by means of the poetry of the Gothic scalds, who, perhaps, originally derived their ideas from the same fruitful region of invention. These fictions, coinciding with the reigning manners, and perpetually kept up and improved in the tales of troubadours and minstrels, seemed to have centered, about the eleventh century, in the ideal histories of Turpin and Geoffrey of Monmouth, which record the supposititious achievements of Charlemagne and king Arthur, where they formed the ground-work of that species of fabulous narrative called romance. And from these beginnings, or causes, afterwards enlarged and enriched by kindred fancies, fetched from the crusades, that singular and capricious mode of imagination arose, which at length composed the marvellous machineries of the more sublime Italian poets, and their disciple Spenser.

Hearne imagines, that the old metrical romance, called "Richarde cuer de Lyon," was written by Robert de Brunne. It is probable, however, that the leisure of monastic life produced many rhymers, nor is it at all unlikely, but that the monks often wrote for the minstrels, and that many of our ancient tales in verse, containing fictitious adventures, were written, although not invented, in the religious houses. The romantic history of "Guy earl of Warwick" is expressly said, on good authority, to have been written by Walter of Exeter, a Franciscan friar of Carocus in Cornwall, about the year 1292. (Carew's Survey of Cornwall, p. 59.) The libraries of the monasteries were full of romances. Among the many French minstrels invited into England by Richard I., it is natural to suppose that some of them made their magnificent and heroic patron a principal subject of their compositions. We have a romance now remaining in English rhyme (which we have just mentioned) that celebrates the achievements of this il-

lustrious monarch. It is called "Richard, &c." and was probably translated from the French about this period. That this romance, either in French or English, existed before the year 1300, is evident from its being cited by Robert of Gloucester, in his relation of Richard's reign, and also by Robert de Brunne, who wrote much about the same time with Robert of Gloucester; and hence we may infer that Hearne must be mistaken in supposing that he was the author of it.

The French, above all other nations, have applied themselves to this kind of writing; whether it be owing to the natural taste and genius of the people, or to the freedom, &c. with which they converse with the women. They appear to have written metrical romances before or about the year 1200. Some of these seem to have been formed from prose histories, enlarged and improved with new adventures and embellishments from earlier and more simple tales in verse on the same subject. They began chiefly with romances of chivalry: hence their Amadis, in twenty-four volumes; Palmerin d'Oliva; and of England, king Arthur, &c. of which we have an agreeable critique in Don Quixote.

Chrestien of Troys wrote "Le Romans du Graal," or the adventures of Sangrale, which included the deeds of king Arthur, sir Tristram, Lancelot du Lake, and the rest of the knights of the round table, before 1191. Chrestien also wrote the romance of "Sir Percival," and left unfinished "La Charette," containing the adventures of Lanucelot. The first French writers of romance were the *Troubadours*; which see.

The later romances are much more polite; the best of which are the Astrea of d'Urfe; the Cyrus and Clelie of Mademoiselle de Scuderi; the Cassandre and Cleopatre of La Calprenede; Ariane, Francion; and the Adventures of Telemachus, by the late archbishop of Cambrai, worth all the rest.

The Germans, too, have their romances; especially Hercules and Herculesus, the Aramena, Octavia, Arminius, Otbert, &c.

The Italians have their Eromena, by Biondi; the works of Loredano, Marino, &c. The Spaniards, who, from their temper and constitution, were extravagantly fond of chivalrous exercises, had their Amadis of Gaul, their Diana, and Don Quixote. Some critics have even supposed, that Spain, having learned the art of romance-writing from their naturalized guests the Arabians, communicated it at an early period to the rest of Europe. The English, their Arcadia, &c. And in modern times, the number has been so great, that our circulating libraries are full of them.

The Argenis of Barclay is rather a satire than a romance. Although we owe to the Norman minstrels the greater part of the romances now extant, which were avowedly translated into English, as soon as that language superseded the French; yet some few were most probably originally composed in English for the use of the Scottish court, where French was never exclusively spoken, and afterwards imitated or translated by French minstrels. Hence it is curious to observe, that as the earliest French romances were written in England, so the earliest English romances were composed in Scotland.

Mr. Ellis makes an arrangement of romances into classes, introducing each with appropriate remarks. The first class comprehends romances relating to king Arthur; which were probably the earliest in order, and were most popular and numerous. The next class included what he has ventured to call Saxon romances, that is, romances referring to Saxon subjects, and claiming, perhaps, some foundation in the history of that people. Guy of Warwick and Bevis  
of

of Hamptoun occupy this station entirely. These two, notwithstanding their demerits, equalled, or excelled in popularity, almost all the romances of the middle ages. The next is entitled an Anglo-Norman romance, and recites the adventures of no less a person than Richard Cœur de Lion. The next class of romances comprehend such as relate to Charlemagne and his Paladins. Under this head Mr. Ellis has enumerated three, *viz.* Roland and Ferragus, Sir Otuel, and Sir Ferumbras. The next romance is of oriental origin, being the earliest tradition of the Seven Wise Masters, long known among the school-boys of this country. To this he has added ten miscellaneous romances, which we must content ourselves to pass over without mentioning their names. The importance of the ancient metrical romances in an historical point of view must be acknowledged. They hold out to us, like Shakspeare's plays, the abstract and brief chronicles of the time, and demand the consideration of every historian. Even in a literary point of view, their merit is not contemptible. It is true, the story is generally rambling and desultory, utterly incapable consequently of exciting the pleasure arising from a well-conducted plan, all the parts of which depend upon each other, and tend, each in due degree, to bring on the catastrophe. So far is this from being the case, that in a long romance, the adventures usually are all separated and insulated; only connected with each other, by their having happened to the same hero; just as a necklace of beads is combined by the thread on which they are strung. This arrangement, in fact, best suited the reciters, whose narration was to be proportioned to the time and patience of their audience; and whom this loose structure of story permitted to use freedom of compression or dilatation as best suited their purpose, since any single adventure might be inserted without impropriety, or left out without being missed. The same cause accounts for the loose and often tedious style in which the minstrels indulged. It was of consequence that their stanza should be so simple, as to be easily recollected, and their diction so copious, as not to suffer by any occasional deficiency of memory. For these reasons, Robert de Brunne tells us, that the common minstrels were unable to repeat tales written in a concise style and complicated stanza, and that such became *naught* in their imperfect recitation. To these faults, we have often to add those of extreme awkwardness of contrivance and improbability of incident; but which neither offended the taste, nor shocked the faith of our plain and hardy ancestors. On the other hand, there is a sort of *keeping* in these ancient tales, which did not depend upon the minstrel's inclination, and from which he could not have departed, if he had a mind to do so. This arises from his painting the manners of his own time, as they passed before his eyes, and thus giving a truth and unity to the chivalrous events he relates, which the modern labourers in the vineyard of romance are utterly unable to imitate. With all the pains these last can use to deck their champions in the antique taste, they are perpetually confounding the past time with the present, and are guilty of anachronisms almost as gross as his who introduced a tea-table scene into the history of John of Gaunt. Neither is the language in which these legends are told altogether unworthy of our applause. There often occur passages, which, from the spirit of the poet rising with the situation, may justly claim a rank among the higher and more masculine orders of poetry. And although, as we have already noticed, the general conduct of the story is desultory and slightly put together, yet many of the individual adventures, of which each long romance is composed, are happily conceived and artfully executed. The gloom of superstition likewise added a wild and dismal effect to the wonders of

the minstrel; and occasionally his description of supernatural events amounts nearly to sublimity. See Warton, Ritson, Ellis, *ubi supra*, and Edinb. Review, N° XIV.

ROMANCHE, LA, in *Geography*, a river of France, which runs into the Drac, a little above Grenoble.

ROMANENGO, a town of Italy, in the department of the Upper Po; 4 miles E. of Crema.

ROMANIA, a province of European Turkey, containing the territory anciently denominated "Thrace," and deriving its present name from New Rome, by which Constantinople was distinguished. The Turks call it "Rumelia" or "Rumili," and "Icelia;" and it is also denominated "Romelia." This province is bounded on the N. by Bulgaria, on the E. by the Black sea, on the S. by the sea of Marmora and the Archipelago, and on the W. by Macedonia. It is upon the whole a level country, though famous for some of its mountains: such are mount Hamus, which separates it on the N. from Bulgaria; Rhodope, celebrated among the ancients for the catastrophe of Orpheus; and mount Pangæus, which divides this country from Macedonia. The two former are long ridges of mountains, that extend from the frontiers of Macedonia to the Black sea. The territories that lie among the mountains are cold and barren; but those near the sea are pleasant and fertile, producing all kinds of grain, and particularly rice of good quality. This country was anciently divided into several independent kingdoms: and the Thracian Chersonesus was also governed by its own kings. The present inhabitants are Greeks, descended from the ancient Thracians, interperfed with Turks. Thrace (which see) was formerly distinguished by the cultivation of the sciences and fine arts; but the present state of Romania is very different, being wholly destitute of persons of literature. It is governed by three Sangiaks, and divided into as many districts under the denomination Sangiacates. The capital is *Constantinople*, which see.

ROMANIA, *Cape*, a cape on the S.E. point of Malacca. N. lat. 1° 18'. E. long. 104° 15'.

ROMANO, GIULIO, in *Biography*, the cognomen of Giulio Pippi, the most renowned among the immediate scholars of Raphael d'Urbino, his heir, and the continuator of his works. He was born at Rome in the year 1492. While a pupil, he followed less his master's delicacy than energy of character, and chiefly signalized himself in subjects of war and battles, which he represented with equal spirit and erudition. As a designer, he commands the whole mechanism of the human body; and, without fear of error, turns and winds it about to serve his purposes, but sometimes overleaps the modesty of nature. Vafari, who visited him at Mantua, prefers his drawings to his pictures, as being more full of that original fire which distinguishes his conception, and was apt to evaporate in the longer process of finish: some have, with better evidence, objected to the character of his physiognomies, as more sagacious than enamoured, less simple than vulgar, and often dismal and horrid, without being terrible. In colour, whether fresco or oil, his hand was as expeditious, and his touch, especially in the former, as decided, as his eye and choice were congenial. Brick lights, violet demi-tints, and black shades, compose in general the raw, opaque tone of his oil pictures; far different from that characteristic tone which signalizes the Battle of Constantine, painted by him from the design and after the death of Raphael, and which was by Poussin admired as being most happily adapted to the subject. The style of his draperies is classic, but the arrangement of the folds generally arbitrary and mannered; the hair and head-dresses of his women are always fanciful and luxurious, but

not always arranged by taste; whilst those of his men frequently border on the grotesque.

After he had completed the Hall of Constantine in the Vatican from the design of his master Raphael, he went to Mantua, where the increased practice and authority, derived from the superintendance of the great works he had just completed, established his reliance on himself; and the patronage of the Gonzaghi roused that loftiness of conception, and gave birth to those magnificent plans, from which Mantua and the palace *del T.*, as from enchantment, rose. To the stores of antique treasures belonging to this great family, of which the statues, busts, and bas-reliefs at present in the academy are but insignificant remains, he added his own; rich in designs of Raphael, and in studies and plans from the antique. No designer ever possessed such industry with so much fire, so much consideration with such fecundity, or combined with equal rapidity such correctness, with great recondite knowledge in mythology and history, and that popularity and care in treating it.

The palace *del T.* furnishes specimens in every class of picturesque imagery. Whatever be the dimension, the subject, or the scenery, minute or colossal, simple or complex, terrible or pleasing, we trace a mind bent to surprise or to dazzle by poetic splendour; but sure to strike by the originality of his conception, he often neglects propriety in conducting his subjects, considered as a series; and in the arrangement or choice of the connecting parts, hurried into extremes by the torrent of a fancy more lyric than epic, he disdains to fill the intermediate chasms, and too often leaves the task of connection to the spectator.

In this palace, Giulio adopted the method of his master. He prepared the cartoons, and the pictures were executed by his pupils; but he retouched, corrected, and gave the last finish to them: unfortunately, his master-strokes have been covered again by modern pencils; and the fable of Psyche, the Allegories of Human Life, the Giants storming Heaven, exhibit now indeed his composition and design, but not his hand: this is better preserved in the paintings of the old palace, or, as it is now called, the Corte of Mantua; which are in fresco, and relate chiefly the histories of the Trojan war. They have the same beauties and defects as those of the palace *del T.*: each singly considered is a proof of the poetic spirit and the practical powers of the master; as a cyclus they want connection and evidence. Helen sleeping, Vulcan forging Arms for Achilles, are beautiful; and Minerva in the act of slaying Ajax, the son of Oileus, sublime. Nor is his versatility less admirable in the Bacchic or amorous subjects; the *capricci* and grotesque conceits with which he decorated the small cabinets of the same palace.

The altar-pieces of Giulio are not numerous. He did not live to finish those which he had begun for the cathedral of Mantua. The most remarkable of those which he finished with his own hand, are the three frescoes at St. Marco; and in the church of St. Cristoforo, the athletic figure of that saint, groaning under the weight of the divine Infant on his shoulders. They are, however, far inferior, for genuine pathos and classic execution, to the Martyrdom of St. Stephen, on the head altar of the church of St. Stephen at Genoa.

Of Giulio's scholars and assistants, the most celebrated were F. Primaticcio, chiefly employed in the stuccoes and ornaments of the palace *del T.*; Benedetto Pagni of Pescaia, who accompanied Giulio from Rome to Mantua; and Rinaldo Mantovano, the most expert of the three, and in the opinion of Vasari, who laments the shortness of his life, the greatest painter that Mantua ever produced: the altar-piece

of Sta. Agostina alla Trinita has a grandeur of style above his age, and has by some been suspected to be the design of Giulio. To these may be added Fermo Guifoni, who coloured in the cathedral the Cail of St. Peter and St. Andrew, from the most studied and most beautiful cartoon of the master; and Theodore Ghigi, or as he subscribes himself, Theodore Mantovano, a great designer, and so practised in the style of Giulio, that after his death he was selected by the prince to finish several of his works.

In addition to his powers as a painter, Giulio Romano possessed a very considerable knowledge of the principles of architecture; and was employed in plans for several of the palaces at Rome and Mantua. His last architectural exertion was the erection of a splendid mansion for himself at Mantua. Vasari relates, that upon the death of San Gallo, the architect of St. Peter's, Giulio was selected by the pope for his successor, but was prevented leaving Mantua by the interest of the cardinal Duke, and the entreaties of his wife and her immediate friends and relations; and whilst he was endeavouring to surmount these difficulties, and enjoy the proffered honour and emolument, he was seized with illness, and borne to the grave in the year 1546, and in the 54th of his age. He left a son, called, after his respected master, Raphael, of whom nothing remains, but the tradition that he possessed talents worthy of his father. He died in 1560, at the age of 30. Fufeli's Pilkington.

ROMANO, in *Geography*, a town of Italy, in the department of the Adda and Oglio; 11 miles S.S.E. of Bergamo.

ROMANO, or *Ramano Cayo*, a small island off the N. shore of the island of Cuba; it is long and narrow, and lies at the E. extremity of the cluster of isles called the King's Garden.

ROMANO, *St.*, a town of Italy, in the department of the Panaro; 18 miles S.W. of Modena.

ROMANOV, a town of Russia, in the government of Jaroslavl, on the Volga; 16 miles W.N.W. of Jaroslavl. N. lat. 57° 46'. E. long. 39° 40'.

ROMANOVA, a town of Russia, in the government of Irkutsk, on the Angara; 60 miles W.S.W. of Ilimsk.—Also, a town of Russia, in the government of Tambov, on the Olonetz; 16 miles S. of Lipetzsk.

ROMANOVKA, a town of Russia, in the country of the Cossacks, on the Don; 116 miles E.N.E. of Azoph.—Also, a town of Russia, in the government of Upha; 64 miles N.E. of Orenburg.

ROMANOW, a town of Russian Poland, in the palatinate of Kiev; 8 miles N.E. of Zytomiers.—Also, a town of Austrian Poland, in Galicia; 33 miles W. of Przemyl.—Also, a town of Lithuania, called also Romanowo, in the palatinate of Novogrodek; 18 miles N. of Sluck.

ROMANS, a town of France, in the department of the Drôme, and chief place of a canton, seated on the Isere; two posts N.E. of Valence. The place contains 6173, and the canton 15,180 inhabitants, on a territory of 225 kilometres, in 11 communes. N. lat. 45° 2'. E. long. 5° 8'.

ROMANS, *Romant*, *Romanic*, or *Romance*, the polite language formerly spoken at the court of France; in contradistinction to the *Waloon*, or ancient Gaulish, spoken by the common people.

The Romans having subdued the Gauls, introduced part of their language among them; and a mixture of half Latin, half Gaulish, or Celtic, constituted the Romans; of which the modern French is only an improvement.

Hence, to *enromance* was to write in romance, &c. See ROMANCE.

Covarruvias, a learned Spanish writer, observes, that the name

name romance is general, and belongs alike to the Tuscan, French, and Spanish; inasmuch as all these were derived from the purity of the Latin tongue, which the Romans, being conquerors, introduced into these provinces, and which, at first, the nobles spoke and wrote. He further says, that the Latin tongue, being admitted into Spain, was spoken as in Rome, and that there were men well skilled in it, who spoke and wrote it with greater refinement than the vulgar; but upon the irruption of the Goths it was remarkably corrupted: that which was before *Roman* was converted into *Romance*, which is equivalent to its being derived from the Romans. And it farther appears, that the name *Romance* was given to the Spanish language, to distinguish it from the Gothic.

Mr. Planta, in his elaborate account of the Romansh language (Phil. Transf. vol. lxxvi. part i. p. 129, &c.), which is now spoken in the most mountainous parts of the country of the Grisons, near the sources of the Rhine and the En, informs us, that this language consists of two principal dialects; which, though partaking of the same general name, differ so widely as to constitute in a manner two distinct languages. One dialect, he says, which is spoken in the Engadine, a valley extending from the source of the En to the frontiers of the Tyrolese, is by the inhabitants called *Ladin*. And he observes, that the Romansh has never been used in any regular composition in writing, till the sixteenth century, nor affected by any foreign invasion, or intimate connection: but that it is at present the identical language that was spoken two hundred years ago.

This learned writer observes, that notwithstanding the variety of conjectures and controversies, which have occurred with regard to the Gallic Romance, it is agreed on all hands, that the vocabulary of the Roman, and the idiom of the Celtic, have chiefly contributed to its formation; and, therefore, that it partakes of a common origin with that of the Grisons. He adds, that there are incontestible proofs that this language was once universal through France, and that this, and not immediately the Latin, hath been the parent of the Provençal, and afterwards of the modern French, the Italian, and the Spanish.

From a comparison of the two Romances, as well as from the similarity of their origin, Mr. Planta infers, that they are one and the same language.

However, whilst the Grisons neglected to improve their language, or had no opportunity for this purpose, the taste and fertile genius of the troubadours, fostered by the countenance and elegance of the brilliant courts and splendid nobility of Provence, did not leave theirs long in the rude state in which we find it in the ninth century. But the change being gradual, and almost imperceptible, the French historians have fixed no epocha for the transition of the Romance into the Provençal. Nevertheless, it appears, that the former language had received no considerable alteration in the twelfth century, and it still bore the same name. But after this era, though the name occurs, the language distinguished by it is very different from the Romance of the ninth century. Allowing, however, the universal use of the Romance all over France till the twelfth century, and that what the writers of those times say of the Gallic, is to be understood of the Romance, of which there is sufficient evidence, it follows, says Mr. Planta, that the language introduced into England under Alfred, and afterwards more universally established by Edward the Confessor, and William the Conqueror, must have been an emanation of the Romance, very near akin to that which is now spoken in the Alps.

According to Du-Cange, the Romance had also penetrated

into Scotland before the twelfth century. The same corruption, or coalescence, which gave rise to the Gallic Romance, and that of the Grisons, must also have produced, in Italy, a language much resembling, if not perfectly similar, to those two idioms. It appears also, from what has been already said, that the language of the Romans penetrated very early into Spain, and that the Romance was very common in that kingdom. The universality of the Romance in the French dominions, during the eleventh century, accounts for its introduction into Palestine, and many other parts of the Levant, by Godfrey de Bouillon, and other adventurers, who engaged under him in the crusades.

This writer farther adds, that the heroic achievements and gallantry of the knights of the Cross gave rise to a swarm of fabulous narrations, which, though not an invention of those days, were yet, from the name of the language in which they were written, ever after distinguished by the appellation of Romances. And he presumes, that the Romance hath been preserved so near its primitive state, not only in the country of the Grisons, but in several other remote and unfrequented parts.

Mr. Berington, in his "Literary History of the Middle Ages," recently published, observes, that the language afterwards known by the name of French, was divided into two dialects, both of which bore the name of "Romance," or Romance, because each was formed on the basis of the Roman: that to the north being adulterated by a mixture of Frankish and Norman words; whilst the dialect of the south was vitiated by words transferred from the language of the Ostrogoths, Visigoths, and Alani. The river Loire, not rigidly taken, was their common boundary. The first might be called the "French Romane," the latter the "Provençal," because it was spoken by the subjects of Raimond, count of Provence, well known in the armies of the crusaders. The characters of these dialects, however, though owning a common source, were marked by strong lines of difference. The Provençal, from a milder climate, from a more constant intercourse with strangers, and from a closer affinity to the mother tongue, was soft and harmonious: the French more harsh, as retaining more of its northern mixture. But if we mention the countries in which these languages were current in the 13th century, it will be seen that the Provençal was confined within the limits above assigned it; while the French Romane, overflowing its natural boundaries, became familiar to distant nations. It passed with the conquerors into England, where it was previously fashionable. The Norman settlers rendered it familiar at Naples and in Sicily; though here it was soon vanquished by the superior fascination of the Italian dialect. The crusaders carried it into the East, and planted it in Syria, in Palestine, in Cyprus, and at Constantinople, where it was at least as permanent as the conquests which they had made.

ROMANTRINO, in *Geography*, a town of Italy, in the Novarese; 4 miles E.N.E. of Novara.

ROMANUS I., LECAENUS, in *Biography*, emperor of the East, rose from an obscure origin to various employments under Leo the philosopher, and was, at one time, possessed of the command of the naval armies. Having rendered himself all-powerful at court, he persuaded the prince Constantine to marry his daughter, banished the empress-mother Zoe to a monastery, and in 919 caused himself to be crowned emperor by the patriarch. He associated his three sons in the imperial authority, and ordered their names, with his own, to be placed in all edicts before that of the lawful emperor Constantine. The adherents of the latter made some attempts to free him from this servitude, but they

were frustrated and punished. During these intestine disturbances, Simeon, king of Bulgaria, renewed his inroads on the empire, and penetrated to the gates of Constantinople. Romanus brought him to accede to terms of peace, and the Roman admiral, about this time, entirely destroyed a Saracen fleet in the harbour of Lemnos. Simeon dying in 927, his son Peter refused hostilities, and broke into the Constantinopolitan territory, but peace was concluded, and a marriage entered into with the emperor's grand-daughter to the Bulgarian king. An invasion of the Roman dominions in Asia by the Syrian Saracens was repulsed by the imperial general; and the commanders of the armies of Romanus had equal success against the Russians, who had ravaged the empire with a numerous fleet. In the mean time, Romanus lost his eldest son Christopher, and the two remaining brothers quarrelled with each other, and with their father. The youngest son of Romanus formed a conspiracy for his father's dethronement, and in December 944, his apartment was entered by night, and he was conveyed to an island of the Propontis. He there assumed the religious habit and life, and died in 946 in this retreat, a true penitent for the injustice which he had inflicted upon Constantine. Previously to his decease, his two sons were banished to the same island, whom he reproached, when he met them on the beach, for their ingratitude and unkindness to him, nevertheless he very readily allowed them to share of his water and vegetable diet. Lecapenus does not appear, says Gibbon, to have possessed either the virtues or vices of a tyrant. The spirit and activity of his private life dissolved away in the sun-shine of the throne; and in his licentious pleasures, he forgot the safety both of the republic and of his family. Of a mild and religious character, he respected the sanctity, the innocence of youth, the memory of his parents, and the attachment of the people. *Univer. Hist. Gibbon.*

ROMANUS II., called *the Young*, succeeded his father, Constantine Porphyrogenitus, in 959. He had married Theophano, a woman of mean origin, who was charged with having been chiefly instrumental in the alleged crime of poisoning his father. Romanus was supposed to possess considerable talents, but he was habitually attached to frivolous amusements and dissolute pleasures, and resigned all care of the state to his chief chamberlain. In the morning, this luxurious emperor visited the circus; at noon he feasted the senators; the greatest part of the afternoon he spent in the tennis-court, the only theatre of his victories; from thence he passed over to the Asiatic side of the Bosphorus, hunted and killed four wild boars of the largest size, and returned to the palace, proudly content with the labours of the day. He banished from court his mother Helena, and his two sisters, who were reduced to a state of great indigence.

During the short reign of this emperor, the two brothers, Nicephorus Phocas and Leo, obtained great successes against the Saracens in Crete and the East, while the emperor was wasting his time in indolence. According to some historians, debauchery, but according to others, the evil practices of Theophano, brought his life to a close in the year 963, at the age of twenty-four, and in the fourth year of his reign. *Univer. Hist. Gibbon, vol. ix.*

ROMANUS III., named *Argyrus*, a patrician of an ancient family, was nearly related to Constantine IX. During the last illness of that emperor, he was offered his daughter Zoe for a wife, with the title of Cæsar. He would readily have declined the high honour intended for him, but was told the loss of his eyes or his life must be the consequence of his refusal. His wife, devoted to his welfare, as well as ardently attached to his person, made way for a new marriage, by retiring herself to a convent, and in 1028 Romanus espoused

the princess Zoe. On the death of Constantine he succeeded to the imperial throne, and began his reign by easing the people of some of their taxes, and performing other popular acts. In the second year of his reign, the Saracens having invaded Syria, the emperor resolved to march in person against them, but he was defeated, with the loss of his baggage, and a great part of his army. After his return, several public calamities in the empire followed, which occasioned him entirely to apply his mind to works of piety. In the mean time the empress Zoe, who, at an advanced age, continued to follow a licentious course of life, attached herself to a new lover of mean birth, whom she wished to raise to the purple, and she justified the Roman maxim, that every adulteress is capable of poisoning her husband. To effect her purpose, she caused the deadly cup to be administered to her husband; and finding it too slow in its operation, she employed an assassin, who suffocated him in the bath. He died in 1034, after a reign of five years and a half. *Gibbon. Univer. Hist.*

ROMANUS IV., named *Diogenes*, a descendant of Romanus Argyrus, in the regency of Eudocia, widow of Constantine Ducas, engaged in a conspiracy for raising himself to the throne, for which he was tried and condemned to death. This punishment, on account of his fine person, was commuted for a short exile, after which the imperial widow nominated him to the command of her armies, and in 1067 she married him, and he was proclaimed emperor. He had not occupied the throne more than two months, before he put himself at the head of the few troops he could assemble, and crossed the Hellespont to attack the Turkish sultan, who had made incursions into his territories. He came up with the Turks, who were retiring loaded with rich spoils. He attacked and routed them with great slaughter, and pursuing his blow, recovered Aleppo and Hierapolis. In the two following campaigns, Romanus displayed his military talents to great advantage, and finally drove the Turks across the Euphrates. In the fourth campaign he led a numerous army to the deliverance of Armenia. After this he shared in defeat, and was, in a general engagement, left alone, almost in the midst of his enemies, and was taken prisoner by the Turkish sultan, who obliged him to sign an humiliating treaty, and then set him at liberty. During his misfortunes, a revolution was effected at Constantinople: Eudocia had been driven from the throne, and shut up in a monastery; and her eldest son, Michael Ducas, had been proclaimed emperor. Romanus was dethroned, and his eyes torn out with circumstances of so much cruelty that he soon died. This happened in 1071, after a reign of three years and eight months. *Univer. Hist.*

ROMANUS, pope, was elected to that dignity in the year 897, upon the expulsion of Stephen VI. and VII. Little is recorded of him: he is said by Platina to have annulled the acts of his predecessor, and, in particular, to have declared his proceedings against the corpse and memory of pope Formosus unjust and illegal. Romanus' dignity was of very short duration; he died before he had been in possession of it quite four months. *Bower.*

ROMAON, ST., in *Geography*, a town of Portugal, in the province of Beira; 19 miles S.S.E. of Viseu.

ROMBACH, a town of the duchy of Wurzburg; 2 miles N. of Hasfurt.

ROMBLON, or ROMBLINO, one of the smaller of the Philippine islands, about 30 miles in circumference. N. lat. 12° 40'. E. long. 121° 58'.

ROMBOUTS, THEODORE, in *Biography*, a native of Antwerp, and born in 1597, was a painter of very considerable merit. At first he studied under Abraham Jansens; but

but in his 20th year he went to Italy, and there began his career as an historical painter. He was patronized by the duke of Tuscany, and painted several large compositions for that prince, who honoured and rewarded him handsomely. On his return to Antwerp he found Rubens in possession of full fame; and soon perceived how difficult it was for him to meet with that degree of estimation at home which he had received abroad. A noble emulation, however, stimulated him to enter the lists with that great master; and though he certainly was not adequate to the combat, yet he exhibited considerable prowess, which even Rubens acknowledged.

As he died at the age of 40, his works are not numerous. The principal ones, among those executed after his return from Italy, were painted for the court-house of Ghent.

He likewise painted pictures of low subjects, such as mountebanks and their attendants, soldiers playing at cards, &c. &c.; which he did as pastime, or merely to acquire money, but they are not among his best performances. On the historical pictures he produced, his reputation rests for support, and is upheld to a considerable rank.

ROME, } in *Geography* and *History*. The

ROMAN EMPIRE, &c. } ancient city of Rome, situated on the river Tiber, in east longitude  $13^{\circ}$ , and about  $41\frac{3}{4}^{\circ}$  of north latitude, though in its origin one of the most humble of cities, was destined to become the capital of the largest empire in the ancient world. In modern history it has been famous for being the centre of an ecclesiastical tyranny, under which, for many centuries, the greater part of what may be denominated the civilized world was held in subjection. The city of Rome, without dispute, was founded by Romulus; but we may trace the origin of its inhabitants, that is, of the ancient Romans, to Æneas, the hero celebrated in Trojan story. When the Greeks became masters of Troy, Æneas, with the forces under his command, retired into the fortrefs, which, for some time, they defended with great bravery; but being at length compelled to yield, he conveyed away his gods, his father, wife, and children, and fled, with a numerous crowd of Trojans attached to him, to the strong places of mount Ida. Here, however, his enemies followed him, and he was obliged to negotiate a peace, the terms of which forced him to quit the Trojan territories altogether: the Greeks, on their part, engaged not to molest him in his retreat. Æneas accordingly equipped a fleet, in order to seek a settlement in some foreign land. The Trojan having crossed the Hellespont, arrived in the peninsula of Pallene, where he built a city, calling it, from himself, Æneia, and left in it a part of his followers. From thence he sailed to Delos, and thence to Cythera, where he erected a temple to Venus. He built another, to the same goddess, in Zacynthus, and in this island he instituted games, named "the races of Venus and Æneas." Wherever the Trojan hero went he left memorials of himself, and in the time of Dionysius these were still existing in the places already mentioned, and in many others, as at Leucas, Actium, Dodona, &c. which were accordingly regarded as indisputable proofs of the reality of Æneas' voyage to Epirus: and "that he came into Italy," says Dionysius, "we have the concurrent testimony of all the Romans; the ceremonies they observe in their sacrifices and festivals bear witness to it; also the Sibylline books, the Pythian oracles, and many other things that nobody can reasonably reject as fable."

Æneas first landed in Italy, after crossing the Ionian sea, at Cape Minerva, in Japygia; from thence he went to Drepanum in Sicily, to which place Elymus and Ægyptus, who had escaped from Troy a little before him, had brought a Trojan colony. Æneas augmented this colony,

by leaving a part of his own followers; and then crossing the Tyrrhenian sea, he bent his course for Italy. He gave the name of Palinurus to the cape at which he first landed, from one of his pilots, who died there. From this place he sailed to several other parts, till at length the Trojan prince, and his faithful attendants, finished their long voyages on the coast of Latium, a small territory on the east side of the river Tiber, which now contains a part of the present Campagna di Roma. Latinus was the king of the country, and the people of it were called Latins. Here Æneas and his followers undertook to raise a second Troy, hoping that they had arrived at the end of their adventures.

When Æneas arrived in Italy, Latinus was engaged in a war with the Rutuli, but his success was very doubtful: he accordingly assigned to Æneas and his followers a tract of land for their settlement, upon condition that they should join their arms to his against the Rutuli, who were to be considered as their common enemy. Æneas accepted the conditions offered, and complied with his engagement so faithfully, that Latinus reposed in him the most unbounded confidence, and gave him in marriage his only daughter, Lavinia, thus securing to him the succession to the throne of Latium; hence Æneas changed the name of his camp from Troy, and called it Lavinium, in honour of his wife. The Trojans followed the example of their leader, by making alliances with Latin families; so that in a very short time they became one nation, united by the closest bonds.

There was, however, a cause for considerable strife excited by this union: Turnus, nearly related to the queen, and who had been brought up by Latinus, had entertained hopes of having Lavinia for his wife; when, therefore, he saw that princess given to Æneas, he instantly joined the Rutuli; but in the first battle after this confederacy, both Turnus and Latinus were slain: the consequence of this was, that Æneas came into quiet possession of the kingdom of Latium, which he governed with great wisdom, and transmitted to posterity. His reign was, however, short; but during that period he established the worship of the gods of his own country, and to the religion of the Latins he added that of Troy. The two palladiums, which had been the protectors of that city, became the tutelary deities of Lavinium, and, in after ages, of the whole Roman empire. He introduced, likewise, the worship of Vesta, and appointed certain virgins, called, from her, Vestals, to keep a fire burning in honour of the goddess. Many other deities, who had been revered in Troy, became probably known to the Latins by means of Æneas, which might be the occasion of his being designated by the appellation of the *pious Æneas*. This hero was, at length, obliged to head the united forces of the Latins and Trojans against the Rutuli, who had formed an alliance with Mezentius, king of the Tyrrhenians. A battle ensued, which lasted till night, when Æneas, being pushed to the banks of the Numicus, which was a boundary of Lavinium, and being forced into that river, was unfortunately drowned. The Trojans had, however, address enough not only to conceal his body, but to pretend that, instead of his having been drowned, he was suddenly taken up to heaven, where, in the character of a deity, he was overlooking the conduct of his subjects: who, in honour of the newly-formed god, erected to him a temple, under the title of "Jupiter Indiges."

Upon the death of Æneas, he was succeeded by his son Euryleon, named also Ascanius and Iulus, who contended with Mezentius, and in the end obliged him to sue for peace, which was granted, upon condition that for the future the river Tiber should be the boundary between the Latin

and Etrurian territories. Ascanius was the son of Æneas by his first wife, and of him Lavinia, who was left pregnant by Æneas, began to be jealous, and retired to the woods, where she was delivered of a son, which, from the place of his birth, she named Silvius. Ascanius after a time discovered the place of Lavinia's retreat, and persuaded her to return; from this time he treated Silvius not only as a brother, but resigned to him the kingdom as his rightful inheritance, and built for himself a capital to a new state, which he called *Alba Longa*. After he had reigned twelve years in his new kingdom, Ascanius died, leaving a son, named Iulus, between whom and Silvius the right of succession lay, the latter being the son, and the former the grandson of Æneas. At length the two kingdoms were united under Silvius; and as a compensation to Iulus, he was appointed to sovereign power in matters relating to religion, a power which thenceforward continued in his family. Silvius was succeeded by thirteen kings of the same race, who reigned, it is said, though with no great probability, during a space of 400 years. Of these little certain can be known; one of them, it appears, was named Tiberinus, who engaged in a war which proved fatal to him; for, in a battle which was fought on the banks of the *Albula*, he was forced into that river and drowned, whence the river was afterwards named the *Tiber*, which appellation it has borne ever since. Agrippa succeeded Tiberinus, and after him Alladius reigned, who was followed by Aventinus, who left his name to a certain hill, in which he was interred. Procas, the successor of Aventinus, was father of Numitor and Amulius, and at his death he bequeathed the throne to Numitor. This prince was driven from the government by Amulius, who, to secure it for himself, murdered Ægeus, Numitor's only son, and forced his daughter, Rhea Sylvia, to devote herself to the worship of *Vesta*, by which she was obliged to perpetual virginity. Her virtue, it was feigned, was violated by the god *Mars*; the consequence of which was, that she was delivered of two sons, who were placed in a wooden trough, and sent floating down the *Tiber*. From this dangerous situation they were rescued by Faultulus, the king's shepherd, and suckled by his wife *Acca Laurentia*, who, for her want of good conduct, was named *Lupa*, a circumstance that gave rise to the fable of the twins having been suckled by a she-wolf.

Great care was taken of their education, and as they grew up they exhibited something in their appearance and behaviour, that denoted them to be above the common race of shepherds: and at length Faultulus disclosed to them their real descent, which inspired them with the ambition of doing something worthy of their high birth. They had already obtained the names of *Romulus* and *Remus*, and before they had arrived at the age of manhood they had taken part in a quarrel between Amulius and Numitor, in which the former was deposed and killed, and the latter placed on the throne of *Alba*. Numitor, in gratitude for their service, advised them to undertake the founding of a new colony; and to assist them in the project, he bestowed upon them those lands near the *Tiber* where they had been brought up, supplied them with all kinds of implements for breaking up the ground, and with slaves and cattle, and granted full liberty to his subjects to join them.

For the more speedily carrying on their work, it was thought proper to divide those who were employed in it into two companies, one under each brother; a circumstance which, however well intended, gave birth to two rival factions, which openly manifested themselves when the choice

was to be made of a place for the building of their new city, the one being for the mount *Aventine*, and the other for the *Palatine* mountain: disputes on the subject came at last to open hostilities, and *Remus* was killed. By what means his death happened is not certain; but according to *Livy* he was killed by the hand of his brother.

*Regal State of Rome.*—*Romulus*, being now at the head of the colony, applied all his talents to the rearing of the new city, which he proposed to call after his own name. He fixed upon mount *Palatine* for its situation, and performed all those ceremonies which were connected with the superstition of the *Etrurians*. As to the exact year of the foundation of *Rome*, there is a considerable disagreement among chronologers, but it is generally referred to 753 before the birth of *Christ*. When the city was finished, which probably consisted of about a thousand houses, or rude huts, the people, being assembled to make choice of a government most agreeable to their wishes, determined upon a monarchy, and resolved to take *Romulus* as their king. Being, unquestionably, a man of a vigorous mind, he immediately applied himself to the establishment of good order, and to the formation of certain rules or laws by which his subjects were to be bound. He assumed a habit of distinction for himself, appointed twelve lictors to attend him as guards, and divided his subjects into different ranks. The lands he distributed into three portions, one for the support of government; another for the maintenance of religion; and the third he divided into equal portions of two acres to each *Roman* citizen. After this he formed a senate, consisting of a hundred persons, afterwards increased to 200, chosen from among the superior class of the people, and from whom the *Patrician* families were descended. This assembly were not only to be judges in matters of small importance, but to debate and resolve upon such public affairs as the king proposed, and to determine them by a plurality of voices. The people at large were allowed to create magistrates, enact laws, and resolve upon any war in which the king should propose to engage. *Romulus* next proceeded to settle the religious affairs of his people, and he added many of the *Trojan* deities to those whom the aborigines, or *Italian* natives, already worshipped. He chose priests, instituted festivals, and laid the foundation of a regular system of religion.

After all that has been attributed to the political sagacity and talents of *Romulus*, it is probable that the great outlines of the first constitution had a natural foundation in the usages of barbarous nations; though many of his institutions, it will be readily admitted, bear the traces of a discerning and active mind.

The *Sabines* were the most formidable enemies of the early *Romans*; but after the death of *Romulus*, who reigned 37 years, *Numa*, a *Sabine*, was elected king. He was, in his own nature, formed for pacific measures, and a worshipper of the gods; he endeavoured to give his people the same character. To increase his influence, and render his government more powerful, he pretended to divine inspiration. As we have seen in some preceding articles, see *CALENDAR*, *NUMA*, &c. he reformed the calendar, divided the year into twelve months, following the course of the moon; and distinguished the days into those in which civil occupations might be carried on, and those that were to be devoted to religious purposes. The business of agriculture was lawful on the latter, as a religious duty. This wife prince reigned forty-three years; and was succeeded by

*Tullius Hostilius*, whose reign commenced in the year 670 B.C. His disposition was the reverse of that of *Numa*. He made frequent wars upon his neighbours; and alienated

the Sabines from the Romans, who became the most powerful of their enemies. Tullius reigned thirty-three years.

Ancus Martius, the fourth king of Rome, grandson to Numa, inherited his virtues, to which he joined the talents of a warrior. He greatly increased the population of Rome, by naturalizing the conquered states; and he built the port of Ostia, at the mouth of the Tiber. His reign continued twenty-four years. See ANCUS.

The fifth king of Rome, Tarquinius Priscus, a citizen of Corinth, noted for his great liberality and vast wealth, was victorious in his wars, and he adorned the city with works of utility and magnificence. Such were the CIRCUS, the CAPITOL, and the CLOACÆ, those immense common sewers which led to the belief that Rome had been built on the ruins of an ancient city of much greater magnitude. This king was assassinated in the 38th year of his reign; and was succeeded by

Servius Tullius, his son-in-law, who very much improved the city with useful edifices, and by extending its boundaries. He also made some new arrangements in the division of the citizens; of which we shall have occasion to say more under the biographical article *SERVIVS Tullius*. This king was assassinated, after a reign of forty-four years, by his own daughter Tullia, who had married Tarquinius, the grandson of Priscus, and who thus paved the way for her husband to ascend the vacant throne.

The government of this Tarquin was systematically tyrannical, and from his haughtiness he obtained the surname of *Proud*. By his ill conduct he at length roused the vengeance of the people against him, and they not only expelled the tyrant, but at one blow abolished the regal government at Rome. See TARQUINIUS.

The regal form of government subsisted 244 years, during which there were only seven kings, of whom two died violent deaths, and one was deposed. These circumstances throw a considerable degree of doubt on the authenticity of the Roman history, as the reigns of monarchs who die in the common course of nature cannot be averaged so high as thirty years, whereas, notwithstanding the violent deaths and deposition of three of the kings, the average length of their reigns is more than thirty-four years each. Besides, it is admitted that for the first five centuries after the building of Rome, there were no historians, and, according to Livy, almost all the ancient records were destroyed when Rome was taken by the Gauls.

At the period of the abolition of the regal government, the territory of the Romans was extremely limited. The chief use which they made of their victories was to naturalize the inhabitants of some of the conquered states, and so increase their population; thus their strength being always superior to their enterprises, they laid a solid foundation of their empire.

*Consular State of Rome.*—When the regal government was abolished, it was agreed to commit the supreme authority to two magistrates, who should be annually elected by the people from the Patrician order. To these officers they gave the title of consuls, a name, as it has been said, that was intended to designate the counsellors of the republic, rather than its sovereigns, though, in point of fact, their authority differed scarcely in any thing from that of kings. They had the supreme administration of justice, the disposal of the public money, the power of convoking the senate and assembling the people, raising the armies, and the right of making peace and war. Their authority was, however, limited to a year. The first consuls were Brutus and Collatinus, the husband of that Lucretia whose death had occasioned the revolution which destroyed the regal power.

Tarquin was, at this time, in Etruria, where he got two of the most powerful cities, Veii and Tarquinii, to espouse his cause. He had also numerous and powerful partizans at Rome, and a plot was contrived to open the gates to admit him. The conspiracy was discovered, and Brutus had the mortification to find his two sons in the number of conspirators. He felt it his duty to forget the affection of the parent, and to consider their cases as consul; he accordingly condemned them to be beheaded in his presence. This act of severe justice struck such terror into the Romans, that scarcely any person ventured to oppose the consul; and the efforts that were made to bring back monarchy, proved unsuccessful. To secure themselves against the assaults of every invader, the Romans formed an alliance with the Carthaginians, which subsisted 250 years. All precautions, however, that were used for the preservation of the tranquillity of the state, could not guard the people against the oppression of the nobility. The former soon found that they had only changed their masters, and embraced the mere shadow of liberty. They made heavy complaints; these were followed by acts of rebellion, which occurred about the year B.C. 498. Peace was restored by the creation of a dictator, a magistrate who was elected for the period of six months, and who was invested with absolute and unlimited authority. Lartius, nominated to this office, armed the lictors with axes, summoned the whole people to the public assemblies, and calling over the names, enrolled all such as he judged most fit for the service of his country, inflicting, without hesitation, capital punishment upon those who dared to resist the order.

The spirit of the people, though checked for a time, was not subdued; they again complained, remonstrated, and even rebelled; and Rome, for some years, was the scene of anarchy and sedition. At length the senate, alarmed by the idea of a general revolt, abated their former rigour, in some measure eased the burdens of the people, and secured their future interests by the creation of five new magistrates, called tribunes, who were to be elected annually by the people, whose persons were to be sacred, whose business it was to defend the oppressed, to pardon offences, to arraign the enemies of the people; and, when they judged it necessary, to stop, by their fiat, the whole machine of government.

The tribunes demanded, and obtained, two other magistrates to assist them, who were named Ediles, from the charge of the public buildings of the city being committed to them. From this era, which was about 493 years before the birth of Christ, the commencement of the popular constitution of the Roman republic may be dated.

The power of the tribunes soon rose to an unexpected height, and proved the source of perpetual dissensions in Rome. The nobles and patricians had still in view an aristocratical form of government, while the tribunes aimed at nothing short of a complete democracy, hoping thereby to increase their own power and influence. The tribunes prevailed, and Coriolanus, a patrician of inflexible virtue, was, in the year 491 B.C., banished. Encouraged by the success of the tribunes, Spurius Cassius Viscellinus, an ambitious patrician, aspired to the supreme power. To accomplish his purpose, he flattered the people by proposing the Agrarian law, which caused the most violent commotions in the state. His ambition was, in the end, punished with death, and from this time perpetual contentions and discords subsisted between the tribunes and patricians. The number of the former was increased to ten, and the people procured the right of electing them in an assembly convened by the tribes. From this period the supreme authority in  
the

the Roman republic may be considered as having passed completely from the higher order into the hands of the people.

Hitherto the Romans had no written laws. So long as the monarchy subsisted, the will of their kings was to them instead of laws: while the ancient usages, the decisions of the consuls and of the senate were founded, or supposed to be founded, on the principles of natural equity. To supply this defect in the government, the tribunes proposed an establishment of laws, to which, but with great reluctance, the senate assented. Commissioners were accordingly appointed to bring from Athens the laws of Solon, that such of them might be adopted as were suited to the existing constitution of the Roman republic. Ten persons were chosen out of the senatorial order to compose a code of laws from those of Greece, and from the ancient usages of Rome. This system was divided into twelve tables, fragments of which are still to be found in the history of that early period, and which are the basis of the great structure of the Roman jurisprudence. An acquaintance therefore with these ancient laws is deemed of importance. Even in the most flourishing times of the republic, they continued to be of the highest authority. Cicero passed upon them a very high encomium, and from him we learn, that to commit these laws to memory was an essential part of a liberal education. From the twelve tables the juriconsulti composed a system of judicial forms for the regulation of the different tribunals. The Decemviri were invested with all the powers of government; each decemvir presided in his turn a single day, and was during that period invested with sovereign authority, with its insignia the fasces. The other nine officiated solely as judges in the determination of law-suits, and the correction of abuses. An abuse, however, of the most flagrant nature, committed by Appius CLAUDIUS, (see his article,) the chief of their number, was destined to bring their office to an end. Prompted also by the ambition and artifices of this man, the whole body conspired against the public liberty, and even bound themselves by an oath to endeavour to make the government perpetual. The senators, the soldiers, and the people, roused by the tyranny of these usurpers, inflicted the punishment which their crimes so justly merited, and at the same time restored the consular and tribunitian power. This was in the year 449 B.C.

The scale of the people was daily acquiring weight at the expence of that of the highest order. There were however two barriers, which still separated the patricians and plebeians; the one a law, which prevented their intermarriage, and the other, the limitation of all the higher offices to the order of patricians. It was the object of the people to remove these restraints, because then the patricians and plebeians would be on an equality. The first, after a long contest, was agreed to by the senate. This concession stimulated the people to inflexible perseverance in their struggle for the latter. The senate sought a palliative by the creation of six military tribunes instead of consuls, of whom three were to be patricians, and three plebeians. This measure satisfied the people for a short time: the consuls were, however, soon restored. The disorders of the republic, and the frequent wars in which the country was engaged, had interrupted the regular survey of the citizens. This was remedied by the creation of two officers, under the title of Censors, 437 B.C. whose business was not only to make the census every five years, but to inspect the morals, and regulate the duties of the people. The dissensions continued with but little variation, and the people uniformly, as their last resource, refused to enrol themselves,

till overawed by the supreme authority of a dictator. To obviate the frequent necessity of this measure, which enforced but an unwilling obedience, the senate had recourse to the expedient of paying the soldiery, who before had served without hire, as was usual in other countries under the feudal system. To defray this expence, a tax was levied from every person in proportion to his means, and thus a fund was established for the maintenance of the army. The Roman system of warfare now assumed a new aspect. The senate always found soldiers at command, and the army was under its controul: the enterprises of the republic were more extensive, and its successes more signal and important.

One of the early effects of the new system was a war declared against the Veii, the proud rival of Rome, and its equal in extent and population. After a siege of several years their capital was taken by Camillus, and the Veian territory was added to the Roman empire, in the year B.C. 396. Their dominions, till now confined to the territory of a few leagues, was at this period rapidly extended, and the Romans were, from this circumstance, an overmatch for all their neighbours.

The glory, and other good effects of the conquest over the Veii, were more than overbalanced by the subsequent fatal catastrophe in a war with the Gauls, who, under the command of Brennus, invaded Italy, plundered Rome, and actually burnt it to the ground, B.C. 390. They then retired to their own country loaded with spoils. To the burning of the city, on this occasion, as we have before observed, the Roman writers attribute the loss of all the records and monuments of their early history. The city was speedily rebuilt, but the effects of this calamitous event were long felt. The neighbouring states combined to prevent the Romans from recovering their former power; "but," says the historian, "neither the united efforts of foreign enemies, nor intestine divisions, could ruin a city destined to be the mistress of the world." The Gauls in 367 returned to Italy, but they were no longer successful, and were forced to retreat with the utmost precipitation. About the same time a plebeian was raised to the consulship, and the offices of Prætor and Edile were created; the one to administer justice, and the other to inspect the temples and public places. In the mean time hostilities were carried on by the Romans against those provinces that refused to submit to their power, or who made the least attempt at revolt. The war with the Samnites, a hardy nation, who inhabited a large track of southern Italy, which began about this period, was continued for half a century: but its successful termination was speedily followed by the reduction of all the Italian states. In the course of this important war, the Tarentines, allies of the Samnites, fought the aid of Pyrrhus, king of Epirus, one of the most illustrious generals of his age. Pyrrhus landed in Italy with 30,000 men and a train of elephants, about the year 280 B.C. For a few years he was successful, but so soon as the Romans understood his mode of warfare, they became more than a match for him; and when he was making a last effort near Beneventum, he was totally defeated with the loss of 26,000 men. He then abandoned all further views to Italy, and returned with precipitation to his own country, 274 B.C. The hostile states submitted to the victorious power, and Rome, 480 years from its foundation, was now sovereign of all Italy. It may be observed, that the extent of their conquests was as much the effect of wise policy, as of power. They removed to Rome all the leading men of the principal conquered cities, admitting them into their tribes, and thus, in a measure, soothed the pride

pride of the vanquished, by giving them an apparent share in their own domestic government; while, in arranging the constitution of the cities themselves, they filled their magistracies with illustrious Romans, whose abilities and influence were fitted to command allegiance, respect, and attachment to the Roman government.

The command of the continent did not satisfy the Roman ambition. The Carthaginian state excited their jealousy, and the aid which it had granted to the Tarentines was the pretext for commencing hostilities. Sicily had long been considered as the granary of Italy, and in that island the Carthaginians possessed considerable settlements, and they were ambitious of acquiring its entire dominion. An obvious policy led the Romans to dispute with them this important acquisition, which gave rise to the Punic wars. Sicily was at first the theatre of war between these two nations, which was afterwards removed into Africa, and thence into Spain and Italy. We have however, under the words **CARTHAGE** and **CARTHAGINIANS**, entered so much at large into this subject, as to preclude the necessity of doing here more than adding a few lines to render the Roman history connected. For some time the event was doubtful, but in the year 242 B.C. the Carthaginians were constrained to sue for peace, which they obtained on hard and ignominious terms. Rankling under the disgrace, they soon repaired their losses, collected a numerous army, and entrusted the supreme command to **HANNIBAL**; see his article. In 218 the war was renewed and prosecuted with vigour. The Romans were defeated in several battles, and Rome itself threatened with instant destruction. The prudent and cautious Fabius, then appointed dictator, averted the impending blow. In the course of this second Punic war **Maffiniffa** declared in favour of the Romans; and **Syphax**, king of Numidia, took up arms against them. **Scipio**, the celebrated Roman general, who carried the war into Africa, defeated the combined forces of **Ardruhal** and **Syphax** in several battles, and Carthage in its turn trembled for its safety. **Hannibal** was recalled from Italy, and defeated with prodigious loss in the year B.C. 202, and peace was concluded between the Romans and Carthaginians in the following year.

Elated with success the most complete, the Roman ambition now exceeded all limits, and aspired at the domination of the whole world. War was proclaimed against **Philip of Macedon**, who was defeated by **Flaminius** in **Thessaly** in the year 197 B.C. and obtained peace by agreeing to pay a tribute. The subjection of Macedon portended the ruin of all the Grecian states.

**Antiochus**, king of Syria, surnamed the Great, by the persuasion of **Hannibal**, declared war against the Romans, but after three years he was under the necessity of imploring peace, and to accept of terms the most rigorous. The Asiatic war, however, in the event proved fatal to the Romans, whose habits and manners were corrupted by the vices which accompanied the luxury of the East. Previously to this, **Perseus**, the Macedonian monarch, refusing to submit to the conditions that had been imposed on his father, was attacked and defeated by **Paulus Æmilius**, and his kingdom, which had subsisted seven centuries, was reduced to the form of a Roman province.

The most frivolous pretexts were assigned as the causes of the third Punic war, in the year 149 B.C., which ended in the destruction of Carthage, long renowned for arts, opulence, and extent of dominion. Conscious of their utter inability to resist this formidable power, the Carthaginians, after a short contest, offered every submission to save their city, but the Romans insisted that

Carthage should be razed to its very foundation. Despair inspired this miserable people with courage: they determined to make one effort at least, and then, if necessary, to die in the defence of their altars and gods. The effort was in vain, and Carthage, in 146, was taken by storm, its inhabitants cruelly massacred, and the city burnt to the ground. In the same year, the ruin of Corinth, and of the Grecian states, was effected. Greece became a Roman province under the name of **Achaia**. Many other kingdoms shared the same fate, among which were **Numantia** and **Lusitania**. Thus, in the space of about a century, the Romans extended their conquests in Europe, Asia, and Africa.

“This,” says Mr. Tytler, “was the era of the dawn of luxury and taste at Rome, the natural fruit of foreign wealth, and an acquaintance with foreign manners. In the unequal distribution of this imported wealth, the vices to which it gave rise, the corruption and venality of which it became the instrument, we see the remoter causes of those fatal disorders to which the republic owed its dissolution.”

All dissensions between the senate and the people had been suspended during their victories and triumphs, but when they had no foreign enemy to contend with, they turned their weapons against themselves. Sentiments of honour and virtue among the great mass of the people were well nigh extinguished; and pride, luxury, and self-interest, succeeded to temperance, severity of life, and public spirit. **Tiberius** and **Caius Gracchus**, (see their articles,) beheld, with concern, the universal corruption of the state, and attempted to introduce those reforms that might bring back the people to the former habits of moral discipline. They, however, both fell victims to their zeal for the public good. The tumults which attended, or were subsequent to the exertions of these noble youths, were but the prelude to those civil disorders which followed in quick succession. The **Numidian** war, which commenced in the year 111 B.C., and which lasted five years, afforded many instances of the injustice, insolence, and venality of the Roman people. In this, **Jugurtha**, (see his article,) who fought to usurp the crown of Numidia by the most cruel means, obtained the friendship and aid of the Roman senate, who having been bribed for the purpose, declared him innocent of every crime of which he was charged, and decreed to him the sovereignty of half the kingdom.

About this time, 105 B.C. an immense body of fierce barbarians rushed, like a mighty torrent, from the northern regions of Europe, and threatened all before them with utter ruin and desolation. **Marius** alone was able to avert the impending destruction. He defeated the barbarians with great slaughter: but he fought and triumphed merely with a view of furthering his own ambition, which was soon proved to be unbounded. **Sylla**, an artful and aspiring patrician, jealous of the glory and popularity which **Marius** had acquired, boldly stood forward to oppose him. Factions were formed, and preparations made for the doubtful contest. The effects, however, of domestic animosities were suspended by the Social war, which was occasioned by the anxiety of the allied states of Italy to attain the rights of citizenship; but the immediate cause of the war was the murder of **Drusus** the tribune. This war, which ended in the concession of those rights to such of the confederates as should return peaceably to their allegiance, was followed by the more dreadful contest between the opposing factions of **Sylla** and **Marius**. **Sylla**, commanding in a war against **Mithridates**, the most powerful monarch of the East, was superceded, and recalled from Asia. He refused to submit to the order, and having founded his army, found it well disposed to support him

him in all his measures. "Let us march to Rome," they exclaimed with one voice; "lead us on to avenge the cause of oppressed liberty." Sylla readily listened to the cry, and led his conquering army towards Rome: they entered the city sword in hand; Marius and his partisans fled with precipitation, and Sylla ruled for a time triumphant. He sullied the glory of his victories by many acts of cruelty and barbarity; assumed the title and power of perpetual dictator in the year 82; and after massacring many thousands in cold blood, returned to the station of a private man. It should, however, be observed, that previously to this he had engaged personally in the Mithridatic war, and that during his absence, Marius returned to Italy, and joining his forces to those of Cinna, laid siege to Rome, and compelled the city to absolute submission. After a tremendous and unsparring massacre of all whom they regarded as their enemies, Marius and Cinna proclaimed themselves consuls, without the formality of an election, but Marius died within a very few days after this had happened.

The death of these rivals did not give peace to Rome: Lepidus aspired to succeed Sylla in his power, and Pompey, who was, by much, his superior in talents, cherished the same ambition. While Pompey was employed in the reduction of the revolted provinces of Asia, the conspiracy of Catiline threatened the entire destruction of Rome. It was, however, extinguished by the prudence, foresight, and patriotic zeal of Cicero. The next considerable candidate for popularity and sovereign power was Julius Cæsar, who in the reign of Sylla had been numbered among the proscribed. From the danger attached to his situation he had learned prudence; and while Pompey and Crassus were contending for the command of the republic, Cæsar, who, by attaching himself to either rival, would infallibly make the other his enemy, shewed his talents and wisdom by reconciling them, and thus acquiring the favour and friendship of both. They accordingly agreed to a partition of power, and hence the first triumvirate was formed. Cæsar was elected consul: and he had the command of four legions, and the government of Transalpine Gaul and Illyria. The death of Crassus, in an expedition against the Parthians, dissolved the triumvirate, and the others, Pompey and Cæsar, aspired, as rivals, to an undivided dominion. The term of Cæsar's government was near expiring, but to secure to himself that power which was the object of his ambition, he procured a proposal to be made in the senate by one of his friends, which had the appearance of moderation and justice, namely, that Cæsar and Pompey should either both continue in their governments, or both be deprived of them, as they were equally capable of endangering public liberty by an abuse of power. The motion passed, and Cæsar offered to resign, but Pompey refused, and resolved to maintain his right by force of arms; a civil war was the necessary consequence. The senate were chiefly attached to Pompey, but Cæsar had on his side a victorious army, consisting of ten legions, and the great body of the Roman citizens, whom he had won to his interest by his liberality. Mark Antony and Cassius, at that time tribunes of the people, left Rome for Cæsar's camp. The senate, apprehensive of his designs, and dreading the effects of his power and popularity, passed a decree, branding with the crime of parricide any commander who should dare to pass the Rubicon, a river which was the boundary between Italy and the Gauls, with a single cohort without their permission. Cæsar set at defiance their decree, and marched direct to Rome. Pompey, to whom the senate had committed the defence of the state, was without an army. He quitted Rome, followed by the consuls and a part of the senate, and endeavoured

hastily to levy troops over all Italy and Greece, while Cæsar had triumphantly entered the city, amidst the acclamations of the people, seized the public treasury, and possessed himself of supreme authority without any opposition. Having secured the capital, he set out to meet the lieutenants of Pompey, who had possession of Spain. He defeated them, and subdued the whole country in the space of forty days. On his return, he found he had, during his absence, been nominated dictator; and in the succeeding election he was chosen consul, and thus invested by a double title, with the right of acting in the name of the republic. Pompey had now raised a numerous army, and in the field of Pharfalia the rival armies met: Cæsar was victorious, leaving 15,000 of his enemies dead, while 24,000 surrendered themselves as his prisoners. The battle of Pharfalia, for so it has been named, which happened in the year B.C. 48, decided the fate of the rival chiefs, and that of the empire.

In the space of two years Cæsar gave law to the known world; but his success accelerated his ruin. He took part with Cleopatra against Ptolemy: a war ensued, in which Ptolemy was killed, and Egypt was subdued by the Roman arms. In this war the famous library at Alexandria was burnt to ashes. A revolt of the Asiatic provinces, under Pharnaces, the son of Mithridates, was signally chastised; and the report of the conqueror to the Roman senate was conveyed in three words, *veni, vidi, vici*. Cæsar having added Mauritania to the number of the Roman provinces, returned to Rome absolute master of the empire. It is, however, much to his credit, that from this moment his attention was directed solely to the prosperity and happiness of the people. He remembered no longer that there had been opposite parties: he was beneficent alike to the friends of Pompey as to those attached to himself. He laboured to reform every species of abuse and grievance: and in return he was hailed "the father of his country"—was created consul for ten years, and perpetual dictator. His person was declared sacred, and he had the title of *Imperator* bestowed upon him. Thus the Roman republic finally, by its own acts, resigned its liberties. A conspiracy was formed against him by sixty of the senators, at the head of whom were Brutus and Cassius, and the dictator was stabbed, in the year 44, at the foot of Pompey's statue. Mark Antony improved this favourable opportunity, and became master of the commonwealth: he found, however, a formidable competitor in Octavius, the grand nephew and adopted heir of Cæsar, who, at this critical moment, arrived in Rome, and who gained the senate to his interest. The contest terminated in a civil war, in the course of which Octavius and Antony were reconciled, and they strengthened their hands by admitting Lepidus into their association. Thus was formed the second triumvirate, the effects of whose union were beyond measure destructive. They divided among themselves the provinces, and cemented their union by a deliberate sacrifice, made by each, of his friends to the vengeance of his associates. Antony gave up his uncle Lucius to death; Lepidus his brother Paulus; and Octavius his guardian Toranius and his friend Cicero. Besides these illustrious characters, 300 senators and 3000 knights were put to death. A conspiracy was excited against the triumvirs. Octavius and Antony marched against them; an engagement ensued at Philippi, which decided the fate of the empire: the republican party was annihilated. Antony now sought a recompence for his troops by the plunder of the East. He became the willing conquest of Cleopatra, for whom he abandoned, and even forgot, glory, ambition, and fame. Octavius saw this phrenzy with delight, and contemplated in it his rival's ruin; and from Lepidus he had nothing to dread,

dread, whose insignificant character drew on him the contempt of his own friends, and whose folly, in attempting an invasion of the province of his colleague, was punished by his deposition and banishment. Antony had lavished the provinces of the empire, in gifts to his paramour and her children. At these enormities the Roman people were justly indignant, and the divorce of his wife Octavia, the sister of his colleague, was the signal of declared hostility between them. An immense armament, chiefly naval, came to a decisive conflict near Actium, on the coast of Epirus. Fortune was favourable to Octavius, and the battle of Actium gave him the empire of the world.

Thus have we traced the history of Rome from its commencement, through all its revolutions, till the final extinction of the republic: before we come to an account of the emperors, we shall notice some particulars relating to the character of the ancient Romans, beginning with the mode of their education, upon which almost every thing depends, with regard to character, in the largest extent of the word.

*Roman Education and Literature.*—A rigid severity of manners was the characteristic of the Romans under their kings, and in the first ages of the republic. The private life of the citizens, which was frugal, temperate, and laborious, had its influence on their public character. The head of every family had sovereign authority over all the members that composed it, and this power, there is every reason to believe, was seldom, if ever, abused. The Roman laws did not prescribe a system and rules for the education of the young, but the manners of the people supplied this want, and the utmost attention was bestowed on the early formation of mind and character. The Roman matrons did not abandon their infants to mercenary nurses. They esteemed those duties connected with the nurture of their offspring and the rudiments of their education as the highest points of female merit. A remarkable degree of attention was paid to the language of children, and to the attainment of correctness and purity of expression; thus, the Gracchi, the sons of the virtuous and excellent Cornelia, were said to be educated “non tam in græmio, quam in sermone matris.” This was the more necessary, because it was by eloquence more than by the exercise of any other talent that the young Roman could rise to the highest offices and dignities of the state. The exercises of the body were likewise particularly attended to, and whatever had a tendency to harden the temperament, and to confer strength and agility, was regarded as of prime importance. At seventeen a youth was consigned to the care of a master in rhetoric, whom he attended constantly to the forum, or to the courts of justice, for it was necessary to be an orator, to be regarded as an accomplished gentleman.

Before the intercourse with Greece, which took place after the Punic wars, the Roman people were rude and illiterate, and it was not till five hundred years had elapsed, that the regular drama was introduced at Rome, and the earliest Roman plays were, no doubt, translations from the Greek. Of the early Roman drama, Ennius was a great ornament, and from his time the art made a rapid advancement. The comedies of Plautus, the contemporary of Ennius, display much knowledge of human nature, and are still read with pleasure. Cæcilius improved so much on the comedies of Plautus, that he is mentioned by Cicero as, perhaps, the best of the Roman comic writers, but none of his compositions remain. The “*Andria*” of Terence, the first of his comedies, was performed in the year 587 from the building of the city. The comedies of this writer are chiefly borrowed from the Greek of Menander and Apollo-

dorus, and their merit lies in that nature and simplicity which are observable in the structure of the fable; in the delineation of the characters, and in the delicacy and purity of the sentiments. The Roman comedy was of four different species; the *first* admitted serious scenes and personages; the *second* was a representation of ordinary life and manners; the *third* was where the dialogue was not committed to writing, but the subject of the scene was prescribed, and the dialogue was filled up by the talents of the actors: and the *last* included pieces of comedy of the lowest species; farces, or entertainments of buffoonery. The Roman tragedy kept pace in its advancement with comedy; of the best, namely, of Actius and Pacuvius, there are no remains; those under the name of Seneca are probably the work of different hands.

The most perfect era of Roman literature was the age of Cicero, comprehending all, of the preceding times, whom Cicero might have seen, and all, of the succeeding, who might have seen him. These will include, among others, Sallust, Cæsar, Livy, and Tacitus, as historians. Among the poets were Lucretius, Catullus, Virgil, Horace, Ovid, Tibullus, and Martial. See the several articles in the alphabetical arrangement of the New Cyclopædia.

*State of Philosophy and the Arts among the Romans.*—In the earlier periods of the republic, the Romans had little leisure to bestow on the cultivation of the sciences, and had no conception of philosophical speculation. It was not till the interval between the war with Perseus and the third Punic war, that philosophy made its appearance at Rome. Some learned Achæians, banished from their country, had settled in various parts of Italy, and applied themselves to the cultivation of literature, and the education of youth, diffusing a taste for those studies hitherto unknown to the Romans. Jealous of the introduction of foreign manners with foreign studies, the senate banished the Greek philosophers from Rome. But Carneades and Critolaus came afterwards in the train of an Athenian embassy, who revived the taste for the Greek philosophy, and left behind them many able disciples who publicly taught their doctrines. As the Roman manners had still a tincture of their ancient severity, the Stoical system prevailed. The philosophy of Aristotle was little known in Rome till the age of Cicero, and even then the great orator complains that Peripatetic philosophy was but little understood at Rome, and, on that account, he sent his son to study its doctrines in the schools of Athens. Lucullus, whose residence in Greece gave him an opportunity of being acquainted with all the different sects, disseminated, on his return to Rome, a very general taste for philosophy. The old and new academy had each their partisans; of the former, the most illustrious disciples were Marcus Brutus and Terentius Varro. Cicero, who must be deemed the most eminent of all the Roman philosophers, is usually classed among the supporters of the new school.

The cultivation of physics, or natural philosophy, seems to have been but little attended to, either by the Greeks or Romans. The natural history of Pliny is the most valuable storehouse of the knowledge of the ancient in physics, economics, and the arts and sciences. The Romans had no natural taste in the fine arts. On the conquest of Greece, an immense field opened at once to their eyes, and they were almost instantly surrounded with the master-pieces of art; but their minds were not sufficiently cultivated to appreciate their excellencies.

The Romans seem to have invented or perfected no art, but that of war. The rest they had from Egypt, Greece, Sicily, and Etruria. In our articles, therefore, concerning

the *Musick of the Ancients*, and *Musical Instruments* of the Greeks, (see MUSIC, and INSTRUMENT, in *Musick*.) those of the Romans are generally included. They, indeed, imitated and adopted many customs, religious rites and ceremonies of the Etrurians; and Plutarch (*Vita Romuli*) mentions it as a prevailing opinion, that the Greek language, which was spoken by the Romans in the time of Romulus, was not corrupted by Italian words. From these accounts it appears that the Romans had not only vocal and instrumental music as well as other arts and sciences from Greece, but even their alphabet, language, religion, and all the learning of which they were possessed during the time of their kings, and the first ages of their republic, these having been originally Greek, though the Romans had them through Etruscan strainers.

The first Roman triumph, according to Dionysius (lib. ii.), was that of Romulus over the Cæmentes; in which, clad in a purple robe, he was drawn in a chariot by four horses. The rest of the army, both horse and foot, followed, ranged in three several divisions, hymning their gods in songs of their country, and celebrating their general with extemporary verses: this account affords a very venerable origin to the improvisatori of Italy; as the event happened in the fourth year of Rome, 749 years before Christ, and the fourth year of the seventh olympiad.

Indeed the Romans were later in cultivating arts and sciences than any other great and powerful people; and none of them seem to have been the natural growth of the soil, except the military art; all others were brought in by conquest.

During the reign of Augustus, except Vitruvius, it does not appear that the Romans had one architect, sculptor, painter, or musician; those who have been celebrated in the arts at Rome, having been Asiatics, or European Greeks, who came to exercise such arts among the Latins, as the Latins had not among themselves; this custom was continued under the successors of Augustus, and those Romans who were prevented by more important concerns from going into Greece, contrived in a manner to bring Greece to Rome, by receiving into their service the most able professors of Greece and Asia, in all the arts. We find too, not only that each of the best Roman writers was an imitator of some great Grecian model, but are certain that the finest remains in painting, sculpture, and architecture, which still subsist in Italy, were either brought thither from Greece, or were the works of Greek artists, who had left their own ruined and oppressed country, to bask in the warm sunshine of power and affluence at Rome.

Vitruvius, in his *Treatise on Architecture*, has inserted a chapter on music, in which he has given the harmonical system of Aristoxenus; but he introduces it with a complaint of the unavoidable obscurity of musical literature, on account of the deficiency of terms in the Latin tongue, to explain his ideas. "The science of music, in itself obscure," says he, "is particularly so to such as understand not the Greek language." This writer, therefore, who seems to have been the first that had treated of music in the Roman language, confesses the necessity he was under of using Greek appellatives, not only for the notes, but for other parts of the art; which shews, if not the low state of music at Rome when he wrote, which was in the Augustan age, at least whence their music came; and *borrowing* implies *inferiority*. Indeed, the writings of Cicero shew that philosophy, and all the arts and sciences, were wholly furnished to the Romans from Greece, even in the most enlightened times.

Music was, however, in great favour at Rome during the latter end of the republic, and the voluptuous times of

the emperors; the stage then flourished; the temples were crowded; festivals frequent; and banquets splendid; so that we may suppose it to have been very much used both upon public and private occasions, in so rich, populous, and flourishing a city as Rome, the mistress of the world. But this music must have differed as little from that of the Greeks, as the descriptions of it in Horace and Virgil differ from those to be found in Homer, and the Greek lyric poets.

Notwithstanding the Romans had the Greeks, Etrurians, and Sicilians to imitate in the polite arts, they never advanced so far in them as the modern Italians have done; who, without any foreign help, have greatly surpassed not only their forefathers the ancient Romans, but even the Greeks themselves, in several of the arts, and in no one so much as that of music, in which every people of Europe have, at different times, consented to become their scholars.

From the success which attended the arms of the Romans, and that dominion which they acquired over the greatest part of the known world, it is natural to conclude that they must have carried the military art to a higher degree of perfection than any other nation of that period. It is the discipline of an army that makes the multitude act as one man; it moreover increases the courage of troops, because each individual confides in the steady co-operation of his associates. From the constant practice of athletic exercises, the Romans were inured from infancy to hardiness and fatigue, and bred to that species of life which a soldier leads in the most active campaign.

Among the ancient nations there were usually but two different arrangements of the troops in order of battle. The one the Phalanx, or close arrangement in parallelograms, intersected only by great divisions; the other the Quincunx, consisting of small companies or platoons, disposed in three straight lines, with alternate spaces between them equal to the space occupied by each company. The military tactics of the Romans are supposed to have been at their highest pitch of excellence during the Punic wars. Hannibal was a master in the science, and the Romans understood how to profit from the instructions of an enemy. The art of intrenchment was carried to great perfection by the Romans, particularly by Julius Cæsar. Their intrenchments consisted of a ditch from nine to fifteen feet in depth and width, fenced on the inside by the mound of excavated earth, and on the outside by strong stakes with pointed branches.

In besieging a town, several camps were formed around the place, joined to each other by lines of circumvallation and countervallation. A mound of earth was raised, gradually rising in elevation as it approached the city. The front, where workmen were employed, was defended by a curtain of hides. On this mound the engines of attack were advanced, till they played on the very spot which the besiegers wished to assail. The same machines were used by the besieged for annoying the enemy. When the batteries from the terrace had silenced those on the walls, the battering rams were brought up, and if it once reached the walls, it was generally decisive of the fate of the town. The great object, therefore, of the besieged, was to prevent its approach by every power of annoyance.

The naval military art was utterly unknown among the Romans till the first Punic war. A Carthaginian galley was the first model; and in the space of two months they equipped a fleet of 100 galleys of five banks of oars, and 20 with three banks. In the times of the empire, which we are going, very briefly, to describe, the Romans maintained their different conquests, not by their armies, but by their fleets, which were moored in the large rivers and bays,

and generally preserved a fixed station, as well as the legions.

*Rome under the Emperors.*—The battle of Actium, as we have already observed, decided the fate of the commonwealth, and Octavius, now having assumed the name of Augustus, was master of the Roman empire. This emperor new-modelled the state, flattered the people, and rendered monarchically supportable to republicans. Augustus possessed the talent of discerning what character was best fitted for gaining the affections of the people he governed, and versatility of temper and genius to assume it. His virtues, though the result of policy, not of nature, were certainly favourable to the happiness, and even the liberties, of his subjects. The fate of Cæsar might, and probably did, warn him of the insecurity of an usurped dominion; and, therefore, while he studiously imitated what was excellent in his predecessor, he affected a much higher degree of moderation and respect for the rights of the people. Long peace, in which the temple of Janus was shut, which had been open nearly two centuries, since the beginning of the second Punic war; an uniform and temperate government, and prevailing luxury, introduced a slow poison into the vitals of the empire. The national character was changed. The outward form remained; but the animating spirit and vigour had vanished. The Romans thought themselves free, because they had no longer to fight for their liberty. The sovereign kept up the delusion, by maintaining the ancient forms of the republican constitution, in the election of magistrates, &c. though they were nothing more than mere forms. He even pretended to consider his own functions as temporary, exerted for the benefits of the people, and depending upon their will. Five times, in the course of his protracted reign, did he submit to a sort of election. The emperor reposed the most unlimited confidence in Mecenas, by whose counsels all public affairs were conducted, and the most salutary laws enacted for the remedy of public grievances, and even the correction of the morals of the people. By his influence and wise instructions, Augustus assumed those virtues to which his heart was a stranger; and which, in their tendency to the happiness of his subjects, were equally effectual as if they had been the genuine fruits of his nature. On the death of Marcellus, the nephew and son-in-law of the emperor, he bestowed his chief favour on Marcus Agrippa, who married Julia, the widow of Marcellus; and on his decease, Julia took Tiberius for her third husband, who became the emperor's son-in-law by a double tie, for Augustus had previously married his mother, Livia. On the death of the emperor, in the 14th year of the Christian era, and in the 44th of his reign, Tiberius succeeded to the throne.

The government established by Augustus, founded, as it unquestionably was, on the power of the sword, not on the consent of the senate and people, degenerated in proportion as the army became corrupted. This prince had resolved to confine the boundaries of the empire to the limits which, he assumed, Nature had pointed out, *viz.* on the west the Atlantic ocean; the Rhine and Danube on the north; the Euphrates on the east; and towards the south, the sandy deserts of Arabia and Africa. His immediate successors adopted this resolution. Britain and Dacia were the sole accessions to the empire during the first century of the Christian era. A military spirit was, in some degree, preserved and cherished, when almost every virtue was extinguished; but the discipline of the legions was greatly corrupted by the ambition, or relaxed by the weakness, of the emperors, who confided in the army, and particularly in the strength and fidelity of the Prætorian guards, which

had been formed by Augustus, and were kept up for the protection of the emperor's person. The soldiers were, however, soon roused to a sense of their own power, and of the impotency of the civil authority.

Tiberius, the second emperor, was an unfeeling tyrant, and he took for his counsellor Sejanus, prefect of the Prætorian guards, a man still more cruel and tyrannical than himself. Sejanus conceived the project of placing himself on the throne: for the furtherance of his plans, he caused Drusus, the son of the emperor, to be poisoned, and removed from the sight of the people the sons of Germanicus, who were the natural heirs to the crown. He even persuaded Tiberius himself, under the pretence of a discovery of plots for his assassination, to retire from Rome to the isle of Capræ, and devolve the government upon himself. He had but one step more to the attainment of the object of his ambition: he was on the point of assassinating his master when he was detected, and instantly executed. Tiberius now became negligent of the cares of government, and the imperial power was displayed only in scenes of cruelty and rapine. At length he fell sick, and was strangled in his bed by Macro, the prefect of the Prætorian guards, in the 78th year of his age, and the 23d of his reign.

Caligula, the son of Germanicus, who was Tiberius's nephew, was the third emperor of Rome. The commencement of his reign was signalized by a few acts of clemency and good policy. But tyrannical and cruel by nature, he substituted military execution for legal punishment. The provinces were loaded with the most oppressive taxes, and daily confiscations filled the imperial coffers. He was assassinated in the 4th year of his reign, and was succeeded by his uncle

Claudius, the son of Octavia, the sister of Augustus, whose short reign, though he was a man of weak intellects, and of little education, was marked by an enterprise of importance. He undertook the reduction of Britain, and after visiting the island in person, left his generals, Plautius and Vespasian, to prosecute a war, which was carried on for several years with various success. The inhabitants of Wales, then denominated the Silures, under their king Caractæus, made a noble resistance, but were finally defeated, and Caractæus was led captive to Rome. The civil administration of Claudius was weak and contemptible; he was the slave even of his domestics, and the dupe of his abandoned wives Messalina and Agrippina. Claudius was put to death in the 15th year of his reign.

Nero, the scourge of mankind, succeeded his father Claudius, and for the first five years he reigned with great applause, whence Trajan, said "cunctos principes longè abesse a Neronis quinquennio;" but when his character began to unfold itself, he was found to be a compound of every thing that was base and inhuman. (See his article.) He perished in the 30th year of his age, and the 14th of his reign.

The two succeeding emperors, Galba and Otho, did not reign a year between them; the former was murdered by the soldiers, and the latter died by his own hand.

The reign of Vitellius, the next emperor, was of eight months' duration. He is said to have proposed Nero for his model, and it was just that he should resemble him in his fate. Vespasian, who had obtained from Nero the charge of the war against the Jews, which he had conducted with ability and success, was proclaimed emperor by his troops in the East, and a great part of Italy submitting to his generals, Vitellius capitulated to save his life; but as soon as Rome was taken, the deposed emperor was seized, massacred, and his body thrown into the Tiber.

Vespasian reigned with great popularity for ten years.

He respected the ancient forms of the constitution, restored the senate to its deliberative rights, and acted by its authority in the administration of all public affairs. Under his reign, and by the arms of his son Titus, was terminated the war against the Jews. They had been brought under the yoke of Rome by Pompey, who took Jerusalem. Under Augustus, they were governed for some time by Herod as viceroy; but the tyranny of his son Archelaus was the cause of his banishment, and also of the reduction of Judæa into the ordinary condition of a Roman province. In the reign of Vespasian, Jerusalem was besieged, and after a blockade of six months, taken by storm, the temple burnt to ashes, and the city buried in ruins. Vespasian associated Titus in the imperial dignity, and soon after died, at the age of 69, in the year 79 of the Christian era.

In elective monarchies, the vacancy of the throne is a moment big with danger and mischief. The Roman emperors, desirous to spare the legions that interval of suspension, and the temptation of an irregular choice, invested their designed successor with so large a share of present power, as should enable him, after their decease, to allume the remainder, without suffering, as it were, the empire to perceive the change of masters. Thus Augustus, after all his fair prospects had been snatched from him by untimely deaths, rested his last hopes on Tiberius, and obtained a law, by which the future prince was invested with an authority equal to his own over the provinces and the armies. Thus, also, Vespasian subdued the generous mind of his eldest son. Titus was adored by the eastern legions; his power was dreaded; but as his virtues were clouded by the intemperance of youth, his designs were liable to be suspected. Instead of listening to such unworthy suspicions, the prudent monarch associated, as we have seen, Titus to the full powers of the imperial dignity: and the grateful son ever approved himself the humble and faithful minister of so indulgent a father.

Vespasian had embraced every measure that might confirm his recent and precarious elevation. The military oath, and the fidelity of troops, had been consecrated by the habits of an hundred years to the name and family of the Cæsars; and although that family had been continued only by the fictitious rite of adoption, the Romans still revered, in the person of Nero, the grandson of Germanicus, and the lineal successor of Augustus. It was not without reluctance and remorse that the Prætorian guards were persuaded to abandon the cause of the tyrant. The rapid downfall of Galba, Otho, and Vitellius, taught the armies to consider the emperors as the creatures of their will, and the instruments of their licence. The birth of Vespasian was very mean: his own merit had raised him, in an advanced age, to the empire. "Such a prince," then, says Gibbon, "consulted his true interest by the association of a son, whose more splendid and amiable character might turn the public attention from the obscure origin, to the future glories, of the Flavian house. Under the mild administration of Titus, the Roman world enjoyed a transient felicity. His character was humane, munificent, dignified, and splendid. In his reign happened that dreadful eruption of Vesuvius, which overwhelmed the cities of Herculaneum and Pompeii; and the public losses from these calamities he repaired by the sacrifice of his fortune and revenues. He died in the third year of his reign, and obtained the most exalted epithet, 'Delicæ humani generis.'"

Domitian, the brother of Titus, and suspected of murdering him by poison, succeeded to the empire A.D. 81. He was a most cruel tyrant. A rebellion in Germany gave him an opportunity to signalize the barbarity of his disposi-

tion; and its consequences were long felt in the sanguinary punishments inflicted under the pretence of justice. In this reign, the successes of Agricola in Britain threw a lustre on the Roman arms; nevertheless Domitian treated this brave commander with the basest ingratitude. The emperor was assassinated in the sixteenth year of his reign.

It may not be amiss, before we proceed, to notice, in a geographical sense, the different divisions of the empire under Augustus, and which continued during the reigns of the twelve Cæsars, to that of Adrian. When Augustus made himself master of the Roman empire, its possessions extended almost to all the then known world. He did not, as we have seen, make any attempts to extend the limits of the empire, but took every means, that his great talents could suggest, to preserve his own authority, without rendering the senate and people his enemies. He appeared to surrender to them their ancient authority and rights, and only to attend to those parts of the government which were most laborious and difficult. He even seemed to divide the provinces of the empire between himself and the nation, which provinces he arranged into twenty-six dioceses or departments. Of these he granted twelve to the senate and people, reserving to himself the other fourteen. He had taken care, in this division of the empire, that not only the most considerable provinces should fall to his own share, but that they should be so situated, as to give him a decided pre-eminence over the others. With respect to the departments under the controul of the senate and people, two were governed by proconsuls, and ten by pretors.

I. The two departments governed by proconsuls comprehended Africa, including Africa proper, Numidia, and part of Libya.

II. The ten departments under the government of pretors comprehended that part of Spain denominated Bætica; Gallia Narbonensis; Sicily; Sardinia, and Corsica; Illyria, and part of Epirus; Macedonia, and part of Greece; Achaia; Bœotia, Acarnania, and part of Epirus; the island of Crete; Cyrenaica, an ancient kingdom of Africa, including the present kingdom and desert of Barca and Tripoli; the island of Cyprus; Bithynia; Paphlagonia; the countries about the Propontis and Pontus.

III. The fourteen dioceses or departments under the immediate authority of the emperor were as follow: Hispania; Lusitania; Celtiberia; Aquitania; the most important parts of Gallia and Belgica; Nerica, Vindelicia, and Rhætia; Mœsia, comprehending Dardania, Dacia, and Thrace; Dalmatia, and part of Illyria; the Maritime Alps; Cilicia, Iauria, and Lycæonia; Galatia, Pamphylia, and Pisidia; Syria, Little Armenia, Mesopotamia, and all the eastern parts of the empire; Egypt, and part of Arabia; Italy, from the island of Sicily to the Alps.

Nerva, who succeeded Domitian, had scarcely accepted the sovereign power from the murderers of that emperor, before he discovered that he was too aged and infirm to stem the torrent of public disorders, which had multiplied to an alarming degree under the long tyranny of his predecessor. His mild disposition was highly respected by the virtuous, but was treated with great contempt by the guilty. Though he had relations of his own, yet he adopted for his successor a stranger, Trajan, who had commanded with wisdom and success a powerful army in Lower Germany, and immediately, by a decree of the senate, declared him his colleague and successor in the empire. Nerva died in sixteen months after his elevation to the throne.

Trajan possessed every talent and every virtue that can adorn a sovereign. As a warrior, he raised the Roman arms to their ancient splendour, and greatly enlarged the boundaries

boundaries of the empire. He subdued the Dacians, conquered the Parthians, and brought under subjection Allyria, Mesopotamia, and Arabia Felix. Nor was he less eminent in promoting the happiness of his subjects, and the internal prosperity of the empire. He was illustrious in every connection, and in every station of life, and obtained the epithet *Optimus*. He died after a glorious reign of nineteen years. Of this emperor Gibbon remarks, "It is sincerely to be lamented, that while we are fatigued with the disgusting relation of Nero's crimes and follies, we are reduced to collect the actions of Trajan from the glimmering of an abridgment, or the doubtful light of a panegyric. Above two hundred and fifty years after the death of Trajan, the senate, in pouring out the customary acclamations on the accession of a new emperor, wished that he might surpass the felicity of Augustus and the virtue of Trajan."

Adrian, the nephew of Trajan, was nominated to the throne, in the last moments of his predecessor, and his title was peaceably acknowledged. Under his reign the empire flourished: he encouraged the arts, reformed the laws, asserted strict military discipline, and visited all his provinces in person. He adopted a policy very different from that of his predecessor, and judging the limits of the empire too extensive, abandoned all the conquests of Trajan, bounding the eastern provinces by the Euphrates. To his talents as an able politician, he joined an excellent taste in the liberal arts. In the last year of his life he adopted, and declared for his immediate successor, Titus Aurelius Antoninus, and substituting Annus Verus, the son of Ælius Verus, in case of the other's death. Adrian died A.D. 138, at the age of 62.

The emperor Adrian suppressed the departments established by Augustus, and divided the whole empire into eleven parts, as follow.

I. Italy, including two provinces, of which the first comprehends all the country from Picenum to Sicily; and the second from Picenum to the Alps, with the two Rhetias.

II. Africa, comprehending the proconsular part of that country; Numidia, and Mauritania.

III. Hispania, including Hispania Tarraconensis; Bœtica, and Lusitania.

IV. Gallia, comprehending Gallia Belgica; Gallia Lugdunensis; Gallia Aquitania, and Gallia Narbonensis.

V. Britanny, comprehending the upper and lower countries of that name.

VI. Illyria, containing seventeen provinces, *viz.* the two Noricas; the Upper and Lower Pannonia, and their appendages; Dalmatia; Mœsia Prima; the Superior and Inferior Dacia; Macedonia; Thessaly; Achaia; the two Epiri, and the island of Crete.

VII. Egypt, including Egypt Proper; Thebais; Libya, and Pentapolis.

VIII. The eastern part of the empire comprehended Palestine; Phœnicia; Cœlo-Syria; Syria; the two Cilicias; Iauria; Mesopotamia; Arabia, and the island of Cyprus.

IX. Thrace comprehended Thrace Proper; the Lower Mœsia; Scythia, and the adjoining countries.

X. Pontus included Pontus Proper; Galatia; Bithynia; the two Cappadocias; Paphlagonia, and Armenia.

XI. The Asiatic division comprehended the proconsular part of Asia; Pamphylia; the countries about the Hellespont; Lydia; Pisidia; Lycæonia; the two Phrygias; Lycia; Caria; and several islands, of which Rhodes was the chief.

*The Age of the Antonines.*—This has by historians been regarded as an era in the Roman empire. Adrian, says the

historian, was resolved to deserve the thanks of posterity, by placing the most exalted merit on the Roman throne. His discerning eye easily discovered a senator about 50 years of age, blameless in all the offices of life; and a youth of about 17, whose riper years opened the fair prospect of every virtue. The elder of these, as we have seen, was declared the son and successor of Adrian, on condition that he himself should immediately adopt the younger. The two Antonines, for so they have been denominated, governed the Roman world 42 years, with the invariable spirit of wisdom and virtue. The former has, on account of his many excellent qualities, been surnamed Pius; the latter, Annus Verus, on his accession, assumed the name of Marcus Aurelius Antoninus. Titus Antoninus Pius has been denominated a second Numa. The same love of justice and peace was the distinguishing characteristic of both princes: but the situation of the latter opened a much wider field for the exercise of those virtues. The wisdom of the former could benefit but a few villages; but Antoninus diffused order and tranquillity over the greatest part of the earth. "His reign," says Gibbon, "is marked by the rare advantage of furnishing very few materials for history; which is, indeed, little more than the register of the crimes, follies, and misfortunes of mankind." In private life, he was an amiable as well as a good man; and he enjoyed with moderation the advantages of his good fortune. He died after a reign of 22 years.

The virtue of Marcus Aurelius Antoninus was of a feverer and more laborious kind. At the age of twelve he embraced, from a conviction of its utility, the rigid system of the Stoics, which taught him to subject his body to his mind, his passions to his reason; to consider virtue as the only good, and vice as the only evil. His "Meditations," composed in the midst of a camp, are not only extant, but still read with delight and advantage; and he even gave lessons of philosophy to the Roman people, as he had before done in several cities of Greece and Asia. War he detested, as the disgrace and calamity of human nature; but when the necessity of a just defence called upon him to take up arms, he readily exposed his person to eight winter campaigns on the frozen banks of the Danube, the severity of which was at last fatal to the weakness of his constitution. Having appeared like a benevolent deity, diffusing around him peace and happiness, he died in Pannonia, in the 19th year of his reign, A.D. 180. His memory was revered by a grateful posterity; and above a century after his death, many persons preserved the image of Marcus Antoninus among those of their household gods.

"If a man," says the historian of these times, "were called on to fix the period in the history of the world, during which the condition of the human race was most happy and prosperous, he would, without hesitation, name that which elapsed from the death of Domitian to the accession of Commodus. The vast extent of the Roman empire was governed by absolute power, under the guidance of virtue and wisdom. The armies were restrained by the firm and gentle hand of five successive emperors, whose characters and authority commanded an involuntary respect. The forms of the civil administration were carefully preserved by Nerva, Trajan, Adrian, and the Antonines, who delighted in the image of liberty, and were pleased with considering themselves as accountable ministers of the laws. Such princes deserved the honour of restoring the republic, had the Romans of their days been capable of enjoying a rational freedom. The labours of these monarchs were overpaid by the immense reward that inseparably waited on their success; by the honest pride of virtue, and by the exquisite delight

delight of beholding the general happiness, of which they were the authors."

Commodus succeeded to the empire on the death of his father. The measures of this reign were as unimportant as the character of the sovereign was contemptible. Commodus had an aversion from every rational and liberal pursuit, and was in many respects very like Nero. To his other crimes, which he had in common with preceding tyrants, may be added, that he entered the lists as a public gladiator, and actually received a stipend for the slaughter of his helpless antagonists. The concubine and some of the chief officers of this emperor prevented their own destruction, by assassinating him in the thirteenth year of his reign, A.D. 193.

Publius Helvius Pertinax was the next emperor, a man of mean birth, but who had risen to esteem by his virtues and military talents. He disappointed the army of a promised reward for his elevation, and, after a reign of 86 days, was murdered in the imperial palace by the same hands which had raised him to the throne. The empire was now put up to auction by the Prætorians, and was purchased by Didius Julianus; but not paying the stipulated price for his elevation, he was deposed and put to death.

Septimius Severus succeeded, whose intention was to erect the fabric of absolute monarchy, and all his institutions operated to that end. He possessed eminent military talents, and it was his boast, that, having received the empire oppressed with foreign and domestic wars, he left it in profound, universal, and honourable peace. He carried with him into Britain his two sons, Caracalla and Geta; and died at York, in the 66th year of his age, after a reign of eighteen years, A.D. 211. He was succeeded by the two sons just named, whose former mutual hatred of each other was increased by their association in the empire; and Caracalla, with brutal inhumanity, caused his brother to be openly murdered in the arms of his mother. His reign, which was of six years' duration, and full of atrocities, was at length terminated by assassination, A.D. 217.

As it would not be consistent with the limits assigned to this article, neither is it at all necessary, to advance step by step through the succeeding reigns; it will be sufficient to transcribe, with very trifling additions, the names of several of the emperors who followed Caracalla.

The disorders in the Roman empire, which began with Commodus, continued nearly a century, till the accession of Diocletian: and this interval was filled by the reigns of Macrinus and Heliogabalus, who were both slain by the soldiers. Alexander Severus was a just prince and a lover of learning; he was successful in his war against Artaxerxes, the new king of Persia, and after that, was slain by some of his soldiers in an expedition into Germany.

Maximin, Maximus and Balbinus, Gordian, and Philip the Arabian, with his son, in whose reign were instituted the secular games, were all raised to the throne by the prætorian bands, and by them killed. Decius, a severe persecutor of the Christians, was drowned while fighting against the barbarians. After this Gallus was slain by the army, at the end of a reign of two years. The life of Valerianus was devoted to the reformation of the manners of his people; but in a war with Sapor, king of Persia, he was captured and fled alive. Gallienus, the son of Valerianus, was lost in luxury and debauchery, and suffered the empire to be torn from him on all sides by barbarians and tyrants. Hence the 30 tyrants, as they are called, though history records the names of 19 only, rose up against him. Among these was Zenobia, wife to Odenatus, prince of Palmyra, a woman of

martial spirit, who spread her conquering arms far over the Eastern world.

After Gallienus were Claudius II., who died of the plague: Aurelian, who carried Zenobia a captive in triumph, and who was murdered by his soldiers: Claudius Tacitus, Probus, and Carus followed in succession. Probus was killed by the soldiers, and Carus was struck dead with lightning.

Diocletian began his reign A.D. 284, and introduced a new system of administration, dividing the empire into four governments, under as many princes. Maximian shared with him the title of Augustus, and Galerius and Constantius were declared Cæsars, or their successors. Each had his separate department or province, all nominally supreme, but in reality under the direction of the superior talents and authority of Diocletian. The two emperors, trusting to a continuance of that order in the empire which their vigour had established, retired from sovereignty, and left the government in the hands of the Cæsars; but Constantius died soon after in Britain, and he was succeeded by his son Constantine, who was proclaimed emperor at York, though Galerius, at first, refused to acknowledge his title. Maximian, however, having once more resumed the purple, bestowed on Constantine his daughter in marriage, and thus he invested him with a double title to the empire. On the death of Maximian and Galerius, Constantine had no other competitor than Maxentius, the son of Maximian, and the contest between them was decided by the sword. Maxentius fell in battle, and Constantine remained sole master of the empire: this was the time in which the cross is said to have appeared in the heavens, in vision, to the emperor, with this inscription, "in hoc signo vinces."

Constantine made a considerable change in the distribution of the provinces which had not suffered much alteration since the arrangement of Adrian. He subjected the whole empire to the dominion of four prefects of the palace; of whom one was placed over Gallia, one over Italia, one over Illyria, and the other over the Eastern provinces. These prefects had under them *proconsuls* in some of the provinces; in others, *magistrates*, called *consuls*, *presidents*, and *correctors*; and a certain number of provinces over which these were placed being united, formed a vicariat. The *prefect of the palace*, under Augustus, was a military officer, in the order of knights. Tiberius increased the importance of the office; but Antoninus was the first who made use of that officer to promulgate, in his name, the laws of the empire. Hence the prefect of the palace became chief judge, who had authority over all other tribunals. In him were united the several offices of constable, chancellor, and superintendent of the finances. Constantine suppressed this office, as held by an individual, and created four prefects of the palace, who had under them *vicars*, whose power extended over a certain number of countries, forming a diocese or department. These officers had the most considerable influence in their departments, and when they quitted the capital, they left their children with the emperor, as pledges of their fidelity.

Under Augustus, and after him, the *proconsuls* were magistrates sent by the senate to correct the existing abuses of the departments: but they had neither the command of troops, nor the administration of the provinces.

The *consul*, called also rector of the province, had only the name and the ensigns of that office, not the power, Augustus governed the departments of the empire, which he had referred to himself, by means of his prætors and consuls.

The *correctors* were officers who were charged to reform the abuses which had crept into the provinces.

The *presidents* were clothed with a much greater power than that possessed by the proconsuls. They were military officers, and had the power of life and death over the army. It was to one of these officers that the provinces of the empire were subjected in each of the great prefectures: thus,

The prefecture of the Gauls, comprehending twenty-nine provinces, was divided into three vicariats, *viz.* Hispania, Gallia, and Britanny.

I. The vicariat of Hispania included seven provinces, of which three were under consuls, and four under presidents.

II. The vicariat of the Gauls included seventeen provinces; six under consuls, and eleven under presidents.

III. The vicariat of Britanny comprised five provinces; two under consuls, and three under presidents.

The prefecture of Italy included likewise twenty-nine provinces, divided into the proconsulship of Africa, and the vicariats of Rome, Italy, Africa, and Illyria. The vicariat of ROME was under consuls, correctors, and presidents; that of ITALY was under consuls and presidents; that of AFRICA was under consuls and presidents; and that of ILLYRIA under one consul, one corrector, and four presidents.

The prefecture of Illyria included eleven provinces; one under the proconsul of Achaia; the vicariat of Macedonia comprehended five provinces, two under consuls, and three under presidents; the vicariat of Dacia was under one consul, and four presidents.

The prefecture of the East included forty-eight provinces; *viz.* three under the proconsul of Asia; fifteen under the count of the East, a companion to the emperor; six under the prefect of Egypt; seven under the vicariat of Asia; eleven under the vicariat of Pontus; and six under the vicariat of Thrace.

We are now arrived to that state of the Roman empire in which it was governed by Christian emperors, and which may be divided into three distinct periods. The *first* will contain the whole time that the Roman world was governed by one emperor only. The *second* commences with the division of the empire, after the death of Theodosius the Great, and goes down to the extinction of the Western empire under Augustulus. The *third* reaches from the fall of the Western empire to the capture of Constantinople, and the destruction of the whole empire.

*Of the Christian Roman Emperors before the Division of the Empire.*—The administration of Constantine was, in the early part of his reign, mild, equitable, and politic. Though strongly attached to the Christian faith, he made no great innovations on the religion of the state. He introduced order and economy into the civil government, and repressed every species of oppression and corruption. But his natural temper was severe and cruel, and the latter part of his reign was deformed by rancour and a most sanguinary rigour. From this unfavourable change of character he lost the affections of his subjects; and from a feeling, probably of reciprocal disgust, he removed the seat of the Roman empire to Byzantium, where a new city was raised; from his name it was called CONSTANTINOPLE; see the article. The court followed the sovereign: the opulent proprietors were attended by their slaves and retainers. Rome was in a few years depopulated, and the new capital swelled almost at once to an enormous magnitude. In an expedition against the Persians, Constantine died at Nicomedia, in the 30th year of his reign, A.D. 337. During this reign the Goths had made several irruptions on the empire, and though repulsed and weakened, they began gradually to encroach on the provinces.

Before we proceed with the monarchs, we may just notice some particulars relating to the state of the Roman empire at this period; for which we shall be chiefly indebted to Mr. Tytler's Elements, already quoted and referred to.

Instead of the ancient republican distinctions, which were founded chiefly on personal merit, a rigid subordination of rank and office now went through all the orders of the state. The magistrates were divided into three classes, distinguished by the unmeaning titles of, 1, the Illustrious; 2, the Respectable; and 3, the Clarissimi. The epithet of *Illustrious* was conferred on, 1, the consuls and patricians; 2, the prætorian prefects of Rome and Constantinople; 3, the masters-general of the cavalry and infantry; and 4, the seven ministers of the palace.

The consuls were created by the sole authority of the emperor; their dignity was inefficient, and their names served only to give the legal date of the year. The dignity of patrician was not hereditary, but was bestowed as a title of honour by the emperor on his favourites. The prætorian prefects were the civil governors of the four departments of the empire. These were the East, Illyria, Italy, and the Gauls: to them was committed the supreme administration of justice, and of the finances.

The *Respectables* were the proconsuls of Asia, Achaia, and Africa; and the military *comites* and *duces*, generals of the imperial armies. The *Clarissimi* included the inferior governors and magistrates of the provinces, responsible to the prefects and their deputies.

The intercourse between the court and the provinces was maintained by the construction of roads, and the institution of regular posts or couriers; under which denomination were ranked the numberless spies of government, whose duty was to convey all kinds of intelligence to the seat of empire. Taxes were levied by the sole authority of the emperor, and subsidies were exacted from all the cities, under the name of free gifts, on various occasions of public concern, as the accession of an emperor, the birth of a prince, &c.

An impolitic distinction was made between the troops stationed in distant provinces, and those in the heart of the empire. The latter, denominated *Palatines*, enjoyed a higher pay, and more particular favour, and having less employment, spent their time in idleness and luxury; while the former, called *Borderers*, who, in truth, had the care of the empire, and were exposed to perpetual hard service, had, with an inferior reward, the mortification of feeling themselves regarded as of a meaner rank than their fellow-soldiers. Constantine also debased the body of the army by the intermixture of Scythians, Goths, and Germans. This mass of heterogeneous parts, which internally laboured with the seeds of dissolution and corruption, was kept together for some time by the vigorous exercise of despotic authority.

Constantine had divided the empire among five princes, three of them his sons, and two nephews; but Constantius, the youngest of the sons, finally freed himself from all his competitors, and ruled the empire alone. During his reign, the Franks, Saxons, Alemanni, and Sarmatians, laid waste all the fine countries on the banks of the Rhine, and the Persians made the most destructive incursions on the provinces of the East. Constantius wasted his time in theological controversies; but before his death, he appointed his cousin Julian to the dignity of Cæsar. He died A.D. 361.

Julian possessed many heroic qualities, and his mind was formed by nature for the sovereignty of a great people; but having been educated under the philosophers at Athens, he had unfortunately conceived a rooted antipathy to the doctrines of Christianity. The reformation of civil abuses

formed the first object of his attention, after which he endeavoured, but without perfection, to undermine and extinguish the Christian religion. To avenge the injuries which the empire had sustained from the Persians, Julian marched into the heart of Asia, and in an engagement, though crowned with victory, he was slain at the age of thirty-one, after a reign of three years.

Jovian, a captain of the guards, was chosen to succeed Julian, who purchased his safe retreat by the ignominious surrender of five provinces. His reign, of seven months only, was mild and equitable, and he restored the Christians to all their privileges as subjects.

Valentinian was chosen emperor by the army on the death of Jovian, who associated with himself in the empire his brother Valens, to whom he gave the dominion of the Eastern provinces, reserving to himself the Western. Valentinian favoured the Christian faith, but did not persecute its adversaries, which was very unlike the conduct of Valens, who, intemperately supporting the Arian doctrine, set whole provinces in a flame, and drew upon the empire a swarm of invaders, in the disguise of friends and allies, but who, in the end, entirely subverted it. These were the Goths, who, migrating from Scandinavia, had, in the second century, settled on the banks of the Palus Mæotis, and thence gradually extended their territory. In the reign of Valens they possessed themselves of Dacia, and were known by the distinct appellation of Ostrogoths and Visigoths, or Eastern and Western Goths. Valentinian died on an expedition against the Alemanni, and was succeeded in the empire of the West by Gratian, his eldest son, a youth of sixteen years of age. Valens was the scourge of his people. The Huns, of Tartar or Siberian origin, now poured down on the provinces both of the East and West. The Goths fled before them. The Visigoths were allowed by Valens to settle in Thrace; the Ostrogoths asked the like liberty, and, being refused, forced their way into the same province. Valens gave them battle at Adrianople; his army was defeated, and he himself slain in the engagement. The Goths, unresisted, ravaged Achaia and Pannonia, and were several times within sight of the walls of Constantinople.

Gratian took Theodosius as his colleague, who, on the early death of his associate, and minority of his son Valentinian II., governed with great ability both the Eastern and Western empire. Theodosius obtained the surname of Great, and having reigned till A.D. 395, he died, leaving two sons, Arcadius and Honorius, assigning to them separate sovereignties. Arcadius was proclaimed emperor of the East, and Honorius emperor of the West. The Eastern empire comprehended Asia Minor, Arabia, Syria, Egypt, Libya, and the several regions on the Danube. The Western empire included Italy, Spain, France, Britain, Germany, Pannonia, and Africa. The Eastern empire subsisted many ages, but the Western soon became the prey of barbarians.

It may be observed, that the reign of Theodosius was signalised by the downfall of Paganism, and the full establishment of the Christian religion in the Roman empire: for, from the time of Numa to that of Gratian, the Romans preserved the regular succession of the several sacerdotal colleges, the pontiffs, augurs, vestals, flamens, &c. whose authority, though weakened in the latter ages, was still protected by the laws. Even the Christian emperors held, like their Pagan predecessors, the office of pontifex maximus. Gratian was the first who refused that ancient dignity as a profanation. In the time of Theodosius, the cause of Christianity and Paganism was solemnly debated in the Roman senate; Christianity was triumphant, and the senate issued a decree for the abolition of Paganism, the destruction of

which in the capital was soon followed by its extinction in the provinces.

*Of the Western Empire.*—In the reigns of Arcadius and Honorius, the sons and successors of Theodosius, the barbarian nations established themselves in the frontier provinces both of the East and West. Theodosius had committed the government to Rufinus and Stilicho during the minority of his sons: of their fatal dissensions the enemies of the empire took every advantage. The Huns overspread Armenia, Cappadocia, and Syria. The Goths, under Alaric, ravaged the borders of Italy, and laid waste Achaia to the Peloponnesus. Arcadius purchased an ignominious peace, by ceding to Alaric the whole of Greece. This prince, now styled king of the Visigoths, prepared to add Italy to his new dominions. He passed the Alps, and was carrying all before him, when he was defeated by Stilicho, then at the head of the armies of Honorius. In the course of a few months, a torrent of Goths breaking down upon Germany, forced the nations whom they dispossessed, *viz.* the Suevi, Alani, and Vandals, to hasten out of Italy. They joined their arms to those of Alaric, who, being thus suddenly reinforced, determined to overwhelm Rome. Stilicho to ward off the threatened danger, promised him, if he would retire, 4000 pounds weight of gold, which engagement Honorius would not ratify. Alaric was not to be trifled with, and he took ample revenge by the sack and plunder of the city. He was anxious to spare the lives of the vanquished, and to preserve the ancient edifice from destruction. This event happened in August 410. Alaric had, as we have seen, ravaged Greece, some time before; and Arcadius, more wise than his brother, was contented to purchase his friendship, by investing him with the matter-generalship of the Eastern Illyricum. He died within a week of the capture of Rome, and was succeeded by Ataulfus, or Adolphus, to whom Honorius gave his sister Placidia in marriage, and, with her, ceded to his brother-in-law a large portion of Spain. With these concessions Adolphus was contented, and, having concluded a peace, he retired into Gaul, A.D. 412. A great part of what remained of Spain had before been occupied by the Vandals. Honorius allowed, soon after, to the Burgundians a just title to their conquests in Gaul. Thus the Western empire was by degrees mouldering from under the dominion of its ancient masters.

In the East, Arcadius died in 408, leaving that empire to his infant son, Theodosius II., whose sister, Pulcheria, swayed the sceptre with prudence and talent during a government of 40 years. Honorius died A.D. 423. The laws of Arcadius and Honorius are, with very few exceptions, remarkable for their wisdom and equity; a singular circumstance, considering the personal character of those princes, and evincing at least that they employed able ministers.

In the reign of Valentinian III., the hordes from the north of Europe again abandoned their own forests and mountains, in quest of new settlements. Under the command of ATTILA (see his article), they defeated the Roman armies, A.D. 452, and threatened total destruction to the empire. He was for a time ably opposed by Ætius, Valentinian's general; the emperor himself being shut up in Rome by the armies of the barbarian, and at length compelled to purchase a peace. On the death of Attila, his dominions were dismembered by his sons, whose dissensions gave a temporary relief to the declining empire. Valentinian was put to death by the guards of his general Ætius, A.D. 455. He was succeeded by Maximus, who had excited the death of Valentinian, and who now married his widow Eudoxia. Within three months of this event he

was deprived of his kingdom by Genferic, king of the Vandals, who was invited by Eudoxia to revenge the murder of her first husband, and deliver her from the power of the tyrant. Maximus fled, but being taken, he was killed, and his body thrown into the Tiber. Genferic carried Eudoxia and her two daughters into Italy, one of whom he married to his son Hunneric, the other he sent back to Constantinople, and married the mother himself.

After Maximus, we have a succession of seven or eight princes, but the events of their several reigns merit no detail. In the reign of Romulus, surnamed Augustulus, the empire of the West came to a final period. Odoacer, prince of the Heruli, subdued Italy, but spared the life of Augustulus, on the condition of his resigning the throne. This occurred A.D. 476. Odoacer retained the possession of Italy during 14 years. In this period, the estates of the Roman senators were divided among his countrymen and soldiers. At the extinction of the Roman empire in the West, Rome and Italy came into the possession of the Ostrogoths. Africa was seized by the Vandals; Pannonia by the Huns; Spain by the Goths, Alans, and Suevo; Gaul by the Franks; and Great Britain by the Saxons. Hence we see the origin of those nations, many of which have proved so illustrious in history.

We cannot close this portion of the history, without some reflections relating to the rise and fall of Rome. The foundations of the greatness of this vast empire have been enumerated as follow. The fidelity of the citizens to each other, and to the state, was confirmed by the habits of education, and the prejudices of religion. Honour, as well as virtue, was the principle of the republic. The ambitious citizens laboured to deserve the solemn glories of a triumph; and the ardour of the Roman youth was kindled into active emulation, as often as they beheld the domestic images of their ancestors. The temperate struggles of the patricians and plebeians had finally established the firm and equal balance of the constitution; which united the popular assemblies with the authority and wisdom of the senate, and the executive powers of a regal magistrate. When the consul displayed the standard of the republic, each citizen bound himself by the obligation of an oath, to draw his sword in the cause of his country, till he had discharged the sacred duty by a military service of ten years. This wise institution continually poured into the field the rising generation of freemen and soldiers; and their numbers were reinforced by the warlike and populous states of Italy, who had yielded to the valour, and embraced the alliance of the Romans. From their institutions of peace and war, Polybius had deduced the spirit and success of a people, incapable of fear, and impatient of repose. The ambitious design of conquest was attempted and achieved, and the perpetual violation of justice was maintained by the political virtues of prudence and courage. The arms of the republic, sometimes vanquished in battle, always victorious in war, advanced with rapid steps to the Euphrates, the Danube, the Rhine, and the ocean; "and the images of gold, or silver, or brass, that might serve to represent the various nations, and their kings, were successively broken by the iron monarchy of Rome."

The rise of a city, which swelled to an empire, may deserve, as a singular prodigy, the reflection of a philosophic mind; but the decline of Rome was from the natural and inevitable effect of immoderate greatness. Prosperity ripened the principles of decay; the causes of destruction multiplied with the extent of conquest; and as soon as time or accident had removed the artificial supports, the stu-

pendous fabric yielded to the pressure of its own weight. "The story of its ruin," says Gibbon, "is simple and obvious; and instead of inquiring why the Roman empire was destroyed, we should rather be surprised that it subsisted so long. The victorious legions, who, in distant wars, acquired the vices of strangers and mercenaries, first oppressed the freedom of the republic, and afterwards violated the majesty of the purple. The emperors, anxious for their personal safety, and the public peace, were reduced to the base expedient of corrupting the discipline, which rendered them alike formidable to their sovereign and to the enemy. The rigour of the military government was relaxed, and finally dissolved, by the partial institutions of Constantine; and the Roman world was overwhelmed by a deluge of barbarians."

The decay of Rome has often been ascribed to the translation of the seat of empire; but the powers of government were divided, rather than removed. The court of Constantinople was erected in the East; while the West was still possessed by a series of emperors, who held their residence in Italy, and claimed an equal inheritance of the legions and provinces. This impaired the strength, and fomented the vices of a double reign; the instruments of an oppressive and arbitrary system were multiplied; and a vain emulation of luxury was introduced and supported between the successors of Theodosius. Extreme distress, which unites the virtue of a free people, embitters the factions of a declining monarchy. The hostile favourites of Arcadius and Honorius betrayed the republic to its common enemies; and the Byzantine court beheld with indifference, or pleasure, the disgrace of Rome, the misfortunes of Italy, and the loss of the West. Under the succeeding reigns, the alliance of the two empires was restored; but the aid of the Oriental Romans was tardy, doubtful, and ineffectual; and the national selfishness of the Greeks and Latins was enlarged by the perpetual difference of language and manners, of interest, and even of religion. Yet the event justified and did credit to the decision of Constantine. During a long period, as we shall see, his impregnable city repelled the victorious arms of barbarians, protected the wealth of Asia, and commanded, both in peace and war, the important straits which connect the Euxine and Mediterranean seas. The foundation, therefore, of Constantinople seems to have more essentially contributed to the preservation of the East, than to the ruin of the West.

On the decline or ruin of the Roman empire, great ignorance and darkness, as to letters and the useful arts of life, began to overshadow the Western world. A barbarous people, untaught in letters, poured themselves into the Western provinces of the Roman empire, and gave the first blow to learning. Academies were ruined, libraries burnt, and the learned compelled to shut up their schools and books too. Nor were those, who in that age were denominated Christian priests, less concerned in the destruction of letters; for as they had been loaded with contempt and injuries, when Paganism prevailed, by the philosophers, they not only armed themselves against those teachers, but endeavoured to forbid their writings, as containing tenets the most dangerous and pernicious to young persons. Both hastened the destruction of letters: nevertheless the age was not destitute of learned men, of whom the following have, among others, been enumerated. Those professing Christianity are Sulpicius Severus, Cyril of Alexandria, Sozomen, Theodoret, Isidore, Sidonius Apollinarius; and among the Pagans, Zosimus and Olympiodorus were of the greatest note.

For the Roman senate, their magistracy, consuls, soldiery, tribes, courts, names, weights, measures, coins, and other matters relating to the antiquities of that people, their policy, religion, law, customs, &c. see the respective articles in this work.

*Of the Eastern Empire.*—The emperors who reigned in the East, previously to the ruin of the Western empire, were Arcadius, Theodosius II., of whom we have spoken, Marcian, who married Pulcheria, the sister of Theodosius, and Leo the Thracian, who reigned 17 years, and died in 474. He was succeeded by his grandson, Leo, the boy who died in his cradle. His father, Zeno, followed, who, in 475, was driven from the throne by Basiliscus, an usurper; but in the following year he recovered it.

The period in which the emperors reigned singly, after the destruction of the Western empire, includes almost a thousand years, extending from 476 to the year 1453; in which year Constantinople was taken by Mohammed II. We shall only notice some of the most celebrated, beginning with Zeno, who, as we have just observed, had been, after a short rebellion, restored to the throne.

Augustulus, at the command of Odoacer, signified his resignation to the still existing assembly of the Western empire; and that assembly, in their last act of obedience to the Roman prince, still affected the spirit of freedom, and the forms of the constitution. An epistle was addressed to Zeno, in which they solemnly disclaim the necessity, or even wish, of continuing any longer the imperial succession of Italy; since, they say, that it is their opinion, the majesty of a sole monarch is sufficient to pervade and protect the East and the West. They, therefore, in their own name, and in the name of the people, consent that the seat of universal empire shall be transferred from Rome to Constantinople: they renounce the right of choosing their master, the only vestige that yet remained of the authority which had given laws to the world; and they add, that the republic might safely be confided in the civil and military virtues of Odoacer, and humbly request that the emperor Zeno would invest him with the title of patrician, and the administration of the diocese of Italy. The deputies of the senate were received at Constantinople with some marks of displeasure and indignation; and when they were admitted to the audience of Zeno, he at first reproached them with the ill usage of some of their emperors, particularly of Anthemius and Nepos. The first, said he, you have murdered, and the second you have expelled; but while he lives, he is your lawful sovereign. Zeno, notwithstanding his harangue, very soon abandoned the cause of his abdicated colleague. His vanity was gratified by the title of sole emperor, and by the statues erected to his honour in the several quarters of Rome. He entertained a friendly correspondence with Odoacer; and he gratefully accepted the imperial ensigns, the sacred ornaments of the throne and palace, which the barbarian monarch was not unwilling to remove from the sight of the people. Zeno died in the year 495, and was said to have been entombed while he was in one of his drunken fits, and before he was dead. He was succeeded by

Anastasius I. who married Adriadne, Zeno's widow, and by her influence was raised to the throne. See ANASTASIUS.

Justin, of whom we have, in the alphabetical order, given a full account, followed Anastasius, and after a reign of nine years he died, leaving his power to JUSTINIAN, see his article, who destroyed the kingdom of the Vandals in Africa by means of his general Belisarius, and that of the Ostrogoths by Narfes. He is particularly famous in having

built the church of St. Sophia, and in having abolished the consulship, long since only a name without power. He died A.D. 565, and was succeeded by Justin II., who established the exarchate of Italy, and who died mad in the year 578. He was followed by Tiberius, one of the captains in Justin's guards, who died in about four years, having first appointed his own great captain Mauritius as a successor. Mauritius, and all his family, were murdered by Phocas, who exercised the same cruelty in his government, as he had in his way to it. He was dethroned by Heraclius in 611, who succeeded him. During the reign of Heraclius, the Persians made very destructive ravages in the empire; this was the period, also, in which Mohammed, prince of the Arabians, founded the Mohammedan religion and power. This new power quickly weakened the empire, by depriving it of almost all its provinces in Asia and Africa. Heraclius died of a dropsy, after a reign of about 30 years. In the course of a few months, Constantine, Heraclionas, and Constant, all ascended the throne; the two first were cut off in a few months. The latter attempted to fix the seat of empire at Rome, but changing his plans, he went to Sicily, where he was killed, leaving three sons to succeed him, who held the government during the remainder of the seventh century. In the eighth, we have Leo Isauricus, or Iconomachus, so called from the persecutions which he instituted against the worshippers of images; also the empress Irene, who restored image worship, and who cruelly put out the eyes of her own son Constantine, for presuming to take the government into his own hands when he was of age.

In the ninth century, the chief among the Eastern emperors were Nicephorus, who dethroned Irene, and who acknowledged Charles the Great, king of France, to be the emperor of the West. Also, Leo VI., surnamed Philosopher, the author of the constitutions that bear his name.

In the tenth century flourished, among many other emperors, Constantine IX., son of Leo VI.; who took possession of the kingdom of Naples, after driving out the Saracens; and Romanus, the son of Constantine IX., who was likewise successful against the Saracens, but he died of debauchery. Nicephorus Phocas, a general of Romanus, married his widow, and assumed the government in prejudice to the sons of his late master. Nicephorus conquered the Saracens, and took Antioch; but he lost Apulia and Calabria, which were taken by Otho the Great, the emperor of Germany. Nicephorus was at length assassinated by his successor, John Zimisces, who associated with himself on the throne Basilus and Constantine, the two sons of Romanus. Zimisces was poisoned by his chamberlain; Basilus and Constantine recovered Apulia and Calabria, and they reigned together fifty years.

In the 12th century, Apulia was lost by Romanus Argyropulus, and in the same period we have Alexius Comnenus, under whom the Crusades took their rise; and John Comnenus, the son of Alexius, whose excellent disposition obtained for him the name of Colojoannes. In his wars with the Turks he was mortally wounded, and was succeeded by his second son, Manuel Comnenus, who has been characterized for his great perfidy. He has been charged with poisoning the provisions which he had engaged to furnish for the army of the emperor Conrad, and at the same time betrayed his designs to the Turks, against whom he was marching. He was succeeded by Alexius II., his son, whose eyes were torn out, and himself deposed and murdered by his cousin Andronicus, who had previously to this assassinated the empress mother. Andronicus ordered a general massacre of all  
the

the Latins at Constantinople, and his cruelties not being confined to them, he was at length torn to pieces by his own people. The territories of his successor, Isaac Angelus Comnenus, were ravaged by the emperor Barbarossa; the emperor himself dethroned, and his eyes put out by his brother Alexius the tyrant, who seized on the reins of government, but was himself soon detested, as well on account of his conduct towards Angelus, as for the debaucheries and cruelties of which he was guilty. The crusaders, wishing to free the people from this tyrant, laid siege to the city, and took it. Alexius was glad to escape with his life, and young Alexius, the son of Isaac, was placed on the throne. This young prince, with the assistance of the Latins, restored his father. His coadjutors, in this act of piety, not receiving the price stipulated for their services, plundered Constantinople, and set it on fire. Upon this the Greeks revolted, and chose Alexius Ducas for their leader, who having caused the young Alexius to be strangled, was himself declared emperor. He was, however, deposed by the Latins, in the year 1204, and this was the commencement of what has been called the

*Latin Empire.*—Baldwin, earl of Flanders, was the first monarch of this dynasty. This prince was killed in a war with the Bulgarians. About the year 1206, David Comnenus, grandson of Andronicus, made himself master of Trebisond, a city of Asiatic Turkey, on the Black sea, which was afterwards considered as the capital of the Greek empire, and continued so till 1462, when it was taken by Mohammed II., and the reigning emperor, with his family, were carried prisoners to Constantinople, where they were mostly put to death.

Baldwin was succeeded, in the Latin empire, by Henry, at the same time that Theodore Lascaris was acknowledged emperor of the Greeks. These two princes made peace. But Henry was afterwards poisoned at Thessalonica, and was succeeded by Peter de Courtenay, a grandson of Lewis le Gros, who was hailed emperor while he was at Auxerre, of which he was the count. He was murdered by Theodore Angelus Comnenus, and was succeeded, in 1220, by Robert, the second son of Peter, the eldest having refused the crown. This Latin emperor made peace with Theodore Lascaris, in order that he might revenge the death of his father, by turning his arms against Theodore Angelus; but Lascaris dying, and being succeeded, in 1222, by John Ducas, Robert found employment in defending himself and his own rights. Under John Ducas the Latin empire was restrained within very narrow limits, and on the death of its emperor, Robert, in 1228, Baldwin II. Robert's brother, was raised to the throne. Baldwin was but eleven years old when he came to the crown. During his reign the Bulgarians laid siege to Constantinople, but were obliged, by the efforts of the Genoese and Venetians, to raise it. Baldwin went into the West to seek succours against his enemies; in the mean time John Ducas died, and was succeeded, in 1255, by Theodore Lascaris II., whose reign was short; and he was succeeded, on the Greek throne, by Michael Paleologus in the year 1260, who, in the following year, attacked and took Constantinople, and thus put an end to the Latin empire, after it had subsisted about fifty-seven years.

*New Empire of the Greeks.*—Michael Paleologus having obtained the sovereignty of both empires, endeavoured by all the means in his power to unite the Greek and Latin churches, but without effect. His whole reign, which lasted almost twenty-four years, was greatly agitated by diligences from within his kingdom, as well as by external enemies. He was succeeded by

Andronicus Paleologus in 1283, who, during a long reign of 46 years, conducted himself extremely ill, suffering himself to be led into every fault by ambitious and designing persons; of these the chief actors were the clergy, to whom he was ever subservient. During his government the Turks made dreadful ravages on the empire. He was at last dethroned by his grandson,

Andronicus II. who had been associated in the government with the late emperor. In this reign also the Turks made great progress, notwithstanding the efforts of Andronicus to oppose them. After a reign of about 17 years he was succeeded by his son,

John Paleologus, who was very young when he came to the throne, and during his minority the government was committed to John Cantacuzenus, who, for some time, performed all the duties connected with his high station on principles of wisdom, united to great moderation. But in 1345 he assumed the imperial title in Thrace, and in 1347 took Constantinople, compelling the lawful prince, John, who had married his daughter, to retire to Salonica. But the exiled emperor, with the aid of the Genoese, obtained his rights, and compelled the usurper to quit the throne and capital; see his article. During the reign of John, the Turks were continually making inroads on the empire, and were often at the very gates of Constantinople. The eldest son of the emperor conspired against his father, but was defeated in his rebellions. During this reign the Genoese made themselves masters of Lesbos, and Amurath I. took the city of Adrianople. John died in 1391, and was succeeded by his second son,

Manuel, who, on the death of his father, was at the court of Bajazet: he made his escape, and came to Constantinople, where he was crowned. He was successful in his wars upon the Turks, took Bajazet prisoner, and afterwards defeated the son, so that the Turks were driven entirely from Constantinople. He was embroiled in a contest with the sultan Amurath: this prince laid siege to Constantinople, on which occasion cannon were, for the first time, employed in the armies of the East. At length the Turks and the Greeks made peace, and in a very short time after Manuel died, and was succeeded by

John II. in the year 1425, who made a most disgraceful peace with Amurath. In a short time he perceived his error, and fought on all sides for assistance. To obtain the requisite aid from the princes in the West, who had refused him succours on account of the schism of the Greeks, he laboured hard to reunite the two churches. While he was losing his time at the council of Ferrara, the Turks were making great progress. After this, Amurath was defeated by the celebrated Huniades, king of Hungary. At length John made peace with Amurath, and ended his days in peace. His brother,

Constantine Dragafes, succeeded him in 1448, and upon the death of sultan Amurath, the empire of the Turks fell to Mohammed II. With this high-minded prince Constantine had the temerity to embroil himself, of which he had ample occasion to repent, for Mohammed laid siege to Constantinople, which he took, after the most extraordinary efforts of courage, as well on the part of the besieged, as on that of the besiegers. This event took place on the 29th of May, 1453. Constantine, not being able to save his capital, refused to survive its hard fate, and was killed in attempting to defend it. Mohammed did every thing in his power to stop the carnage, and afterwards caused the city to be the capital of his empire. Such was the end of the Greek empire, which had succeeded to the Latin empire.

Thus have we traced the progress of the Eastern empire, till it no longer existed; yet for some ages, as we have seen, it not only firmly but proudly lifted up its head, conscious of its vast superiority over the other existing governments of the world, particularly in the reign of Justinian, who overturned the Vandals in Africa, and the Goths in Italy; but in process of time, as has been shewn, it declined in its power, and was dismembered of its parts one after another. As in almost all other cases, the misconduct of the emperors not only hastened the ruin of the empire, but was the primary and leading cause of it. The Bulgarians claimed and obtained a part of the empire; as did the Saracens, who possessed themselves of Syria, Palestine, Egypt, Cilicia, and all the adjacent regions; and after that, overrunning the rest of the Roman world, laid siege to Constantinople. These were the followers of the prophet Mohammed, who, believing the whole world was destined for them as an inheritance, attacked the neighbouring nations with a fury, that, in many cases, was absolutely irresistible. It was in this state of things, when the empire could scarcely defend itself against these Saracens, that Constantinople, as we have seen, was taken by Baldwin, earl of Flanders. It was at this period that another emperor took his station at Trebisonde, that city and the regions round it being torn from the rest of the Roman empire. At last the Turks totally destroyed that empire. They first, in the reign of Heraclius, passing through the Caspian straits, wandered over divers countries in the East, embraced the Mohammedan religion, and were divided into several principalities. But the other tribes becoming extinct, the posterity of Othoman alone took the lead, and ever since the Turkish sovereigns have assumed the name and title of Othomans, or Ottomans. These, having subdued the greatest part of the provinces which had been possessed by the Saracens, swallowed up the rest of the Roman empire. Constantinople, since its capture in 1453, has been the seat of the Turkish emperors; of course it claims no longer our notice in this article.

*Affairs of Rome after the Ruin of the Western Empire.*—We have already observed, that Italy was subdued by the Heruli, whose prince, Odoacer, out of contempt to Rome, fixed his seat at Ravenna. These Heruli were, however, soon driven out of Italy by the Ostrogoths, whose king, Theodoric, erected a new kingdom in Italy, and chose Verona to be the royal seat for him and his posterity. This kingdom lasted from the year 493 to 553; but in 541 Totila succeeded to the throne of the Goths, who in the course of his reign captured the city of Rome, and abandoned it to his soldiers, intending in the end to have razed it to the ground, but was prevented from executing his plan by Belisarius. Teia, the successor of Totila, and the last king of the Ostrogoths, was defeated and slain by Narses, who succeeded Belisarius as general of the armies of Justinian. By this general the kingdom of the Goths in Italy was totally destroyed. Soon after the Lombards erected another kingdom in Italy, and claimed, under their king Alboin, that part of Italy which is still called Lombardy. Their royal seat was Ticinum or Pavia, and their kingdom flourished from 568 to 774, when Charlemagne having taken their capital, carried their last prince, Desiderius, with his family, into France. While the Lombards ruled in Italy, the other parts of that country were in subjection to exarchs or prefects, who were usually sent by the emperor to Constantinople. These, in some measure, resisting the Lombards, defended the remains of the empire there, and fixed their seat at Ravenna. This exarchate lasted 185 years, viz. from 568 to 752, in which year Aistulphus,

king of the Lombards, took Ravenna by force. The kingdom of the Lombards being extinct, all Italy, which had been comprehended under the exarchate and kingdom of the Lombards, fell to the kings of France. Charlemagne was first proclaimed patrician, and soon after emperor, of the Roman people. As the people were prompted to this act by the bishop of Rome, Charles gave a large part of the exarchate and other lands to the bishops of Rome, who became the temporal as well as the spiritual fathers of the people. They contrived at this period a peculiar kind of dominion, which received great strength and advantage from the general ignorance that then prevailed in the West. The bishops of Rome claimed to be the vicars of Christ, and successors to Peter, chief of the apostles, and had therefore a right to prescribe laws to all the Christian world. Formerly, on account of the pre-eminence of the city of Rome, only the bishops of that city claimed a superiority in matters of religion. But when they saw that the bishops of Constantinople assumed to themselves, because the seat of empire had been transferred to that city, the title of oecumenical or universal patriarchs, then the bishops of Rome pretended they had a right to the primacy as successors to the apostle Peter; and at length they were not satisfied with their supremacy in matters of religion, but arrogated to themselves the power of dispossessing princes of their kingdoms. Gregory VII. laid the foundation of this claim, a man, whose ambition, it has been well said, was scarcely to be satisfied by the possession of a world. The other bishops were not all equal in power, but he who dwelt in the metropolis took the lead of the other bishops in that province. At first he was called metropolitan, and in the eighth century he took the name of archbishop. The most eminent of these metropolitans were those of Rome, Constantinople, Antioch, and Alexandria, because these were the principal cities of the Roman empire. And next to these, on account of the supposed sanctity of his city, was the bishop of Jerusalem. The others vigorously defended their privileges against the bishop of Rome, and the controversies that arose thereupon, gave occasion at length to the schism between the Greek and Roman churches, to which we have had occasion to refer.

The see of Rome maintained its authority without much interruption till the 14th century, when it began to totter, on account of the schisms that arose among the Roman pontiffs, which lasted nearly half a century, there being two popes at a time, the one at Rome, the other at Avignon. But this schism being terminated the popes recovered their former strength. It was about this same period that Nicholas Gabrini di Rienzi, (see GABRINI,) without rank, without money, without friends, alliances or military force, led on by ambition, and supported by his eloquence alone, obtained for a short time the sovereignty of Rome; and though he could not, as he proposed, make her the mistress of the world, he, however, protected some, and awed other sovereigns, and was admitted an arbiter of kingdoms.

In the fifteenth century the pontiff's authority was again shaken, as well by disputes between the emperor and the popes, three of whom were deposed by the council of Constantine, two others by the council of Pisa, and one by the council of Basil, as by the intrepidity of a second Gabrini, in the character of Stephen Porcario, of whom, his name having escaped us in the alphabetical order, we shall say a few words. He was of noble birth; his reputation was spotless; his tongue was armed with eloquence; his mind was enlightened with learning; and he aspired to free his country and immortalize his name by the glory of his deeds.

deeds. "The dominion of priests," says Gibbon, "is most odious to a liberal spirit." Petarch was now the oracle of the Italians, and as often as Porcaro revolved the ode, which describes the patriot and hero of Rome, he applied to himself the visions of the prophetic bard. His first trial of the people's feelings was at the funeral of Eugenius IV. In an elaborate speech he called the Romans to liberty and arms. For this act he had, by the existing laws of the state, forfeited his life; but the benevolence of the new pontiff, who viewed his character with pity and esteem, attempted by an honourable office to convert the patriot into a friend. He was again guilty of the same offence, and was a second time pardoned. The humane pontiff now removed him from the scene of temptation to Bologna, with a liberal allowance for his support, and the easy obligation of presenting himself each day before the governor of the city. But he formed a party at Rome, and a new conspiracy was excited. His nephew, a daring youth, assembled a band of volunteers, and on the appointed evening a feast was prepared at his house for the friends of the republic. Their leader, who had escaped from Bologna, appeared among them in a robe of purple and gold: his voice, his countenance, his gestures, bespoke the man who had devoted his life to the glorious cause. In a studied oration, he expatiated on the motives and the means of their enterprise; the name and liberties of Rome; the sloth and pride of their ecclesiastical tyrant; the active or passive consent of their fellow citizens; three hundred soldiers and four hundred exiles, long exercised in arms or in brooding over their wrongs; the licence of revenge to edge their swords, and a million of ducats to reward their victory. "It would be easy," he said, "on the next day, the festival of Epiphany, to seize the pope and the cardinals before the doors, or at the altar, of St. Peter; to lead them in chains under the walls of St. Angelo; to extort, by the threat of instant death, a surrender of the castle; to ascend the vacant Capitol; to ring the alarm-bell, and to restore in a popular assembly the ancient republic of Rome. While he was triumphing in his own mind, he was already betrayed. The senate, with a strong guard, invested the house; the nephew of Porcaro cut his way through the crowd, but the unfortunate Stephen was drawn from a chest, lamenting that his enemies had anticipated by three hours the execution of his design. After such manifest and repeated guilt, the pope, though still inclined rather to pity than punishment, could say nothing in his favour. Porcaro, and nine of his accomplices, were hanged; and amidst the fears and invectives of the papal court, the Romans pitied, and almost applauded, these martyrs of their country. "But," says the eloquent historian of the Decline and Fall of the Roman Empire, "their applause was mute, their pity ineffectual, their liberty for ever extinct; and, if they have since risen in a vacancy of the throne or a scarcity of bread, such accidental tumults may be found in the bosom of the most abject servitude." Of the struggles of the people of Rome we have, therefore, nothing more to record.

But the independence of the nobles, which was fomented by discord, survived the freedom of the commons, which must be founded in union. Rapine and oppression were long maintained by the barons of Rome; their houses were a fortress and a sanctuary: and the criminals whom they protected from the law, repaid the hospitality with the service of their swords and daggers. The private interests of the pontiffs, or their nephews, sometimes involved them in these domestic feuds. Under the reign of Sixtus IV. Rome was distracted by the battles and sieges of the rival houses; after the conflagration of his palace, the prothonotary Colonna was

tortured and beheaded; and Savelli, his captive friend, was murdered on the spot, for refusing to join in the acclamations of the victorious Urfini. But the popes no longer trembled on their throne: they had strength to command, if they had resolution to claim, the obedience of their subjects; and the strangers who observed these partial disorders, admired the easy taxes and wise administration of the ecclesiastical state.

The spiritual thunders of the Vatican depend on the force of opinion; and if that opinion be supplanted by reason or passion, the found may idly waste itself in the air, and the helpless priest will be exposed to the brutal violence of a noble or plebeian adversary. But after their return from Avignon, the keys of St. Peter were guarded by the sword of St. Paul. Rome was commanded by an impregnable citadel; the use of cannon is a powerful engine against popular seditions; a regular force of cavalry and infantry was enlisted under the banners of the pope; his ample revenues supplied the resources of the war; and, from the extent of his domain, he could bring down upon a rebellious city an army of hostile neighbours and loyal subjects. Since the union of the duchies of Ferraro and Urbino, the ecclesiastical power extends from the Mediterranean to the Adriatic, and from the confines of Naples to the banks of the Po; and as early as the sixteenth century, the greater part of that spacious and fruitful country acknowledged the lawful claims and temporary sovereignty of the Roman pontiffs. For the successive changes that have occurred in Italy from that time to the year 1811, we refer our readers to the article ITALY, in the New Cyclopædia; and we shall, probably, by the time we come to the article STATE, *Holy Roman*, be able to give a farther account of the subject, to the general peace, we earnestly hope, of 1815.

In the mean time, we shall lay before our readers an account of Rome as it appeared in the fifteenth century to an accurate and feeling mind, and then conclude the article with some account of the present state of the city.

*View of Rome in the Fifteenth Century.*—In the last days of pope Eugenius IV. two of his attendants, the learned Poggio and a friend, ascended the Capitoline; reposed themselves among the ruins of columns and temples; and from that commanding spot, they viewed the wide and various prospect of desolation. The place and the object gave ample scope for moralizing on the vicissitudes of fortune, which spares neither man nor the proudest of his works, which buries empires and cities in a common grave; and it would naturally be inferred, that in proportion to her former greatness, the fall of Rome was the more awful and deplorable. The description of Poggio, who was one of the first that raised his eyes from the monuments of legendary, to those of classic superstition, is as follows:

1. Besides a bridge, an arch, a sepulchre, and the pyramid of Cælius, he could discern, of the age of the republic, a double row of vaults in the salt-office of the Capitol, which were inscribed with the name and munificence of Catullus.
2. Eleven temples were visible in some degree, from the perfect form of the Pantheon, to the three arches, and a marble column of the temple of Peace, which Vespasian erected after the civil wars of the Jewish triumph.
3. Of the number, which he rashly defines, of seven thermæ or public baths, none were sufficiently entire to represent the use and distribution of the several parts; but those of Diocletian and Antoninus Caracalla still retained the titles of the founders, and astonished the curious spectator, who, in observing their solidity and extent, the variety of marbles, the size and multitude of the columns, compared the labour and expence with the use and importance. Of the baths

of Constantine, of Alexander, of Domitian, or rather of Titus, some vestige might yet be found. 4. The triumphal arches of Titus, Severus, and Constantine, were entire, both the structure and the inscriptions; a falling fragment was honoured with the name of Trajan; and two arches then extant, in the Flaminian way, have been ascribed to the baser memory of Faustina and Gallienus. 5. After the wonder of the Coliseum, Poggius might have overlooked a small amphitheatre of brick, most probably for the use of the Prætorian camp: the theatres of Marcellus and Pompey were occupied in a great measure by public and private buildings; and in the circus Agonalis and Maximus, little more than the situation and the form could be investigated. 6. The columns of Trajan and Antonine were still erect; but the Egyptian obelisks were broken, or buried. A profile of gods and heroes, the workmanship of art, was reduced to one equestrian figure of gilt brass, and to five marble statues, of which the most conspicuous were the two horses of Phidias and Praxiteles. 7. The two mausoleums or sepulchres of Augustus and Adrian could not totally be lost; but the former was only visible as a mound of earth; and the latter, the castle of St. Angelo, had acquired the name and appearance of a modern fortress. With the addition of some separate and nameless columns, such were the remains of the ancient city: for the marks of a more recent structure might be detected in the walls, which formed a circumference of ten miles, included three hundred and seventy-nine turrets, and opened into the country by thirteen gates.

*Of the Government of Rome under the Popes.*—For this part of our article we shall be chiefly indebted to the justly denominated “Classical Tour through Italy,” by the Rev. I. C. Eustace, whose partiality for whatever is papal, may render him, perhaps, somewhat partial as an historian. In speaking of this government, as it existed previously to the ravages of the French at the close of the last century, he says, though despotic above all controul, it is exercised by the pontiff with mildness, and submitted to by the people with respect. The sacred character of the bishop influences both the sovereign and the subject. The government is elective; promotion depends in a great degree upon talents and virtues; and, consequently, there is a stimulus to exertion and a scope for honourable ambition. As for the origin of the temporal sovereignty of the popes, it may be most honourably and firmly established on the consent of the people. After the expulsion of the Goths, when the arms of the Eastern emperors had re-conquered, but were incapable of protecting Italy; when the incursions and menaces of the Lombards kept the city in constant alarm, and pestilence and famine had preyed upon it; the Romans naturally turned their eyes to their bishops, and found in them the support which they had vainly solicited from their sovereigns. The pontiffs had till that period been as eminent for their virtues as for their station, and when forced by public distresses to take a considerable share in the administration of the state, they displayed a prudence equal to their sanctity, and a benevolence as extensive as the possessions of the Roman church. “We see them,” says Mr. Eustace, “in the seventh, eighth, and ninth centuries, protecting Rome on one side against the attacks of the Lombards, and securing it on the other from the rapacity and treachery of the exarchs, repairing its walls, feeding its inhabitants, engaging distant princes in its interests, and finally restoring the majesty of its name in the new empire. Rome, indeed, seems to owe her existence to her pontiffs; and had not the chair of St. Peter replaced the throne of the Cæsars, and the seat of empire become the sanctuary of religion, Rome would probably

have sunk into a heap of uninhabited ruins, and left to posterity nothing more than the *wheeling of a mighty name.*”

From the re-establishment of the Western empire to the tenth century, the popes employed their influence in opposing the growing power of the Saracens, and in protecting the coasts of Italy, and the capital itself, against the predatory incursions of those barbarians. Shortly after commenced their contests with the German Cæsars: but however much the popes may be censured, as ecclesiastics, in those destructive quarrels; as princes and as Romans they may claim indulgence, as they struggled against foreign influence, and finally succeeded in freeing Italy from the yoke of a German, a barbarian, and an absentee ruler. The disputes of the popes with the barons and the Roman people were founded on the just opposition of a firm government, to the arrogance and tyranny of an aristocratic body on the one side, and to the licentiousness of a turbulent populace on the other. But Rome has just cause to deplore and condemn the folly and the perversity of her pastors, when they forsook her venerable walls, and submitted to voluntary exile, alternately the instruments and victims of French intrigue and ambition. Of all the disasters that beset Rome in the long series of her eventful history, this, perhaps, was the most pernicious both in its immediate effects and distant consequences, and to it may be ascribed the degradation of the noblest monuments, the depopulation of the capital and its neighbourhood, and the evils that anarchy and tyranny never fail to bring in their train. These evils continued to operate long after their efficient causes had ceased to exist, and the popes, during many ages after their re-establishment in Rome, had to struggle with the restless and unbridled passions excited by the guilt or the folly of their absentee predecessors. Sixtus Quintus succeeded in breaking the spirit of the barons, and having brought the people to submission, he restored order, peace, and industry, to the Roman states.

From this period Rome rapidly increased in prosperity, riches, and population, and became the seat of the arts and sciences, the centre of political negotiation, and not unfrequently of courtly intrigue. Most of the succeeding popes took an active part in the public transactions of the times, sometimes as mediators, but too frequently as parties concerned, with a view to national interests, or to family aggrandizement. Their conduct, in this respect, though little conformable to the principles of their profession, was advantageous to their territories, as it brought wealth to the inhabitants, and reflected lustre on a city, at the same time the metropolis of the Christian world, and the capital of an extensive and flourishing country.

The reformation produced at the time little or no diminution of the temporal greatness and consideration of the popes: so little indeed, that in the century following that event, Rome seems to have enjoyed a splendour and prosperity not witnessed within her walls since the fall of the empire. Hence it has been observed, “that if Pyrrhus’s ambassador could with propriety call the Roman senate in his time a congress of kings, a similar appellation might with equal veracity be applied to the modern senate of Rome, the college of cardinals, during the seventeenth century. That assembly was, strictly speaking, composed of princes, the sons, nephews, brothers, or uncles of the first sovereigns in Europe; men who not unfrequently, as statesmen and ministers, had held the reins of empire at home, or as ambassadors, represented their royal relatives abroad. They either generally resided or frequently assembled at Rome, not only to discharge their duties about the person of the pontiff,

tiff, but to support the interests of their respective courts; and in order to attain this object the more effectually, they displayed a splendour and a magnificence nearly royal. The officers of their household were often nobles of high rank; their secretaries and chaplains were men of talents and business; a long train of guards, servants, and retainers, attended their persons when they appeared in public, and the blaze of the purple, in itself so dazzling, was heightened by all the adventitious circumstances of birth, power, and opulence. The union of so many illustrious personages, vying with each other in talents and magnificence, gave Rome the appearance of an universal court, where all the sovereigns of Europe were assembled to discuss the general interests of Christendom, and to display their rival glories in peace and security."

From this epoch the character of the pontiffs became more episcopal and pacific, and they have chiefly been occupied with the government of the Catholic church over which they preside, and with the civil administration of their own territories, which, as we have seen, are sufficiently extensive to engross their utmost attention. The arts and sciences have at all times, but particularly in the latter centuries, met with special encouragement from the popes; and Rome, enlivened by their constant presence, embellished by their munificence, and fed by the produce of several extensive, populous, and well-cultivated provinces, had gradually resumed her robes of glory, and began to promise herself once more the return of her former dignity and prosperity. "She had," says Mr. Eutace, "been great even in her fall, and venerable in her disasters. She had ceased to be the mistress of the world in arms, but she still remained the mistress of the world in arts; she was no longer the capital, but she was the metropolis of Europe; not the residence of the first sovereign, but the see of the first pastor. She had not been subjected to slavery as Athens; she had not been reduced to a heap of ruins, as Babylon. She still reigned widowed, but independent; and still claimed and enjoyed the veneration of kings and of nations. Without fleets or armies she reposed in fearless tranquillity: public reverence, more mighty than military power, covered her head with an invisible ægis, guarded her frontiers, and secured her repose. Even the nations which had forsaken her communion, and in days of irritation had defied the thunders of her fulminating pontiffs, now looked towards her with respect, and beheld with affection and reverence the benevolence, the sanctity, and the humility of her pastors. Such was the state of Rome during the eighteenth century; a state happy in the enjoyment of peace, plenty, and increasing improvement, and big with the hopes of future and accumulating prosperity. The French invasion closed the scene. See ITALY.

*Of the Present State of Rome.*—The modern city possesses many features of ancient Rome. The same roads lead to her gates—the same aqueducts pour the same streams into her fountains—the same great churches that received the masters of the world under the emperors, are still open to their descendants—the same venerable walls that inclosed so many temples and palaces in the reign of Aurelian, still exist. Modern Rome lies extended principally on the plain, and is scattered thinly over the hills, bordered by villas, gardens, and vineyards. Its population is supposed to amount to 200,000 souls. The streets are well built and paved, narrower, in general, than those in London, and wider than those in Paris: the houses being low, the streets are light and airy: they are many of them very long and straight, and not unfrequently terminated by an obelisk, a fountain, or a church. The houses are of stone, but plas-

tered or stuccoed, as at Vienna, Berlin, &c. This city contains 46 squares, 5 monumental pillars, 10 obelisks, 13 fountains, 22 mausoleums, 150 palaces, and 346 churches.

Of the squares, the most remarkable is the Piazza Navona, which gradually rose on the ruins of the Circus Agonalis. It is adorned by the handsome church of St. Agnes, and refreshed by three fountains decorated with statues. One of these fountains is an object of great admiration, and is thus described. Four figures, representing four rivers, recline on a craggy rock: on its top stands an Egyptian obelisk; from its hollow sides rushes a perpetual stream. These three fountains are so managed during the heats of August, as to inundate the whole square on Saturdays and Sundays, and afford a very refreshing exhibition to the Roman gentry, who parade along in their carriages, and to the common people, who always collect in crowds to behold the enlivening scene. Modern Rome is ten miles in circumference, but this extent comprehends gardens and uninhabited places, and it is defended by the castle of St. Angelo. In the Rione di Monte is the church of St. Giovanni in Laterano, dedicated to St. John in the seventh century, and raised on the ruins of a palace built by Constantine, in the year 324. Near this church is the baptistery of Constatine, celebrated for its ornaments, its antiquities, paintings, columns, and statues. Before the church is an obelisk, constructed at Thebes, in Upper Egypt, and brought down the Nile to Alexandria, from whence, by order of Constantine, it was conveyed to Rome. The church of St. Stephen, found also in this part of Rome, called the *round*, from its form, is an ancient temple of Faunus; it is supported by sixty pillars of granite or marble of the island of Paros. The church of the holy cross of Jerusalem was built by Constantine, and is celebrated for its relics, its columns, and its paintings. The ruins of a temple, dedicated to Venus and Cupid: the monastery of St. Eusebius, built on the ruins of the baths and palace of Gordianus: Trajan's pillar, one of the most beautiful monuments of ancient Rome: the remains of the baths of Titus, of temples dedicated to Concord, to Peace, to Jupiter Tonans, to Jupiter Stator, with many other churches, palaces, and monuments of antiquity, are to be found in this quarter of Rome.

In the Rione di Trevi is found the church of the Twelve Apostles, first built in the reign of Constantine, and rebuilt by Clement XI. This ward likewise contains a church, dedicated to our Lady of Loretto, adorned with Corinthian pillars and the most beautiful statues; the church of St. Mary in Trivio, built or repaired by Belisarius; the churches of St. Vincent, of Anastasius, and many superb palaces. The Rione di Colonna contains, besides churches, the Piazza di Colonna, of which the buildings are handsome: in this square is a fountain, and a marble column of Antoninus, constructed in the time of Commodus, and all of marble: in this ward is the great hall of Justice; the house of the missionaries, whither all ecclesiastics of Rome retire for ten days before they receive holy orders, with several palaces and monuments of antiquity. The Rione di Campo di Marzo contains the ancient Campus Martius; in this are found several beautiful churches and magnificent palaces; among other buildings is the Clementine college, founded by pope Clement VIII. The Rione di Ponte takes its name from the bridge of St. Angelo; in it are found a college for one hundred students, Hungarians and Germans. The Rione della Regola, near the Tiber, contains the Farnese palace, in which is seen the celebrated colossal statue of Hercules, and many others: this palace was built by Michael Angelo, with the stone taken from Vespasian's amphitheatre;

theatre; the gallery was painted by Hannibal Caracci; and the Monte della Pietà, established in the year 1539, for the purpose of lending money on pledges without interest. The Rione di St. Eustachio contains the beautiful church of St. Charles aux Catinari, in which, among many others, is a beautiful picture representing the death of St. Anne; the church of St. Andre de la Valle, which contains some excellent paintings; the college de Sapienza is, perhaps, the most celebrated in the universe; this magnificent building was begun under Leo X. from the design of Michael Angelo; the palace of Justiniani, adorned with a great number of bas reliefs, and antique statues; many of them found on the spot on which were the baths of Nero, and the palace is now erected: the Theatre d'Argentina, and many other palaces, antiquities, and churches. The Rione della Pigna contains the Piazza della Rotondo, in which is a beautiful fountain of white marble, ornamented with an obelisk and dolphins, which spout out the water. The Roman college is a vast and superb edifice, built in the time of Gregory XIV. for the study of the languages and sciences; here is kept the museum of father Kircher, and the library is well furnished: the church of St. Maria della Sopra Minerva, so called from a temple of Minerva which anciently stood there. The ward of the Rione di Campitelli, or Du Capitoles, contains the Capitolinus mountain, the Palatine, and part of mount Cælius; the church of St. Mary in Campitelli, rebuilt in the year 1656, by the people of Rome. Here are found many beautiful statues and pictures, by the most celebrated masters; the Tarpeian rock, now called Monte Caprino; the remains of the temple of Jupiter Tonans; and the church of St. Peter in Carcere; part of the prison constructed by Ancus Martius; the ruins of a temple of Concord; the church of our Lady of Conso-lation; the church of St. Sebastian, built in the ancient Hippodrome. In this ward is found likewise the Coliseum, a superb building, constructed at the command of Vespasian, by the Jews brought from Jerusalem, and destined for the combats of gladiators and public spectacles. In the Rione di St. Angelo is the church of St. Angelo, which gives name to the ward, was built in the eighth century; near it is the theatre of Marcellus, built by Augustus, and capable of holding 30,000 spectators; the palace of Savelli, and the palace of Mattei, celebrated for the pictures and statues which they contain; and many others. The ward of the Rione di Ripa, on the side of the river, includes the Aventine mountain, and the island of St. Bartholomew, inhabited at the time of the expulsion of the Tarquins, and then called Tiberina and Lycania; the church of St. Bartholomew was founded on the ruins of an ancient temple of Esculapius. This island is joined to the rest of the city by two bridges. The church of St. Nicholas in Carcere is built near the common prison; St. George in Valebro; the arches of Septimius Severus and Janus; St. Mary in Cosmedin, built by the earliest Christians, on the ruins of a temple of Modesty; St. Paul without the walls is a patriarchal church, and, next to St. Peter, one of the largest in Rome, built by Constantine; the immense ruins of the baths of Caracalla, in which it is said 3000 persons might bathe at one time; the grand circus; the tomb of Cestius; the catacombs or vaults dug in the stone or solid earth, and used for depositing of the dead in this ward. The Rione di Transtevere is on the other side of the Tiber, and includes the mountain Janiculus; in the church of St. Peter in Montorio is the celebrated picture of the Transfiguration, by Raphael, by some thought to be the most perfect painting that exists; the baths of Severus; the Naumachium of Augustus; and the temple of Fortune. The Rione di Borgo, or Rione del

Vatican; this, too, is beyond the Tiber, and is joined to the rest of the city by means of the bridge of St. Angelo, anciently Pons Cælius; in it is the castle of St. Angelo, anciently called Moles Adriani, from its founder; it is circular, and exceedingly strong: here the papal crown is kept, and prisoners of state are confined; it communicates with the Vatican by a long covered gallery. The church of St. Peter is the chef-d'œuvre of Italy, the largest and most beautiful church in the world. It was projected by Nicholas V.; Julius II. laid the first stone in the year 1506; but the whole building was not finished till the next century: it is said to cover 20 acres, and to have cost upwards of one million sterling. The original artist was Bramante, but the greater part was from the plan of Michael Angelo, who raised the cupola; Maderni finished it in the year 1621. The pavilion of the great altar of this church, and the four wreathed pillars of Corinthian brass which support it, were formed out of the spoils of the Pantheon. The Pantheon, originally dedicated to the honour of all the gods, is now a Christian temple, and is still the most perfect of the Roman temples that now remain, and notwithstanding the depredations it has sustained from Goths, Vandals, and Popes, is still a beautiful monument of Roman taste.

The pope has three fine palaces, of which the principal is the VATICAN, which see. The library of this palace is the largest and most complete in the world, rich, especially in manuscripts, in all languages, and all ages. In Rome, the lover of the fine arts will, after all the depredations of the French, meet with innumerable paintings by the most celebrated masters in the world, and with the finest works of sculpture. Besides the university, which consists of several noble colleges, there are numerous academies and literary societies.

The relative situation of Rome, with regard to other European capitals, is as follows: it is 380 miles from Vienna, 560 from Paris, 740 from Amsterdam, 810 from London, and 900 from Madrid. It stands within 10 miles of the Tuscan sea. Universal History. Holberg's Introduction. Tytler's Elements of General History. Playfair's Chronology. Gibbon's History of the Rise, &c. Encyclopédie Méthodique. Eustace's Classical Tour, 2d edition.

ROME, *Citizen of*, at first, was only a citizen of Rome: at length, the right of citizenship was given to other cities and people, both in Italy and the provinces. It was thus St. Paul was a Roman citizen, Acts, xvii. 21. 37, 38. xxii. 25, 26, 27. xxiii. 26; the city of Tarsus, in Cilicia, a native of which he was, having the right of Roman citizens. See MUNICIPAL CITIES, and PAUL.

ROME DE L'ISLE, JOHN BAPTIST LOUIS, in *Biography*, was born, in 1736, at Gray, in Franche-Comté. He applied himself, from a very early period, with earnestness to the study of natural history and mineralogy; and by his discoveries and writings he acquired a considerable reputation. In 1766 he published "A Letter to M. Bertrand on Fresh-Water Polypes." He drew up descriptive catalogues of many rich collections of minerals and madrepores, of which the most distinguished was that of Davila, in 3 vols. 8vo. 1767. In 1779 and 1781 he published a work, entitled "L'Action de Feu central banni de la Surface du Globe, et le Soleil rétabli dans ses Droits." In 1783 he published that work by which he is best known, entitled "Chrétiologie ou Description des Formes propres à tous les Corps du Règne minérale," 4 vols. In this elaborate performance, the author gives a description of the forms proper to every substance of the mineral kingdom, in a saline, stony, and metallic combination; with figures of all the known crystals, arranged according to the number and dis-  
position

position of their angles. He asserts, which is generally admitted, that every species in the mineral kingdom always takes a polyhedral form, which is regular, constant, and peculiar to itself. Besides the works already mentioned, he published "Caractères extérieurs des Minéraux," 8vo. 1784; and "Metrologie ou Tables pour servir à l'Intelligence des Poids et des Mesures des Anciens d'après leur Rapport avec les Poids et les Mesures de la France," 8vo. 1789. This philosopher died at Paris, in 1790.

ROMÉ, in *Geography*, a town of Brasil, in the government of Goyas; 85 miles E. of Villa Boa.

ROME, a post-town of America, in the county of Oneida, and state of New York, situated on the Mohawk river; 8 miles W. of Whitestown. This town was taken from Stauban, and incorporated in 1796. N. lat.  $43^{\circ} 12'$ . W. long.  $75^{\circ} 30'$ .

ROME *du Tarn, St.*, a town of France, in the department of the Aveyron, on the Tarn; 4 miles N. of St. Afrique.

ROME *Scot.* }  
ROME *Peny.* } See PETER-PENCE.

ROMELIA, in *Geography*. See ROMANIA.

ROMELSO, a cluster of small islands on the west side of the gulf of Bothnia. N. lat.  $64^{\circ} 55'$ . E. long.  $21^{\circ}$ .

ROMENAY, a town of France, in the department of the Saone and Loire; 15 miles N.N.E. of Macon.

ROMENO, a town of the county of Tyrol; 13 miles S.W. of Bolzano.

ROMERSBERG, a mountain of Bavaria, in the principality of Aichtatt; 5 miles W. of Aichtatt.

ROMERSGEHAG, a town of Germany, in the bishopric of Fulda; 14 miles S. of Fulda.

ROMERSTADT, or ROMAROW, a town of Moravia, in the circle of Olmutz, near which are some iron mines; 20 miles E.N.E. of Olmutz. N. lat.  $49^{\circ} 50'$ . E. long.  $17^{\circ} 9'$ .

ROMESCAMPS, a town of France, in the department of the Oise; 6 miles N.W. of Grand Villiers.

ROMETTA, a town of Sicily, in the valley of Demona; 5 miles N.W. of Messina.

ROMFORD, a market-town and parish in the liberty of Havering-atté-Bower, county of Essex, England, is situated at the distance of 17 miles S.W. from the county town of Chelmsford, and 12 miles E.N.E. from London. This town is supposed by Stukeley to occupy the site of the Roman station Durohitum. The same author conjectures that its present name is a contraction for Romanford; and in this opinion he is supported by Mr. Lethieullier. Lysons, however, derives it from the Saxon words *Rom* and *Ford*, which signify the Broad-Ford, in allusion to an ancient passage through a rivulet which flows past the western extremity of the town. Romford is first mentioned in record in the Red Book of the Exchequer; where it is said that, in 1166, Roger Bigod, duke of Norfolk, held "the wood of Romford by serjeancy, and payment of five shillings a-year." It is next noticed in 1277, at which time the manor formed part of the possessions of Adam de Cretinge. It afterwards passed to Thomas de Brotherton, earl of Norfolk, from whom it descended by marriage to the Mowbrays, dukes of Norfolk; but on the death of John, the fourth duke, without male issue, in 1477, it became vested in James, lord Berkeley. Since that period it has belonged to different families, and is now the property of a gentleman named Newnan.

Romford is governed by a bailiff and wardens, who, though forming no corporation, are empowered by letters patent to hold a weekly court, for the trial of all causes, whether civil or criminal, high treason not excepted. In

ecclesiastical jurisdiction, however, it is subordinate to Hornchurch, except so far as concerns the maintenance of the poor; in which particular it was recognised as a separate parish, in the year 1786. The privilege of holding a weekly market was first granted to the inhabitants by king Henry III.; but at present here are three: one on Monday, for the sale of calves; another on Tuesday, for hogs; and a third on Wednesday, for corn and cattle. There is likewise an annual fair on the 24th of June. The church or chapel of Romford is an ancient structure, and was probably erected about the commencement of the 15th century, when the inhabitants obtained a bull from the pope, authorising them to consecrate a cemetery adjoining the town, for the burial of their dead, who had, previously to that time, been carried to Hornchurch burying-ground. In this chapel were, in Catholic times, a guild and a chantry; the former of which was valued at 4*l.* 10*s.* 2*d.*, and the latter at 13*l.* annual revenue, at the era of the dissolution. The principal monuments here are those of sir George Hervey, knight, lieutenant of the Tower, who died in 1605, and his lady, both of whom are represented kneeling; and of sir Anthony Cook of Gidea-Hall, and his lady, whose effigies are exhibited in similar positions. On the latter tomb are several inscriptions in Latin, said to have been written by the daughters of the deceased, who were the most learned females of the age. Not far from the church is a charity-school for forty boys, and another for twenty girls, which were founded and endowed in 1728; and at a short distance from the western end of the town are barracks for the accommodation of a regiment of cavalry, erected in 1795. According to the population census of 1811, the parish of Romford, including the Town ward, Collier-row ward, Harold's-wood ward, and Noah-hill ward, contains 620 houses, and 3244 inhabitants.

The district called Havering-atté ward, which comprehends the three adjacent parishes of Hornchurch, Romford, and Havering, anciently constituted part of the demesnes of Saxon kings; and even to this day it possesses peculiar privileges, both as prescriptive rights, and by charter, granted by Henry IV., and since confirmed by several of his successors. Near the village of Havering-atté-Bower was formerly a palace, which tradition ascribes to king Edward the Confessor, and which subsequently became the occasional residence of more than one monarch of the Norman line. The situation of this palace is very fine, and commands extensive views over parts of Essex, Hertfordshire, Kent, Middlesex, and Surrey, as well as of the river Thames. The surrounding park, now the property of the crown, but let on lease, exceeds a thousand acres in extent. To the westward of this park, about two miles, lies Hainault-Forest, in which is a very remarkable tree, called Fairlop-oak, which Gilpin informs us, in his "Remarks on Forest Scenery," is traced by tradition "half way up the Christian era." It is generally said to be the largest tree in this kingdom, measuring 36 feet in girth near the base or root, and spreading its branches over a circumference of 300 feet. At Hempstead, in Essex, is a tree of much larger dimensions. Round the Fairlop-oak, on the first Friday in July, is held an annual fair, which appears to have originated from a gentleman, named Day, who commenced the practice of dining with his friends annually under its shade.

About a mile to the eastward of Romford is Gidea-Hall, an ancient seat of the Cook family; and near it stands Hare-Hall, a mansion formerly belonging to John Aruold Wallenger, esq. The house was built under the direction of Mr. Payne, in 1769, and is constructed of Portland

stone; it consists of a centre, with two wings, connected by colonnades. A small villa in this neighbourhood, at Hare-street, is the residence of Humphrey Repton, esq., distinguished for his taste and talents as a landscape-gardener. He is also author of two or three elegant volumes on picturesque scenery, and the principles of taste, as displayed in the embellishment of parks and gentlemen's mansions. His son, John Adey Repton, is also justly celebrated for his intimate knowledge of the principles and history of the ancient architecture of England. Four miles to the eastward is the village of Brentwood, or Burnt-wood, which was anciently a market-town; but this privilege is now lost. Its former importance, however, may be conjectured from the fact of the county assizes having been held here for many years. The remains of the town-hall and prison are still discernible in the main street, which stretches itself along the Harwich road, and abounds with inns and public houses for the accommodation of travellers. Here is a grammar-school, founded in 1537 by sir Anthony Brown. Camden supposed the Roman station of Cæsaromagus to have been situated at or near Brentwood; but this opinion is not supported by any facts, or even probability.

Five miles westward from Romford is Wanstead-House, the seat of William Pole Tilney Long Wellesey, esq., M.P., who acquired it by marriage with Miss Tilney Long, eldest daughter and co-heiress of the late sir James Tilney Long. It is a very spacious and magnificent building, measuring 260 feet in front, and nearly 80 feet in depth. In the centre of the principal front is a grand portico, supported on six Corinthian columns, and having on each side a flight of steps, and in the tympanum the arms of the Tilney family, finely sculptured. The house is divided into two stories, the uppermost of which contains the ball-room and principal apartments. Several of the rooms contain a collection of fine paintings by eminent artists. The gardens and pleasure-grounds were laid out by Richard Child, previously to the erection of the house; but latterly great alterations and improvements have been made in the former, under the direction of Mr. Repton, who has very properly revived part of an old and almost exploded fashion, in decorating the lawn immediately adjoining the house with flowers, beautiful shrubs, &c. to regale and "delight the senses of seeing and smelling." At the splendid mansion of Longleat, Wiltshire, this has been adopted on a large scale, and with singular beauty. (See WARMINSTER.) Opposite the back front is an easy ascent, through an agreeable vista, to the river Roding, which is formed into canals, and has near it a curious grotto, constructed by the second earl Tilney, at an expence of 2000*l.*, exclusive of its costly materials. Within the park, on its southern side, a tessellated Roman pavement was discovered in the year 1735. It was about 20 feet long, and was conjectured by Mr. Lethieullier to have been the pavement of a banquetting-room. In the centre was the figure of a man, and around him a great variety of ornaments. The History and Antiquities of the County of Essex, by Philip Morant, M.A., 2 vols. folio, Lond. 1767. Lysons's Environs of London, 4to. 1796. Beauties of England and Wales, vol. v. by John Britton and E. W. Brayley, 8vo. Lond. 1803.

ROMHILD, a town of Germany, in the county of Henneberg; eight miles S.E. of Meinungen. N. lat. 50° 26'. E. long. 10° 42'.

ROMI, a town of Asiatic Turkey, in the province of Diarbekir; 45 miles S. of Kerkisch.

ROMIEU, M. of Montpellier, in *Biography*, published in 1743 and 1751, what he called "A New Discovery of

the grave Harmonics," meaning the third sound, resulting from the coincident vibrations of two acute simultaneous sounds; a phenomenon which Tartini had discovered in 1714, and upon which he afterwards built his system, or "Trattato di Musica," published in 1754.

This discovery of Tartini excited the envy, not only of Romieu, but of d'Alembert, Serre of Geneva, the abbé Rouffier, Laborde, &c. The first attempt was to rob him of the honour of the *discovery*, and then to depreciate his explanations, and the *consequences* which he derived from the phenomenon. But it appears to us, on the most careful and minute enquiry, that they have egregiously failed in both. With respect to his *discovery*, Tartini himself, and his zealous disciple count Taxis, of Venice, have clearly authenticated his title to it. (Risposta di Tartini alla critica del di lui Tratt. di Mus. Ven. 1767—et Risposta di un Anonimo al Sig. Rousseau circa al suo sentimento in proposito d'alcune propos. del Giuf. Tartini, Ven. 1769.)

And the long extracts given from Romieu's laboured memoir on the subject of his discovery of the *terzo suono*, by Laborde, in his "Essai sur la Musique," have so much puzzled the cause, that he may be truly said to "explain the thing till all men doubt it," &c.

Tartini himself, by his notation of each *third sound*, produced, as is supposed, by the coincident vibrations of any two simultaneous intervals, is clear and evident. Stillingfleet's commentary of Tartini's "Trattato di Musica," and Rousseau's analysis of his system, do justice to his ingenuity and profound harmonical knowledge, without concealing his defects.

Perhaps we have no right to imagine ourselves unprejudiced in this discussion; having been so long accustomed to regard Tartini as a great practical musician, and an exquisite composer, we may have been insensibly inclined to respect his theory, and, indeed, whatever he has produced; for what more can science do for any musician in the practice of his art, than it has done for Tartini? Has it taught his mathematical opponents, of the old French school, to compose elegant, graceful, spirited, or fanciful music? or even informed them in what good music consists? See TARTINI and TERZO SUONO.

ROMIEU, *La*, in *Geography*, a town of France, in the department of the Gers; five miles E. of Condom.

ROMILLY, a town of France, in the department of the Aube, and chief place of a canton, in the district of Nogent sur Seine; nine miles E.N.E. of it. The place contains 2175, and the canton 6888 inhabitants, on a territory of 267½ kilometres, in 15 communes.

ROMISHORN, a town of Switzerland, in the canton of Zurich; nine miles E.S.E. of Constance.

ROMKALA, a town of Asiatic Turkey, in the government of Marasch, on the right bank of the Euphrates, where the river Simeren joins it. This town has a castle, much ruined, which was the work of the Greek emperors, and which is situated at the N. end of a chain of mountains over the river. It stands on a path, separated from the mountains, to the south, by a deep fosse cut in the rock, and originally intended, as it is said, to be made so deep that it might be supplied with water by the river Simeren, and thus the place be insulated. On the W. side is the ascent, having four terraces cut in the rock, and situated above one another, each having a gate-way, and connected by steps. In the castle are two churches; 50 miles N. of Aleppo. N. lat. 36° 35'. E. long. 37° 45'.

ROMKERA, a town of Hindoostan, in Vishapour; 28 miles N.E. of Poonah.

ROMKINT,

ROMKINT, a town of Asia, in the country of Karasm; 230 miles N.W. of Samarcand.

ROMMEN, a town of Prussia, in the palatinate of Culm; eight miles S.E. of Lautenburg.

ROMMENDAL, a town of Norway; 24 miles N. of Berga.

ROMNA, a town of Russia, in the government of Tchernigov; 88 miles N.E. of Tchernigov. N. lat. 50° 36'. E. long. 33° 24'.

ROMNEY, GEORGE, in *Biography*, was born at Dalton, in Lancashire, in December 1734. His father was a native of the same place, where, upon a small patrimonial estate, he followed the threefold occupation of merchant, builder, and farmer; but as his family was large, the joint profits of his triple concerns barely afforded the means for its maintenance. At the age of 12, George was taken from the village school, where he had imbibed the rudiments of learning, and engaged by his father to superintend the workmen. He employed his leisure hours in carving, and being fond of music, made a violin for himself, which he preserved till his death.

He was first tempted to draw, from seeing some ordinary prints in a periodical magazine, which he imitated with considerable success; and his first attempt at drawing a portrait was from memory, when endeavouring to describe the features of a stranger whom he had seen at church. When he was about 15, his mind was led astray from the occupations in which his father had engaged him, by the society and conversation of a peculiar, but ingenious man, named Wilkinon, who resided at Dalton. He was afterwards placed under the care of a Mr. Wright, a cabinet-maker at Lancaster; but he, soon perceiving the turn of Romney's mind for drawing, advised his father to leave him at liberty to indulge his propensity, and become a painter. At the same time he recommended an artist of the name of Steele, as a preceptor for the youth; and with him he continued to study and practise for a short time only, in which, however, he acquired, to a certain extent, the knowledge and use of the materials of the art.

When he left Steele, and had begun to practise portrait painting as a means of subsistence, he became anxious to visit, and tempt his fate in the metropolis. He laboured therefore very hard, painting portraits at low prices, and occasionally producing pictures of historical subjects, which he disposed of by way of raffle at Lancaster. By these means he acquired a sum of nearly a hundred guineas; of which taking thirty pounds to pay his travelling expences, and leaving the remainder with his wife, he set out to put his long intended project into execution, in the year 1762.

He first resided in the city, where he painted portraits at five guineas a head, and acquired considerable practice through the friendly assistance of Mr. Braithwaite, then of the post-office. In 1764 he visited France, in company with Mr. Green, of Gray's Inn. There he was introduced to Vernet, and, by his friendly assistance, obtained admittance to the gallery of the duke of Orleans, the Luxembourg, and other repositories of art. On his return, he took up a residence in Gray's Inn, to be near his travelling companion; and, by a picture of judge Yates, obtained favour among gentlemen of the robe, and afterwards produced many excellent pictures of persons eminent in that profession. In 1765 he obtained a prize from the Society for the Encouragement of Arts and Sciences, for an historical picture, the subject of which was the death of king Edmund. In 1768 he quitted Gray's Inn, and went to live in Great Newport-street, where he continued to advance in reputa-

tion and practice; exhibiting with the incorporated society of artists in Pall Mall, and in Spring Gardens.

Though thus rapidly gaining public respect as an artist, Romney was himself so conscious of his want of style, and the necessity of cultivating his taste by seeing the great models of antiquity, that he nobly resolved upon relinquishing, for a time, the pecuniary advantages his talents acquired him, (which now amounted to 1200*l.* a-year,) and visit Italy, where alone he could, at that time, attain the object of his desire. He accordingly arranged a plan of travel with Mr. Ozias Humphrey, a miniature painter of celebrity, and on the 20th March 1773, they set forward on their journey, through France, to Rome. There, and at other places, where the best works of art were to be found, he remained two years; leading a life recluse and studious, and making some few copies.

On his return, in July 1775, he took the house in Cavendish-square, where he resided till he retired, in 1798, from public practice, to live at Hampstead, in a house he had built; and where he hoped to recruit a weakened constitution by tranquil enjoyment, and the beneficial effects of purer air. During the preceding 20 years, Romney had enjoyed uninterrupted success in the practice of his profession, to which he was so ardently attached, that his whole delight was in it. His talents, in return, were highly esteemed, and encouraged by an immense influx of employment. He, in measure, divided the attention of the town with Reynolds, and indeed by numbers was preferred before him; but he wanted the suavity of mind and manners which his accomplished rival enjoyed. Timid and reserved, and, at the same time, ardent and enterprising, his imagination was tremblingly alive to those irritating circumstances, by which vulgarity and ignorance constantly wound the mind of the portrait painter, and subject him to mortification and disgust. The slightest appearance of coldness in a friend, or of hostility in a critic, was often sufficient to obstruct the exertions of his faculties. This timidity and reserve were the reasons that, amidst the immense crowd of persons to whom, of course, by his professional practice, he was known, there were few with whom he lived in friendly intercourse. His mind dwelt constantly on the art he delighted and excelled in, and among those only who sympathized with his peculiarities, was he happy to associate.

Romney was subject to occasional depression of spirits, which the kind attentions of his friend Hayley, and the invigorating air of the Suffex Downs, among which that friend resided, and where our painter usually spent his summer months, often partially removed. On the approach of age, he was less able to cope effectually with attacks of that nature, and they gained strength upon him to an alarming degree. In 1797 he felt a slight paralytic stroke, which affected his eye and his hand, and prevented him from continuing his professional labours. He then retired, as we have said, to Hampstead, but finding his health still decline, he, in 1799, revisited his native country; and at Kendal received from a wife, whom, though deserted for so long a space of time, he had supported, and protected from poverty, a kind and affectionate attention till his death, (which occurred in Nov. 1802,) having unhappily survived the loss of that faculty which is the distinguishing glory of man, and relapsed to the helpless state of infancy.

Of Romney, as an artist, it is by no means easy to appreciate the just character. That he possessed genius and talents in an eminent degree, no one can deny. The learned editor of Pilkington's Dictionary has said, "that he was made for the times, and the times for him." It had perhaps been more just to have observed, that Romney was made for bet-

ter times than those in which he lived. His perception of art was far purer than most of his contemporaries, at least in this country, were capable of enjoying; and it must be remembered, that no one ever set forth in the career of an artist under greater disadvantages than he did. The taste he imbibed for simplicity and grandeur, on seeing, at an advanced period of his life, the works of the ancient artists, prove what might have been fairly expected of him, had he happily been born under more favourable circumstances; and early initiated, under good instructors, in the mysteries of the art he cultivated with so much success without those aids. Till the time he was twenty-two he had seen no better painting than the sign of a public house, in the place where he was born; but to his active, enterprising spirit, all nature was a school; and at an age when others are employed in laying by stores of ideas from books, and thence forming regulations to guide their future progress in art, he was industriously observing and reflecting upon the grand scenery around him, and the various characters of the objects among which he lived. Thus, the little learning he had imbibed from the few literary works he had seen was called into immediate action, and his progress in real knowledge became equal to what is usually obtained in the ordinary way, with greater assistance from books and masters.

The pursuit of painting, however, requires a knowledge of certain rules in the arrangement of lines; of the beauty and power of contrast in light and shade, and in form and colour; as well as of the speediest and most efficient modes of execution. This science, being the result of repeated observations upon the principles by which Nature produces her most agreeable and sublime effects, is most readily obtained, by a careful inspection of good works of art wherein it is exemplified. Such advantage was not Romney's. He had to separate for himself the partial, from the general effects of nature; and the inequality with which he, in this point, met the rivalry of more fortunate artists, is too evident in most of his productions. Frequently, his chiaro-scuro is ill conducted, and his harmony of forms and colours imperfect; even in pictures produced when enjoying the height of his intellectual power, and at the happiest period of his executive skill: at the same time they exhibit great fertility of invention, with sweetness and delicacy of sentiment.

He was happily endowed with an inquisitive mind, that delighted in science, and pursued it warmly, with the best means he had: and he possessed a versatility of genius, which is exemplified by the variety of subjects he chose for representation. Both the comic and serious impressions of the mind had charms for him. Early in life he painted two pictures from *Tristram Shandy*; one, of the arrival of Dr. Slop at Shandy-hall, after the unlucky catastrophe he met with on the road; which afforded scope for sentimental comic humour; the other from the affecting story of the death of *Le Fevre*: both of them were highly approved for truth and propriety of feeling and expression, though differing so widely in their effects upon the mind. His journey to Italy expanded his view of art: new scenes, and new sources of information, were presented to him, of which he did not neglect to avail himself. The works of fancy he produced after his return home exemplify the use he made of the two years he spent among the unrivalled productions of art he there met with. The purity and perfection of ancient sculpture appear to have made the deepest impression upon his mind: and he afterwards assiduously cherished the taste he then imbibed, by procuring a collection of casts from the best models of ancient statues, groups, basso-relievos, &c. which he would fit by

the hour to contemplate; examining their appearances under all changes of sun-shine, and common day-light; and with lamps, prepared on purpose, he would try their effects in various modes of illumination, with rapturous delight. Hence, grandeur and simplicity became the principal objects of his ambition; he perceived these qualities distinctly, and employed them judiciously; even whilst imitating nature in his most usual occupation,—portrait painting. To present his figure, or tell his story, with simple undisturbed effect, rejecting all unnecessary minutiae, was the point he aimed at and obtained.

On his return from the continent, his zeal for historical painting revived, or rather became strengthened. In several epistles to Mr. Hayley, he laments his confinement to portraits: in one he says, "this cursed portrait painting, how I am shackled with it! I am determined to live frugally, and cut it short as I can." In another, he mentions his "wish to be retired, in order to compose with more effect and propriety." And whenever he returned to London from Eastham, the hospitable retreat of his admiring correspondent and friend, whose playfulness of fancy was a constant and useful stimulus to Romney's dejected and desponding mind, he felt it a weight of drudgery again to fall into the trammels of portraiture: yet from the enjoyment he by nature found in the practice of his profession, a short time inured him afresh to it, and still he felt pleasure in tracing the features of each new face that presented itself; till again his exalted frame required the exhilaration of retirement, and the refreshment afforded by pure uncontaminated air, free from the gross vapours that hover in the region of a great and populous city. It is not a little surprising, that amidst his continual labours in that branch of the art he more immediately professed, he should have found time to produce so great a number of fancy pictures as he left behind him. He also frequently spent his evenings in making large cartoons in charcoal, of subjects which suited his fancy;—generally of a sublime cast. Amongst these, was one of the dream of *Atossa*, from the Persian of *Æschylus*, which was conducted with the taste and feeling of the ancient Greek artists.

He was in general fortunate in the choice of his historical subjects; and certainly, in this respect, had far the advantage of his great rival, *Mr. Joshua Reynolds*: and no less so in the power of expression, which he scarcely ever failed to obtain: whilst the latter, in his historical pictures, has rarely been so happy. *Reynolds* gave beauty and grace to his figures: *Romney* imparted soul. The former delights the eye with the harmony and richness of colour, and beauty of effect; the latter thrills and gratifies the heart with truth and force of expression, in action and countenance; wrought with more simplicity, but with less art. His picture of *Ophelia* seated upon a branch of a tree, the breaking of which threatens her destruction in the stream below, whilst the melancholy distraction visible in her lovely face accounts for her apparent insensibility to danger, is a sufficient proof of this assertion. His composition also of "*Titania* and her *Indian Votaries*," in the possession of *Mr. Beckford*; "*Titania, Puck, and the Changeling*," at *Mr. John Leicester's*, and others of his works of the like playful and interesting kind, might be brought forward to support it. In portraiture, however, the justly exalted president of the Royal Academy stood alone, and *Romney* was not able to cope with him. In the composition of his figures, our artist exhibited the taste he had acquired by the study of the antique; and he admirably varied the characters of his heads. The arrangement of drapery which he adopted, partook largely of the same style; and being well understood, was painted with great dexterity;

## ROMNEY.

dexterity; though it must be confessed, that in form, it was not unfrequently better adapted to sculpture than to painting. His style of colouring was simple and broad. In that of his flesh he was very successful; exhibiting a great variety of complexion, with much warmth and richness. It was not always, however, that his pictures were complete in the general tone; but crude discordant colours were sometimes introduced in the back-grounds, which not being blended or broken into unison with the hue of the principal figures, interrupted the harmony of the whole. The executive part of his works was free, learned, and precise, without being trifling or minute, possessing great simplicity, and exhibiting a purity of feeling consonant with the style of his compositions. He aimed at the best of all principles in the imitation of nature, *viz.* to generalize its effects; he even carried it so far as to subject himself to the charge of negligence in the completion of his forms: but the truth of his imitation is sufficiently perfect to satisfy the minds of those who regard nature systematically, and not individually, or too minutely. In a word, every lover of art who knows how to appreciate truly what is most valuable in painting, will hold the name of Romney in increasing estimation, the more frequently and impartially he examines his productions.

ROMNEY, *Nerv.* in *Geography*, one of the Cinque-ports, locally situated, partly within the liberty of Romney Marsh, partly within the level of Walland Marsh, and partly in the lower half hundred of St. Martin's Pountney, lathe of Shepway, county of Kent, England. It is distant 37 miles S.E. from Maidstone, and 71 miles S.E. by E. from London. This town is described as having risen from the ruins of Old Romney, at least a century previous to the Norman conquest. Subsequent to that event, it was bestowed by king William I. on Odo, bishop of Baieux, and earl of Kent, and was declared to be privileged as one of the Cinque-ports, having Old Romney, Lydd, Denge-marsh, and Oswardestone, and part of Promhill parish, annexed to it as members, which were to fend out jointly five vessels of war, with twenty-one men and one boy to each of them. At this period, and for many years afterwards, New Romney was a very flourishing place. It was divided into twelve wards, and contained within its liberty five parish churches, a priory, and an hospital for the sick. In the reign of Edward I. however, a great part of it was destroyed by a dreadful tempest and convulsion of nature, which likewise choked up its haven, and thereby prevented its revival as a commercial and shipping town. When Henry VIII. ascended the throne, the sea had retired from it nearly two miles, and all its churches were demolished, except that of St. Nicholas, which is still standing. Henry therefore united the whole liberty into one parish, as it continues at the present day.

In very early times the Cinque-ports were enfranchised with various privileges and customs, though of what antiquity they are, or when so enfranchised, has not been determined with any certainty; they are held therefore to enjoy their privileges by prescription, though these were confirmed by Magna Charta, and since by a charter of king Edward I. New Romney, as one of these ports, is consequently a corporation by prescription; but in Edward III.'s time it was incorporated by charter, first by the style of "barons of the town and port of New Romney," and afterwards by that of "jurats and commonalties of the town and port of New Romney." Queen Elizabeth again incorporated this town, and under her charter the corporation now consists of a mayor, twelve jurats, a chamberlain, recorder, town-clerk, and twenty-six common council-men. The mayor, who is coroner by virtue of his

office, is chosen on Lady-day, yearly; and together with the jurats, who are the exclusive justices within the liberty, hold a court of general sessions of the peace and gaol delivery, and also a court of record. Romney returns two members to parliament, who are usually styled barons, and are elected by the mayor, jurats, and freemen. The first return mentioned on record, is in the forty-second year of Edward III. soon after its separate incorporation.

The town of Romney stands on elevated ground in the centre of a marshy country. It consists principally of one broad well-paved street, intersected by a second, in which the hall or brotherhood house is situated, where the mayors, jurats, and commons of the Cinque-ports, and of the two ancient towns of Rye and Winchelsea, usually keep their court, called the brotherhood; but as it is too small for the purpose, the court called the Guesling, or Gessing, is held in the church. The market-house stands in the main street, and is a modern structure. The day on which the market is held is Saturday, weekly; besides which there is an annual fair on the 22d of August. The church of St. Nicholas is an ancient structure, and consists of three aisles and three chancels, with a square tower at its western extremity. The columns separating the aisles are massive, and support circular arches with zigzag and billeted mouldings. The west door-way under the tower is likewise formed by a circular arch, similarly ornamented. Within this edifice is a great variety of monumental erections, chiefly in memory of persons who have been mayors and jurats of the town. Anciently the church of New Romney belonged to the abbot and convent of Pontinnac, in France, who had a cell or priory here, which was suppressed by king Henry V. Here was also an hospital for lepers, founded and endowed by Adam de Cherryng in the time of king Henry II. There was likewise a house called St. John's house in this town previous to the reign of Edward IV. The only charitable institution now in the parish is an hospital and school-house for the residence of a school-master and four poor persons. According to the population census of 1811, New Romney parish contained 159 houses, and 841 inhabitants.

Old Romney is situated two miles to the westward of New Romney, of which it is a member. This place is said to have been anciently of much importance, and to have constituted one of the original Cinque-ports. Here, in the times of the Romans and of the Saxons, was a commodious haven for shipping, but the sea deserting it occasioned the decay of the town. Somer conjectures, that the Portus Lemanis of Antoninus was situated either at Old or at New Romney; but this opinion is contradicted by later antiquaries, who fix that station near Stutfal castle, at the base of Limne hill. Old Romney now consists only of about twenty houses, with a church, which is an ancient building in the massive circular style. In the north chancel is a very old tomb, with a vault underneath, but there is no inscription to identify its possessor. The font is rudely sculptured, and is supported on four stone pillars.

Romney Marsh is an extensive level of the richest pasture land in England, situated between the upland hills and the sea-shore. This district measures about ten miles in length and five in breadth. It comprehends four divisions, all under different jurisdictions and constitutions, *viz.* Romney Marsh, strictly so called; Walland Marsh; Denge-marsh, with Southbrooks; and Guildford Marsh, part of which is within Suffex. Vast flocks of sheep and herds of black cattle are pastured here. The bullocks of this Marsh are reckoned the largest in England, and the sheep equal to those of Leicestershire and Lincolnshire. So careful were

were our ancient monarchs of this fertile district, that they granted to the inhabitants various important privileges. Edward IV. incorporated the towns of Lydd and Romney, with nineteen parishes, by the title of the bailiff, twenty-four jurats, and the commonalty of Romney Marsh; but the inhabitants exercised many privileges for several centuries anterior to that era. Under the above charter the bailiff, jurats, and commonalty, are empowered to hold a court every three weeks, and to decide on all pleas of action real and personal, civil and criminal. They are likewise empowered to choose four justices of the peace of their own, yearly, besides the bailiff, who possesses similar authority *ex officio*. They have nothing, however, to do with the superintendence or management of the embankments and drainage, which by ancient custom is vested in the lords of twenty-three neighbouring manors, who appoint a bailiff as chief supervisor of the works, who is commonly, though not always, the same person with the bailiff under king Edward's charter. The courts are held in a new hall, in Dimchurch; and at a general one holden on Whit-Thurs-day, all fees and levies, which on an average of years amount to two shillings annually, are paid. Romney Marsh is protected from encroachments of the sea by a wall of great strength, called Dimchurch wall, which extends somewhat more than three miles in length. This wall forms the only highway for carriages along its whole extent, on the road between Hithe and Romney. It measures from twelve to twenty feet in height above the level of the Marsh; and from fifteen to thirty feet in breadth at its summit. "The drainage," says Marshall, in his *Rural Economy of the Southern Counties*, "is effected by arched sluices passing under the bank; each having two pair of flood-gates, one on the outside, the other on the inside, to provide against accidents to the outer pair. These gates permit the interior waters to pass off when the tide is low; and prevent those of the sea from entering at high tide." The History and Topographical Survey of the County of Kent, by Edward Hasted, esq. F.R.S. and S.A. 8vo. edit. Canterbury, vol. viii. A New Topographical, Historical, and Commercial Survey of the Cities, &c. of Kent, by Charles Seymour, 8vo. Canterbury, 1776. *Beauties of England and Wales*, vol. viii. by E. W. Brayley, 1807.

ROMNEY, a post-town of America, the capital of Hampshire county, in Virginia, situated on the W. bank of the S.W. branch of the river Patowmac; 50 miles W. by N. from Winchester. It contains about 30 houses, a brick court-house, and a stone gaol.

ROMONT, a town of Switzerland, in the canton of Friburg, and capital of an extensive bailiwick, which was formerly a county; nine miles N.W. of Friburg.

ROMOPOCK, a town, or rather village, of Bergen county, in New Jersey, on a river of the same name, 15 or 20 miles N. of Patterson.

ROMORANTIN, a town of France, and principal place of a district, in the department of the Loire and Cher; seven miles S.S.E. of Blois. The town contains 5730, and the canton 10,276 inhabitants, on a territory of 330 kilometres, in 10 communes. Its manufactures consist of fine cloths and serges. N. lat. 47° 22'. E. long. 1° 49'.

ROMORSWALDE, a town of Prussia, in the province of Ermeland; five miles N.N.W. of Heilsberg.

ROMPEE, or ROMPU, in *Heraldry*, is applied to ordinaries that are represented as broken; and to chevrons whose upper points are cut off. He beareth a chevron rompee, between three mullets, argent, by the name of Sault.

ROMPION, or RAMPION, in *Botany*. See CAMPANULA *Rapunculus*.

ROMPNEY, in *Geography*. See REMNEY.

ROMPONESCO, a town of Italy, on the Po; 20 miles S. of Mantua.

ROMRA, a town on the W. coast of the island of Lombeck. S. lat. 8° 15'. E. long. 115° 54'.

ROMROD, or RUMROTH, a town, with a castle, of Westphalia, in the principality of Hesse; 16 miles E. of Marburg.

ROMSDAL, a town of Norway, and capital of a district or provostship, in the diocese of Drontheim; 100 miles S.S.W. of Drontheim. N. lat. 62° 23'. E. long. 7° 54'.

ROMSDAL Bay, a bay or river of the North sea, on the coast of Norway, 20 miles long, with several branches. N. lat. 62° 40'. E. long. 7° 45'.

ROMSEY, or RUMSEY, a market-town and parish in the lower half hundred of King's Sombourne, Andover division of the county of Southampton, England, is seated in a flat district, watered by the river Test, or Anton, at the distance of 8 miles S.W. from the town of Southampton, and 73 miles S.W. by W. from London. The town is of considerable antiquity, and probably derived its origin, as it certainly did its early importance, from an abbey founded here by Edward the Elder, and afterwards filled with Benedictine nuns by his successor, king Edgar. The first abbess of this monastery was Elæda, the daughter of a Saxon nobleman, named Ethelwold, who had greatly contributed to its original establishment, and whom some authors, therefore, designate as its founder. This lady was afterwards canonized, and constituted one of the patron saints of the abbey. She was succeeded in her office by several females of royal birth, and distinguished for the sanctity of their lives. In the year 992, Romsey and its monastery were plundered by the Danes; but the nuns and most of their valuables had been previously removed to Winchester, by order of the abbess Elwina. The buildings were soon restored, and the nuns replaced. In 1085, Christina, cousin to king Edward the Confessor, took the veil here, and was subsequently entrusted with the education of Matilda, daughter of Malcolm, king of Scotland, afterwards consort to Henry I. Mary, daughter to king Stephen, likewise became a nun in this abbey; but afterwards renounced the veil, and married Matthew, younger son of Theodoric, earl of Flanders; an event which called forth all the thunders of the Vatican against herself and her husband. The benefactors to this monastery were numerous; and previously to the dissolution, its revenues were estimated, according to Dugdale, at the annual value of 339*l.* 10*s.* 10½*d.*; but Speed states their amount at 528*l.* 8*s.* 10½*d.* Of the buildings which belonged to it scarcely a vestige remains, except the church, which is still used for divine service.

Romsey is governed by a corporation, consisting of a mayor, recorder, six aldermen, and twelve burgesses, besides inferior officers. The petty sessions for Romsey division of the hundred are held here. The market-day is Saturday, weekly; and there are fairs on Easter Monday, every Tuesday fortnight after 31st July until Christmas, 26th August, and 8th November. Formerly this town possessed a considerable woollen trade, but that is now greatly diminished, and is in part supplied by paper-works, and a packing manufactory. The chief public buildings here are the audit-house, which is a large square building, standing on the pier, near the centre of the town; a town-hall; the parish church; and a large meeting-house for Presbyterians, built about ten years ago. The church, which alone de-

erves particular notice, was formerly annexed to the abbey. The whole presents a series of interesting studies and details to the architectural antiquary. It consists of a nave, with aisles, a north and south transept, a choir, or chancel, with aisles, three small chapels or oratories at the east end, where is also an aisle, two small semicircular chapels at the angles of the transepts with the choir, and a low tower rising on four lofty arches, at the intersection of the transepts with the nave and choir. The eastern part of the church is certainly the most ancient, and is said by Dr. Latham to have been erected anterior to the Norman conquest. At the west end are some arches of a later age, probably about the era of king Stephen. In the south transept is an ancient statue of a female, probably one of the nuns. Near the south door is a crucifixion in bold basso relievo, close to which is a square niche, or cupboard, in the wall. At the east end of the north and south aisles of this church are two pillars, the sculptures on the capitals of which form the subject of some papers in the 14th and 15th volumes of the "Archæologia." That in the north aisle exhibits four human figures, besides two birds, a horse, and several mutilated bodies, &c.; the whole representing a field of battle. Two of the human figures are crowned, and one of them holds the other by the beard. Both have swords in their right hands, and seem in the act of striking with them; but each is restrained by a winged figure seizing his sword. To the right, at bottom, is a horse saddled; and in each corner, above, a bird of prey, loaded with mangled limbs, many of which are likewise dispersed in various places. The opposite pillar to this represents a more peaceable scene. In the centre stands a crowned personage in a loose robe. On the left is another crowned man, sitting bare-legged, and supporting one side of an angular label, the other side of which is held by a winged figure; and on the right is a similar label, held by two sitting figures habited in mantles. The legend on the first label is "Robert mefec'"; and that on the second, "Robert tute confule + D.S." Dr. Latham makes the former refer to the battle and consequent peace between king Alfred and Guthrum, the Danish chief, who opposed him; and the latter to the foundation of the monastery. The figures of the two kings he supposes to represent Edward and Edgar; and the legend to mark the name of the consularius, or master mason of the buildings. Other capitals in this church are also ornamented with sculptured figures, &c. (See Carter's "Ancient Sculpture and Painting," folio.) Some ancient tomb-stones commemorate the names of abbesses buried beneath; and there is also a flat stone in remembrance of the celebrated sir William Petty, author of "A Treatise on Taxes and Contributions," "A Survey of Ireland," and several other works, who died in 1687. He was the son of a clothier at Romsey, and ancestor to the present marquis of Landisdown. Another eminent native of this town was Mr. Giles Jacob, author of Jacob's Law Dictionary, and of a work, entitled "Lives and Characters of English Dramatic Poets." According to the parliamentary returns of 1811, Romsey parish, including Romsey Infra et Extra, contained 933 houses, and 4297 inhabitants.

About half a mile to the south-west of Romsey is Broadlands, the seat of lord viscount Palmerston, whose father, the late lord, purchased it from the family of St. Barbe, which had possessed it for more than two centuries. The house is embellished with a fine collection of paintings, by the most eminent masters. Paultons, a seat of lord viscount Mendip, is situated about three miles to the south-east. The house is not remarkable, but the grounds, which extend five miles in circumference, display the taste and skill of the celebrated Brown. Near this mansion is Tatchbury

Mount, which tradition reports to have been the scite of a royal hunting feat; but it appears more probable that it has been an ancient military station. The vallations are still clearly discernible on the declivity of the hill. Beauties of England and Wales, vol. vi. 8vo., by John Britton and E. W. Brayley. Archæologia, vols. xiv. xv.

ROMSOE, a small island of Denmark, in the Great Belt, near the coast of Funen. N. lat. 55° 30'. E. long. 10° 48'.

ROMULEA, in *Botany*, a name given by Maratti, in honour of the founder of Rome, to the Linnæan *Ixia Bulbocodium*; which Mr. Ker, in separating with other species, from *Ixia*, has thought proper to call *Trichonema*; nor shall we, by any means, contend for the above, though the original appellation of this genus. See TRICHONEMA.

ROMULUS, in *Biography*, founder and first king of Rome. See ROME.

ROMULUS, in *Geography*, a military township in the state of New York, in Cayoga county, between Seneca and Cayoga lakes. Its northern part is crossed by the road to the ferry at Cayoga lake. The township was incorporated in 1794, and comprehends, within its jurisdiction, the townships of Janus and Galen, and that part of the lands referred to the Cayoga nation of Indians, W. of Cayoga lake. Its number of inhabitants is 1025.

ROMUNDA, a mountain of Carinthia; 6 miles S. of Mautten.

RON, a small rocky island of Denmark, in the Little Belt. N. lat. 55° 7'. E. long. 9° 55'.

RON, *Lynder*, a cluster of small islands in the Categat; 12 miles S. from the island of Lesoe.

RONA, one of the western islands of Scotland, is situated about sixteen leagues N.W. from the Butt of Lewis, and is supposed to lie farthest to the N.W. of any land in Europe. It is about a mile in length, and half a mile in breadth; and is included in the parish of Barvas, in the isle of Lewis. In this island is an ancient chapel, which is fenced round with a stone wall, and is kept clean and in good repair by the inhabitants. On the altar lies a large plank of wood about ten feet long, having as many holes in it, each pegged with a stone, to which the natives ascribe many virtues, particularly the promotion of speedy delivery to a woman in travail. The products of Rona are a few cows and sheep, and a small quantity of barley and oats. The custom of walking round a person sunways, to whom it is intended to express high esteem, is yet practised by the natives of Rona, all of whom are employed as servants by the tacksmen of the island, which was let on lease about fifteen years ago for the annual rent of four pounds. A Description of the Western Islands of Scotland, by M. Martin, 1716, 8vo. Carlisle's Topographical Dictionary of Scotland, 4to. 1813. The Statistical Account of Scotland, &c. by sir John Sinclair, bart. vol. xix. Edin. 8vo. 1797.

RONABEA, in *Botany*, an unexplained name, Aubl. Guian. v. 1. 154. t. 59. Just. 205. Lamarck Illustr. t. 166. This supposed genus appears, as Jusseu points out, so very near *PEDERIA*, see that article, that we cannot consider them as distinct. Still, without examination of specimens, we durst not positively treat of it under that head. Aublet describes two species, *R. latifolia* and *erecta*; shrubby plants of Guiana, of no remarkable properties, the first with a twining stem, the other erect. The flowers are small and axillary.

RONALDSAY, NORTH, in *Geography*, the most northerly of the Orkney islands, Scotland, is so called to distinguish it from South Ronaldsay, the subject of the next article, to which, however, it bears no sort of resemblance.

It is separated from the isle of Sanday by a rapid and dangerous frith, two miles in breadth, and contains an area of four square miles in extent, which supports about 500 inhabitants. The whole island is flat, and little raised above the level of the ocean, which rendered it peculiarly dangerous to navigators, previous to the erection of a lighthouse on its north-eastern extremity. It is nevertheless dry and healthy, and produces both corn and grafs of excellent quality, and sufficient to supply the home consumption. The inhabitants are sober, honest, and industrious, beyond the generality of the Orkney islanders. In winter, their chief occupation is the care of their cattle and crops, and fishing, when the weather will permit their venturing to sea. In spring they are employed on the land, as in other places; and when summer arrives, almost every individual is actively engaged in the manufacture of kelp, of which they make about 120 tons every year. Near the centre of the island is a single stone monument, ten feet high, and four broad, round which it is customary for the inhabitants to assemble annually, on the first day of January, to usher in the new year with the song and the dance. Tumuli are numerous, one of which, on being opened, "was found to contain a building of nine feet in diameter, circular on the outside, and square and hollow within, in the bottom of which was a well, and in the upper part the skeleton of a man in nearly an upright attitude." History of the Orkney Islands, by the Rev. Dr. Barry; second edition, by the Rev. James Headrick, 4to. Lond. 1808.

RONALDSAY, *South*, one of the Orkney islands, Scotland, is situated to the southward of the Mainland of Orkney, at the distance of seven miles from Duncansby Head, in Caithness. In superficial extent it contains about eighteen square miles; and its inhabitants amounted to 1631 in the year 1811. The greater part of this island is very well cultivated; and is equally fit for corn and pasture. Of the former, a larger quantity is raised than can be consumed at home, and hence a considerable exportation takes place to the Mainland. The bowels of the earth contain lead ore, of which a very promising vein has been discovered at Grimness Head, and another at Widewall. The shores abound with kelp, which is a source of great wealth to the inhabitants; and the sea affords fish in vast numbers, and of the best quality. An English company employs about twenty vessels in carrying cod-fish and lobsters to the London market. This island is excellently furnished with harbours: for, besides several places where ships may anchor for a time, it has the safe and commodious road of St. Margaret's Hope on the north, and the bay of Widewall on the south. Here are also some interesting objects of antiquity. On the summit of a hill, near Stow's Head, are the remains of a monument composed of three upright stones, placed in a triangular form, but only one of them is now standing. Another stone monument is situated in the beautiful vale of Paplay. It consists of a single block of stone, sixteen feet high, and destitute of all marks of human art, by which to discriminate its use. Similar stones of smaller dimensions may be seen in other parts of the island, which likewise affords a number of tumuli, and several of those buildings usually called Picts-houses; also the ruins of some Catholic chapels and chantries. History of the Orkney Islands.

RONAY, one of the western isles of Scotland, is situated between the Mainland and the Isle of Skye. It is about four miles in length, and two in breadth; and has a more level surface, and greater fertility of soil, than most islands of the Hebrides; but its cultivation is much neglected. On the western side of the island is an excellent harbour for shipping; and round the coast the sea has hollowed out several caves, some of which afford fine specimens

of stalactites. Carlisle's Topographical Dictionary of Scotland, 4to. 1813. Sinclair's Statistical Account of Scotland, vol. xvi. 8vo.

RONCA *de Scaglia*, a town of Italy, in the department of the Panaro; 20 miles S. of Modena.

RONCADOR, an island in the Caribbean sea. N. lat.  $13^{\circ} 45'$ . W. long.  $79^{\circ} 30'$ .

RONCATOR, or *Rum Key*, one of the smaller Bahama islands. N. lat.  $23^{\circ} 26'$ . W. long.  $75^{\circ} 3'$ .

RONCAGLIA, FRANCESCO, in *Biography*, an Italian opera singer, with a soprano voice, who arrived in England in 1777 as first man in our lyric theatre, when Sacchini was here, and the Danzi, afterwards madame Le Brun, was first woman.

Roncaglia had a beautiful face, and elegant figure; a sweet-toned voice; a chaste and well-disciplined style of singing; hazarded nothing, and was always in tune. The best part of his voice, which was a soprano, was from D to A; he sometimes went to C, but not easily. Both his voice and shake were feeble; and of the three great requisites of a complete stage singer, pathos, grace, and execution, which the Italians call *cantabile*, *graziosa*, and *bravura*, he was in perfect possession of only the second. As his voice, though of an exquisite quality, was by no means powerful, and little more than a *voce di camera* (more suited to a room than a spacious theatre), his singing at concerts, when confined to the *graziosa* style, left nothing for an audience to wish. He was of the Bologna school, formed by Pistocco and Bernacchi, and reminded his hearers of one of their best scholars, Guarducci.

Roncaglia remained here two seasons, and was succeeded by Pacchierotti.

RONCAGLIA, in *Geography*, a town of Italy, in the duchy of Piacenza; 8 miles E. of Piacenza.—Also, a town of the county of Tyrol; 14 miles N.E. of Trent.

RONCARUOLO, a town in the duchy of Piacenza; 4 miles E.N.E. of Piacenza.

RONCAU, a town of the island of Dominica.

RONCEVALLOS, a town of Spain, in Navarre, situated in a valley of the same name, between Pamplona and St. Jean Pie de Porte. This valley has been celebrated in romance for the defeat of the emperor Charlemagne, and the death of Roland; 14 miles N.N.E. of Pamplona.

RONCHAMPS, a town of France, in the department of the Upper Saone; 5 miles E. of Eure.

RONCHAUX, a town of France, in the department of the Doubs; 3 miles S. of Quingey.

RONCIGLIONE, a town of Italy, and capital of a county, to which it gives name, in the Patrimonio; 10 miles S. of Viterbo. N. lat.  $42^{\circ}$ . E. long.  $12^{\circ} 8'$ .

RONCINA, a town of Austria, in the county of Goritz; 5 miles N. of Goritz.

RONCO, a town of the Ligurian republic; 15 miles N. of Genoa.

RONCOFERRATO, a town of Italy, in the department of the Mincio; 7 miles E. of Mantua.

RONCOFREDDO, a town of Italy, in the department of the Rubicon; 9 miles W. of Rimini.

RONDA, a town of Spain, in the province of Grenada, situated on a fertile spot, which supplies Cadiz with all kinds of fruit and vegetables. The soil, which is of a reddish colour, abounds with pebbles, and resists the action of fire; and it is therefore used in furnaces for fusing iron. The adjacent country is famous among other curiosities for that species of Viverra, called Genette (see VIVERRA); and also for wild bulls, wolves, and other ferocious animals: its rocks serve also as a retreat for eagles, ospreys, and kites; 35 miles W. of Malaga. N. lat.  $36^{\circ} 45'$ . W. long.  $5^{\circ} 15'$ .

RONDE,

RONDE, or RHONDS, a small island of the West Indies, near the north coast of the island of Grenada. It has about 500 acres of excellent land, employed in pasturage, and the cultivation of cotton.

RONDE *Haye, La*, a town of France, in the department of the Channel; 6 miles N. of Coutances.

RONDE, Fr., in *Music*, a semibreve. See *TIME-TABLE*, and *Musical CHARACTERS*.

RONDE *de Table*, Fr. a kind of *chançon à boire*, or drinking song, with a *refrain*, or burden to it, and generally mixed with sentiments of gallantry, composed of different stanzas, which are sung by turns at table, and in which all the guests join chorus in the refrain.

RONDEAU, Fr., an air of two or more strains, always returning to, and finishing with the first. In order to do this in an artful, pleasing manner, the modulation should pass into some key relative to that of the first strain.

Rousseau has very justly censured the writing and setting vocal rondeaus, in which the thought is begun in one strain, and continued or ended in another; or begins with a simile, of which the application is made in the second strain.

The term *rondeau*, derived from *rondel*, is of great antiquity in France. In old English it was called a *roundelay*.

But Rousseau, after pointing out poetical and musical defects in the composition of *rondeaux*, indicates the means of avoiding both. "Whenever a sentiment, expressed in the first strain, suggests a reflexion which confirms and enforces it in the second; whenever a description of the singer's state of mind is the subject of the first strain, and illustrates a simile in the second; whenever an affirmation in the first strain, contains its proof and confirmation in the second; every time, in short, that the first strain contains a proposition to perform some action, and a reason for it is given in the second; in these, and similar cases, a *rondeau* will be always well placed."

RONDEL, in *Fortification*, a round tower, sometimes erected at the foot of a bastion.

RONDELETIA, in *Botany*, was so named by Plumier, in memory of William Rondelet, a physician of Montpellier, who died chancellor of that university in 1566, aged fifty-nine. He is most celebrated for his work on Fishes; but his studies were much directed to Botany, so far as concerned the *Materia Medica*; and he is said to have deeply investigated the writings of Dioscorides.—Plum. Gen. 15. t. 12. Linn. Gen. 90. Schreb. 120. Willd. Sp. Pl. v. 1. 930. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 366. Swartz Obf. 66. t. 10. f. 2. Juss. 201. Lamarek Illustr. t. 162. (Lightfootia; Schreb. 122.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Stellata*, Linn. *Rubiaceae*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, superior, in five deep, acute, permanent segments. *Cor.* of one petal, funnel-shaped; tube cylindrical, longer than the calyx, very slightly inflated at the summit; limb flat, somewhat reflexed, in five deep roundish segments. Nectary a crenate ring in the orifice. *Stam.* Filaments five, awl-shaped, inserted into the middle of the tube; anthers simple. *Pist.* Germen roundish, inferior; style thread-shaped, as long as the corolla; stigma cloven. *Peric.* Capsule roundish, crowned with the calyx, of two cells. *Seeds* two or more in each cell, rarely solitary.

Ess. Ch. Corolla funnel-shaped, nectariferous at the mouth. Capsule of two cells, with several seeds, roundish, inferior, crowned with the calyx.

A genus of West Indian, simple and entire-leaved, shrubs, to which the discoveries of Swartz have added several species. Three only are mentioned in the *Hortus Kewensis*,

nor are any of them in general cultivation, though some possess fragrance as well as elegance. Two have four-cleft tetrandrous flowers. Jussieu terms the fruit a berry, which seems incorrect. *Rondeletia asiatica*, Linn. Sp. Pl. 244, is perhaps an *Ixora*, or *Pavetta*.

1. *R. americana*. Corymbose *Rondeletia*. Linn. Sp. Pl. 243. Willd. n. 1. Ait. n. 1. (*R. arborescens*, tini facie; Plum. Ic. 237. t. 242. f. 1.)—Leaves elliptic-lanceolate, acute. Panicles repeatedly forked, on long stalks, rising above the stem.—Native of the West Indies. Cultivated by Miller, before the year 1752. Mr. Aiton says it flowers in the stove in August. We have seen no specimen, neither had Linnæus. His description is taken from Plumier's figure, as follows. "A shrub, with opposite, sessile, lanceolate leaves. Common flower-stalks solitary, very long, naked, forming at the top a forked corymbus, in each of whose subdivisions is a sessile flower, with a two-leaved involucre;" more properly a pair of bractæ. The flowers are very numerous, about an inch long. Leaves not quite sessile, somewhat deflexed, entire, two or three inches long, and one or one and a half broad.

2. *R. odorata*. Fragrant *Rondeletia*. Jacq. Amer. 59. t. 42. Linn. Sp. Pl. 1671. Willd. n. 2. Swartz Obf. 67. (*R. obovata*, by an error of transcription; Linn. Syst. Nat. ed. 12. v. 2. 163.)—Leaves ovate, bluntish, rough; somewhat heart-shaped at the base; on short stalks. Flower-stalks cymose, three-cleft, terminal. Native of the West Indies, but rare. Swartz. Jacquin found it in rocky places, near the sea, at the Havannah, bearing flowers, as well as ripe seeds, in January. The habit of this shrub is inelegant and straggling; its height six feet; the young shoots villous. Flowers in terminal tufts, each tuft about two inches broad; their smell very sweet, resembling violets. The corolla has often six segments, though the stamens are never more than five; its colour is vermilion, with an orange nectariferous ring.

3. *R. hirta*. Hairy *Rondeletia*. Ait. Hort. Kew. ed. 1. v. 1. 227. ed. 2. n. 3. Willd. n. 13. Swartz Ind. Occ. v. 1. 373.—Leaves oblong, pointed, hairy, rigid; ribbed beneath. Flower-stalks axillary, three-forked, erect.—Native of Jamaica, from whence it was imported about the year 1776, by John Blackburne, esq. of Orford, Lancashire. It blooms in the stove in summer. This is said in Hort. Kew. to be very nearly akin to *R. odorata*, differing merely in its axillary inflorescence; larger, more acute, leaves, not rough on their upper surface, nor scarcely heart-shaped at the base; and longer footstalks. The tube of the corolla is but twice the length of the calyx. Style prominent beyond the mouth. Stigmas erect, converging. Corolla reddish-yellow. Swartz says there are only two seeds perfected, of a hemispherical figure, and that the footstalks are short and hairy. His description agrees in other respects with Mr. Aiton's.

4. *R. levigata*. Smooth-leaved *Rondeletia*. Ait. n. 2.—Leaves stalked, elliptical, acute, very smooth, except the rib underneath. Stipulas elliptical, membranous, smooth. Panicles three-forked, axillary, somewhat hairy.—Native of the West Indies, flowering in our stoves in spring or summer. It was introduced, in 1790, by Mr. William Anderson. The stem is shrubby, spreading, with forked round branches, slightly hairy when young. Leaves two or three inches long, acute at each end, rather fleshy; very smooth above; paler beneath, with a reddish, sometimes hairy, rib and veins. Stipulas very large, elliptical, obtuse, reddish. Flowers reddish, small, their tube scarcely longer than the limb. Base of the calyx clothed with long hairs.

5. *R. trifoliata*. Three-leaved *Rondeletia*. Linn. Sp. Pl.

## RONDELETIA.

Pl. 1671. Willd. n. 3. (*R. trifolia*; Jacq. Amer. 60. t. 43. "R. arborefcens, tini facie; Ehret Pict. t. 15.")—Leaves on long hairy stalks, whorled, lanceolate, acute; somewhat downy beneath. Stipulas pointed. Panicles axillary, compound, hairy.—Native of Jamaica, flowering in February.—An upright tree, twelve feet high. Young branches obtusely triangular, hairy. Leaves three in a whorl, lanceolate, acute, entire, three inches long; smooth above; slightly downy beneath; with hairy footstalks. Stipulas roundish, pointed, ternate, alternate with the leaves. Clusters axillary, one inch and a half or more in length, hairy, unequal, branched. Flowers inodorous, small, reddish, sessile or stalked. Fruit not examined. Jacquin.—On comparing Browne's specimen of his *Petesia*, t. 2. f. 3, with Jacquin's plate and description of this *Rondeletia*, we are persuaded they must be the same thing. Consequently the *Ixora americana* of Linnæus, an ambiguous and obscure plant, ought to be expunged, and referred hither. (See *IXORA*, n. 11.) Swartz quotes this synonym of Browne for his *racemosa*, (see the following); but a comparison of specimens shews them to be distinct, though very nearly akin.

6. *R. racemosa*. Smooth Racemose *Rondeletia*. Swartz Ind. Occ. v. 1. 360. Willd. n. 7, excluding Browne's synonym.—Leaves on long smooth stalks, ovato-lanceolate, pointed, smooth on both sides. Stipulas abrupt, pointed. Clusters axillary, three-forked, spreading, smooth.—Native of uncultivated hills in Jamaica. Like the last in habit, but the leaves are opposite, more coriaceous, and quite smooth, as well as the footstalks and flower-stalks. The stipulas are fringed, like the bractæas and calyx. Corolla externally finely downy, as in Browne's specimen just alluded to under *R. trifoliata*.

7. *R. virgata*. Long-branched *Rondeletia*. Swartz Ind. Occ. 354. Willd. n. 4.—"Leaves heart-shaped, roundish. Branches spreading, thread-shaped. Flower-stalks three-cleft. Flowers three together, crowded. Stamens four."—Gathered by Swartz in bushy places, near the sea, in the northern part of Hispaniola, flowering and fruiting in December.—A shrub about six feet high, with very long, spreading, alternate, rough-barked twigs. Leaves half an inch long, on short stalks, somewhat reflexed, very smooth. Stipulas minute, acute. Flower-stalks axillary and terminal, opposite, elongated and erect, resembling branches, and often bearing a pair or two of leaves, three-cleft; the terminal ones leafless, and bearing but three flowers. Flowers terminal, brownish-purple, silky at the outside; four-cleft, with four very short stamens. Seeds several, minute, compressed.

8. *R. pilosa*. Hoary *Rondeletia*. Swartz Ind. Occ. v. 1. 356. Willd. n. 5. (*R. triflora*; Valil. Symb. v. 3. 34. t. 54.)—Leaves ovato-lanceolate, hairy on both sides. Flower-stalks axillary, shorter than the leaves, three-flowered. Stamens four.—Native of the West India islands, of Santa Cruz, and Montserrat. A shrub, whose young branches, leaves, stalks, calyx, and outside of the corolla, are clothed with fine, soft, hoary pubescence. Leaves on still more hairy footstalks, elliptic-lanceolate, with a small acute point, two or three inches long, ribbed; paler, or glaucous, beneath. Flower-stalks opposite, axillary, rather shorter than the leaves, hairy, each bearing three flowers, of which the middlemost has the shortest partial stalk. Bractæas, and segments of the calyx, long, awl-shaped. Corolla four-cleft; somewhat downy within, but moist without. We have no account of the colour, as Swartz seems not to have gathered this species himself. The dried flowers are brown, with some indication of a tawny hue.

9. *R. thyrsoides*. Tufted *Rondeletia*. Swartz Ind. Occ. v. 1. 358. Willd. n. 6.—Leaves oblong, acute, membranous; downy beneath. Stipulas ovate, acute, smooth. Clusters axillary, dense, many-flowered.—Native of dry barren hills, in the western part of Jamaica, flowering in May. A smooth, branching shrub, six feet high, with long, spreading, bluntly quadrangular twigs. Leaves three inches long, acute at each end, ribbed, veiny; smooth above. Footstalks an inch long, striated. Stipulas close-pressed, broad, ovate, acute, smooth, rigid. Clusters dense, oblong, shorter than the leaves, on smooth stalks, their branches opposite, crossing each other, subdivided; the last usually three-flowered. Flowers small, yellowish-white, or rusty-coloured, highly fragrant at night. Bractæas minute, awl-shaped. Calyx very minute, five-toothed. Corolla five-cleft, with five stamens. Seeds two in each cell, rounded, somewhat angular, striated.

10. *R. laurifolia*. Laurel-leaved *Rondeletia*. Swartz Ind. Occ. v. 1. 363. Willd. n. 8, excluding Browne's synonym.—"Leaves lanceolate-oblong, acute, smooth on both sides. Stipulas deltoid. Clusters axillary, compound, erect. Tube of the corolla very short."—Grows in bushy places in Jamaica.—Branches round, smooth. Leaves laurel-like, three or four inches long, ribbed, veiny; paler beneath. Footstalks an inch long, smooth, flat on the upper side. Stipulas broad, combined, deltoid, pointed, spreading, rigid, downy at the edge. Clusters often as long as the leaves, compound, their ultimate divisions mostly three-flowered. Bractæas very minute. Flowers small, brownish-yellow, five-cleft. Seeds in an early state numerous, membranous, but two only arrive at maturity, which are hemispherical.—We cannot but dissent from our learned friend professor Swartz, in his citation of Browne's t. 2. f. 2, and consequent remarks. That plate certainly represents the *Petesia stipularis* of Linnæus, which was described from Browne's own specimen, and the leaves are, on both sides, finely downy, though no such character is expressed in the engraving. The inflorescence is thyrsoid, and not half so long as the leaves. See the next species.

11. *R. tomentosa*. Downy-leaved *Rondeletia*. Swartz Ind. Occ. v. 1. 365. Willd. n. 9. (*Petesia stipularis*; Linn. Sp. Pl. 160. P. fruticosa, foliis ovatis oppositis, &c.; Browne Jam. 143. t. 2. f. 2.)—Leaves elliptic-lanceolate, pointed, downy. Flower-stalks three-forked, axillary, much shorter than the leaves.—Native of stony hills in Jamaica, near the shady road called Sixteen-mile walk, not far from Spanishtown. Swartz. A specimen from the author shews this to be precisely the above plant of Linnæus and Browne, as Swartz suspected. We refer the reader to *PETESIA* for its description, and for remarks on the uncertainty of that genus, which perhaps must hereafter be sunk in *Rondeletia*.

12. *R. umbellulata*. Umbellate *Rondeletia*. Swartz Ind. Occ. v. 1. 367. Willd. n. 10.—Leaves elliptic-lanceolate, acute, somewhat hairy. Stipulas ovate, pointed, membranous, hairy. Flower-stalks axillary, three-forked. Flowers somewhat umbellate.—Native of rocky banks of rivers in Jamaica, flowering in April. Swartz. That author suspects his plant may be the same with Browne's third *Petesia*, which we have adopted by the name of *villosa*, n. 4. This may possibly be the case; but having no specimen of what Browne intended, we cannot determine the point. Swartz's plant, communicated by himself, is a branching upright shrub, two feet or more in height; the branches smooth, somewhat compressed; hairy and leafy at the summit. Leaves about three inches long, clothed with short scattered hairs, and supported by hairy stalks, half

an inch in length. *Stipulas* large, concave, most hairy within, with a taper reflexed point. *Flower-stalks* not half the length of the leaves. *Flowers* collected into a sort of round head. *Brañeas*, and segments of the *calyx*, lanceolate, hairy. *Corolla* larger than in some of the foregoing, brownish-yellow. Two seeds are perfected in each cell.

13. *R. incana*. Silvery-cupped *Rondeletia*. Swartz Ind. Occ. v. 1. 369. Willd. n. 11.—Leaves ovato-lanceolate; rough and hoary beneath. Stalks axillary, simple, three-flowered. Segments of the calyx ovate, silky on both sides.—Found by professor Swartz, from whom we have a specimen, on calcareous rocky mountains of Jamaica, but rarely. A *shrub*, two or three feet high, with round, rigid, rough branches. Leaves about the extremities of the branches, three inches long, somewhat coriaceous; smooth and shining above; palish and hairy or downy beneath, with a prominent hairy rib and veins. *Footstalks* stout, silky, three-quarters of an inch long. *Stipulas* very short, fringed. *Flower-stalks* axillary, opposite, twice the length of the footstalks, each bearing three large, nearly sessile flowers, whose globular germen, and large ovate segments of the *calyx*, are entirely clothed with long, dense, silky hairs; as are also the lanceolate *brañeas*.

14. *R. hirsuta*. Rough *Rondeletia*. Swartz Ind. Occ. v. 1. 371. Willd. n. 12.—Leaves oblong, acute, hairy. Stalks axillary, three-forked, lax. Flowers hairy.—Native of bushy hills, in the south part of Jamaica, blossoming in January. A *shrub* six feet high, with a smooth stem, and rough, lax, slightly compressed branches. Leaves on short, hairy, reddish stalks, oblong, broadish in the middle, ribbed, veiny, hairy on both sides, pale beneath. *Stipulas* broad, ovato-lanceolate, long and hairy. *Flower-stalks* opposite, slender, about the length of the leaves, twice three-cleft, lax, hairy. *Flowers* stalked, yellowish, externally hairy. *Brañeas* minute, linear, acute, hairy. Differs from *hirta*, n. 3, in having less rigid leaves, with lax, not stiff, branches and *flower-stalks*. Swartz. We have seen no authentic specimen; for one marked *hirsuta*, by the younger Linnæus in his herbarium, seems rather to be Swartz's *hirta*. The descriptions of these two species are not at all well contrasted.

The division of this genus into two sections, by the number of the seeds, is better omitted, as it separates species most nearly akin, and is besides very uncertain. All have the rudiments of several seeds in each cell of the germen, though a greater or less number is perfected in some than in others, or rather perhaps, according to circumstances, in the same.

*RONDELETIA*, in *Gardening*, contains plants of the woody, exotic, stove kind, of which the species cultivated is the American *rondeletia* (*R. americana*).

*Method of Culture*.—This plant may be increased by sowing the seeds on a moderate hot-bed in the early spring, and when the plants have attained a little growth they should be removed into separate pots, being plunged in the bark-bed of the stove, where they are to remain and be managed as other tender exotic plants of a similar kind. They afford variety in stove collections.

*RONDENCHE*, in *Geography*, a town of Russia, in the government of Riga; 28 miles S.W. of Narva.

*RONDERO BAY*, a bay on the N.E. coast of Antigua. N. lat. 17° 15'. W. long. 61° 26'.

*RONDINE*, in *Ichthyology*, a name by which some authors have called the *milvus*, or flying-fish.

*RONDINE Pescis*, a name by which some have called the *hirundo piscis*, or swallow-fish, called by others *mugil alatus*.

*RONE*, in *Geography*, a small island near the W. coast of Scotland. N. lat. 58° 26'. W. long. 4° 55'.

*RONEBY*, a town of Sweden, in the province of Blekingen; 10 miles W. of Carlscrona.

*RONES*, a cape on the W. coast of the island of Jersey; 6 miles N.N.W. of St. Helice.

*RONGOS*, or *Pongos*, trumpets, or rather French horns, of the kingdom of Loango, in Africa. These instruments are made of ivory, and resemble hunting-horns of the ancients: their widest diameter at the mouth is an inch and a half, or two inches; they are of various kinds, and probably serve for treble and base to each other. It is pretended, that many rongos united produce a very harmonious effect. (Supplement to the folio Encyclopédie.) The editor of the article forgot that, out of Europe, treble and base performing together, except in octaves, is unknown, and that harmonious effects can be no otherwise produced.

*RONNE*, in *Geography*, a river of France, which rises about a league N. of Leuze, and runs into the Scheldt, between Tournay and Oudenarde.

*RONNE*, or *Ronde*, a sea-port town of Denmark, in the island of Bornholm, the residence of the governor. The harbour is not deep, but well fortified.

*RONNEBURG*, a town of Saxony, in the principality of Altenburg; 12 miles S.W. of Altenburg. N. lat. 50° 48'. E. long. 12° 5'.

*RONNEBY*. See *ROTNEBY*.

*RONNEN*, a small island of Denmark, near the N.W. coast of the island of Laland. N. lat. 56° 5'. E. long. 11° 15'.

*RONNSKAR*, a small island on the W. side of the gulf of Bothnia. N. lat. 65° 3'. E. long. 18° 24'.—Also, a small island on the E. side of the same gulf. N. lat. 63° 29'. E. long. 22° 2'.

*RONO*, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 5'. E. long. 18° 24'.

*RONOBO*, a river of the island of Celebes, which runs into Sewa bay. N. lat. 1° 33'. E. long. 120° 46'.

*RONOUMENA*, a river of Madagascar, which runs into the sea at Port St. James.

*RONSARD*, PETER DE, in *Biography*, a French poet of considerable celebrity, was born in the year 1524, of a noble family, in the Vendomois. He was educated at the college of Navarre in Paris; but he quitted his studies at an early age, and entered into the service of the duke of Orleans. From the service of this prince he was transferred to that of James V. of Scotland, who had married Magdalen of France. With this sovereign he passed two years, partly in Scotland, and partly in England; and then returning to France, was again taken into the employment of the duke of Orleans. He accompanied Lazare du Baif to the diet of Spire, who inspired him with such a taste for the belles lettres, that he applied himself with assiduity to the Greek language. He at length entirely devoted himself to poetry, by which he obtained the title of the prince of the poets of his time. He obtained the first prize at the floral games of Toulouse, and the ordinary recompence being thought unequal to his merit, he was presented by the city with a Minerva of massy silver. He was patronized by five successive kings of France, especially Charles IX., who maintained a poetical correspondence with him. Mary, queen of Scots, who greatly esteemed him, made him a rich present. He had some benefices conferred upon him, though he was not in priest's orders; and he displayed great zeal in opposing those of the reformed religion, against whom he fought, in 1562, at the head of the Vendomois. Like many religious zealots, he made his faith stand in-

stead of morals, being deeply addicted to licentious pleasures, by which he brought on a premature old age. In the latter years of his life he was a penitent, and felt deep contrition for the licentiousness of his muse at an earlier period, and resolved for the future to confine himself to sacred subjects. He died in 1585, at the age of 61, and his memory was honoured by eulogies from many of the literary characters of the time. The compositions of Ronfard were odes, eclogues, epigrams, sonnets, hymns, and a poem, entitled "La Franciade." Ronfard had a very bad taste, which rendered him pedantic, and often obscure; but he possessed many excellent qualities as a poet, having warmth of temper, a vivid imagination, and great quickness of invention. Very few of his works remain; but three of the best have frequently been reprinted, *viz.* "La Promesse," "Hymne à l'Eternité," and "Les Quatre Saisons de l'Année."

Ronfard was praised by all the poets of his time, and still merits a part of their encomiums. Scaliger dedicated to him a work, as the first poet in France. He was handsome in person, well made, loved music passionately, sung agreeably, and was very liberal. He had a public and magnificent funeral; the service was set in florid or figurative counterpoint, animated by all kinds of instruments: it was sung by the children of the chapel-royal by order of the king, who regretted extremely the death of so eminent a personage, the ornament of his kingdom. After his interment, Dupéron pronounced his funeral oration. All that were great and illustrious at court and in the city attended; and the crowd was so great, that cardinal Bourbon, and many other princes and nobles, were obliged to return without being able to gain admission into the chapel of the college of Boncourt at Paris.

RONSBERG, in *Geography*, a town of Bohemia, in the circle of Pilsen; 8 miles W. of Teinitz.

RONSDORF, or RHEINSDORF, a town of the duchy of Berg; 12 miles S.S.E. of Duffeldorf.

RONSE. See RENAY.

RONSEL, a town of Germany, in the county of Mentz; 7 miles S.W. of Lunschede.

ROSENAC, a town of France, in the department of the Charente; 18 miles E. of Angoulesme.

ROO, in *Agriculture*, a provincial term signifying rough or coarse, in the way of pastures, or the crops on other sorts of land.

ROOAC, in *Rural Economy*, a provincial word used to signify a fog or mist. See ROAK.

ROOAH, in *Geography*. See REWAIL.

ROOHOAGA. See RIU's *Island*.

ROOD, a quantity of land, equal to the fourth part of an acre; and containing 40 square perches, or poles.

This is the statute rood by which land is usually at present measured; but there are local measures in many districts, in which both the rood and acre are considerably larger. See MEASURES.

In Scotland, the rood contains 40 square fells. See FALL.

ROODAUN, in *Geography*, a town of Hindoostan, in Oude; 22 miles N.W. of Allahabad.

ROODE, or WAVEREN, an extensive transmontane division of the district of Stellenbosch and Drakenstein, in Southern Africa, in the Cape district, lying behind the mountains of Drakenstein, and producing abundance of grain, pulse, fruits, and wine. The pass of Roode Sand is the only waggon-road in this division, and is distant from Cape town about 70 miles. In this division there is a small neat church, and a very comfortable parsonage-house, with

extensive vineyards, orchards, garden, and arable land; and contiguous to the church is a row of houses, the number of which has lately increased.

ROODLOFT, the gallery over the entrance into the choir, in our ancient cathedral and abbey churches; in the front of which, looking towards the west window, a large rood, or crucifix, was usually placed.

ROOE, LITTLE, in *Geography*, a small island among the Shetlands. N. lat. 60° 43'. W. long. 1° 35'.

ROOF, in *Architecture*, is that part of a building generally consisting of two sloping sides, which protects its contents or inhabitants from inclement seasons or weather.

The slope of the roof must be directed by the nature of the climate. The ancient Egyptians, Babylonians, Persians, as well as other Eastern nations, made their roofs quite flat. The Greeks, it would appear, were the first people who made roofs with a declination each way from the middle to the edges; and this was very gentle, the height from the ridge to the level of the walls not exceeding one-ninth or one-eighth part of the span, as may be seen by many ancient temples now remaining. But in northern climates, subject to rain and snow, the height of the ridge must be very considerable. In most old buildings in Britain, the equilateral triangle seems to have been considered as the standard, both in private and public edifices; and this pitch seems to have continued for several centuries, until the extinction of Gothic architecture. At the commencement of this period, the ridge was made somewhat lower, and the rafters were three-fourths of the breadth of the building. This was called the true pitch, and subsequently the square seems to have been considered as the true pitch. The heights of roofs were gradually depressed from the square to one-third of the width, and from that to a fourth, which now seems to be a very general standard. They have even been executed much lower. There are some advantages in high pitched roofs: they discharge the rain with greater rapidity, the snow continues to lie a much shorter time on the surface, and they are less liable to be stripped by heavy winds. Low roofs require large slates, and the utmost care in execution; but they have this advantage, that they are much cheaper, since they require shorter timbers, and of a much smaller scantling. The roof is one of the principal ties to a building, when executed with judgment: it binds the exterior walls to the interior, and to the partitions, which act like strong counterforts against them.

Roofs are of various forms, which depend on the nature of the plan, the law of the horizontal and vertical sections. The most simple form of a roof is that which has only one row of timbers, arranged in an inclined plane, which throws the rain entirely to one side. This form is called a shed-roof, or lean-too. But the most elegant roof for a rectangular building is that which consists of two rectangular planes, of equal breadth, equally inclined to, and terminating in a line parallel to, the horizon; and consequently the form of the roof is that of a triangular prism, each side being equally inclined to the plane of the wall-head. This form of roof is sometimes called a pent-roof.

When the form of the plan is that of a trapezium, and the wall-heads properly levelled, the roof cannot be executed on planes, so as to terminate in a level ridge. In this case, the sides, instead of being planes, are made to wind, in order to have the summit parallel to the horizon; but the most eligible method is to make the sides of the roof rectangular planes, inclosing a level space, or flat, in the form of a triangle or trapezium, at the summit of the roof.

Roofs, which are flat on the top, are said to be truncated.

## ROOF.

Truncated roofs are chiefly employed in order to diminish the height, so as not to predominate over that of the walls.

When all the four sides of the roof are formed by inclined planes, the roof is said to be hiped, and is, therefore, called a hiped roof: the inclined ridges, which spring from the angles of the walls, are called the hips. Roofs of this description are frequently truncated; and when the plan of the walls is in the form of a trapezium, the truncation of the roof becomes necessary.

Roofs which stand upon circular bases, and which have all their horizontal sections circular, and the centres of the circles in a straight line drawn from the centre of the base perpendicular to the horizon, are called revolved roofs.

When the plan of the roof is a regular polygon, or a circle, or an ellipse, and the horizontal sections are all similar to the base, and a vertical section a portion of any curve convex on the outside, the roof is called a dome.

In order to save the expence of lead in rectangular roofs, instead of the flat, a valley is sometimes used, which makes the vertical section in the form of the letter M, or rather an inverted W; and thus it is that this form of roof has obtained the name of an M roof.

Before we proceed to the construction of roofing, it will be necessary to shew upon what principles a body or piece of timber may be supported in various positions.

### *Theory and Practice of Roofs.*

#### PROP. I.

If a heavy body ABCD (*Plate XLII. fig. 3. Architecture,*) be suspended by any two inclined strings, DE and CF, in a vertical plane, a right line drawn through the intersection, perpendicular to the horizon, will pass through the centre of gravity of the body.

It is shewn by the writers on mechanics, that if any three forces act upon a point, or a body, their directions will tend to the same point, or be parallel to each other. It is well known that every body acts with its full force in one point only, *viz.* in its centre of gravity, and in a direction perpendicular to the horizon: therefore, if a body is sustained at E and F, it will revolve round these points, until the line GH, passing through the intersection, H, of the two strings, DE and CF, and the centre of gravity G, become perpendicular to the horizon.

*Cor. 1.*—Hence if any body be supported by two strings, it may also be supported by two planes perpendicular to these strings, provided that the two points of the body supported are in the direction of the strings; for every body, acting upon a plane, acts in a line perpendicular to that plane.

*Cor. 2.*—Hence, also, a body may be supported by two props in any two directions that may be supported by strings, provided that the surface of the body, at the points of contact, or the ends of the props, be planes at right angles to the strings.

*Cor. 3.*—Hence all the properties that have been demonstrated of three forces acting upon a body, supposed void of weight, will equally flow from a heavy body supported by two strings, by substituting the weight of the body for the middle force; and hence, if the direction of any force supporting a heavy body be given, the other may easily be found.

#### PROP. II.

Given the position in which a body should be placed, and the position of a plane supporting the body at one end,

to find the position of another plane to support it at another given point, and to find the pressure on the planes, the weight of the body being given.

Through the centre of gravity of the body draw a vertical line, and through any point on which the body rests on the given plane draw a line perpendicular to that plane, meeting the vertical line; from the intersection draw a line to the other point which is to be supported; from that point draw a plane at right angles to this line, which will be the direction of the plane required. And to find the intensity of the forces, take any distance on the vertical line to represent the weight of the beam from the intersection; then on that line, as a diagonal, complete a parallelogram, whose sides are in the directions of the lines, perpendicular to the supporting planes; and the side of the parallelogram, perpendicular to either plane, will represent the force on that plane.

#### *Example 1. Plate XLII. fig. 2.*

Let the body ABCD lie upon the top of the wall KC, at C, so as to touch the lower edge, BC, of the body, at that point C; it is required to find the direction of a plane that will support the lower end at B, and to find the pressure of the body on the wall and on the plane.

Through the centre of gravity, G, of the body draw the vertical line GF; draw CF perpendicular to CB, join FB, and draw BI perpendicular to FB, and BI is the direction of the plane required. On the vertical line GF, make FM to represent the weight of the body, and complete the parallelogram LMNF; then FN represents the force on the wall-head, in the direction FC; and FL the force acting perpendicular to the plane, or in the direction BF. But if the vertical and horizontal thrusts on the wall at C are required, draw NP perpendicular to FG, meeting it in P; then the force FN is resolved into two forces, FP and PN. PN represents the horizontal part of the force, *viz.* that which pushes the wall in a direction parallel to the horizon; and FP the other part, which tends to press it downwards in a direction perpendicular to the horizon.

#### *Example 2. Fig. 1.*

Let the sloping body, ABCD, be supported by a wall at its lower end, D, which coincides with the surface of the body, and let G be the centre of gravity; it is required to cut a notch out of the body, at the upper end C, so that it may rest upon the top of a wall, which is made to fit the notch, and to find the pressure on the walls.

Draw the vertical line GE, from D draw DE perpendicular to DC, join EC, and make CF at right angles to it; then the notch, HCF, being cut, the body, ABCD, will be at rest. Then to find the pressure on the walls, complete the parallelogram EIKL, having a given angle DEC, and its diagonal on the given line EG. Then if KE represent the weight of the body, IE will represent the pressure in the direction DE, upon the wall at D, and LD the pressure in the direction CE. The horizontal and perpendicular pressures upon each wall may be found, as in the preceding example, by resolving each of the forces, IE and LE, into two; one of which is perpendicular to the horizon, and the other parallel to it.

*Scholium.*—It must be observed in this example, that the notch, which is cut out at C, will remove the centre of gravity nearer to the lower end D, and consequently alter the slope CF; but as this can only be in a very small degree, the equilibrium will hardly be affected by it, when the notch is very small.

*Example*

*Example 3. Fig. 6.*

Let one of the corners of a sloping body, *ABCD*, rest upon the top of a wall at *D*, which is quite level; it is required to find the position of a notch, cut out of the upper end *C*, so that the body may rest upon a wall made to fit the notch.

Let the small part, *FCH*, be so cut, that *CH* may be parallel to the horizon, then the body will be supported by the two walls at *C* and *D*. For draw *DJ*, *GK*, and *CL*, perpendicular to the horizon, then these lines being produced, they may be supposed to meet at an infinite distance. To find the pressure on the walls: join *DC*, and produce the vertical line *KG* to meet it in *E*; then if *G* be supposed to be the weight of the body,

the pressure on *D* will be  $\frac{EC \times G}{DC}$ , and the pressure

on *C*,  $\frac{DE \times G}{DC}$ .

*Example 4. Fig. 5.*

Let the body *ABCD* lie with its upper end against the vertical face of a wall at *C*; it is required to find the position of a plane supporting the lower end *D*, so that the body may be at rest.

Draw the vertical line *GE*, and *CE*, perpendicular to the face of the wall *CL*; join *ED*, and draw *DF* perpendicular to *ED*, then *DF* is the position of the plane required. Complete the parallelogram *EHIK*; then the pressure on *D*, and on *C*, and the weight of the body, are to one another as *EH*, *EK*, *EI*.

*Example 5. Fig. 4.*

To support a body *ABCD* by two props at two given points, *E* and *I*, the direction of one of the props, *EF*, being given.

Draw the vertical line *GK*, produce *FE* to *K*, and draw *KIH*; and *IH* is the prop required. On the vertical line *GK*, take *KM* to represent the weight of the body; and on *KM*, as a diagonal, describe the parallelogram *KLMN*; then *KL* is the compression of the prop *EF*, and *KN* the compression of the prop *IH*.

In order to be understood by the reader, it will be necessary to explain such terms as are used in the subsequent part of the article, by way of definitions.

*Wall-plates* are pieces of timber laid on the wall, in order to distribute the pressure of the roof equally, and to bind the walls together. These are sometimes called raising-plates.

*Trusses* are strong frames of carpentry, generally of a triangular form, supporting the covering. They are disposed at equal distances, and are used when the expansion of the walls is too great to admit of common rafters alone, which would be in danger of being bent or broken by the weight of the covering, for the want of some intermediate support. They are variously constructed, according to the width of the building, the contour of the roof, and the circumstances of walling below, &c.

*Tie* is any piece of timber connected at its extremities to two others, acted upon by opposite pressures, which have a tendency from each other; or to extend the tie, as rope or chain.

*Straining-piece* is any piece of timber, connected at its extremities to two others, acted upon by opposite pressures, which have a tendency towards each other.

Hence a tie acts contrary to a straining-piece. A chain,

rope, or small bar of iron, may be used for the former; but the latter must always be inflexible, being in a state of compression.

*Principal rafters* are two pieces of timber in the sides of a truss, supporting a grated frame of timber-work over them, on which the slating or covering rests.

*Purlins* are horizontal pieces of timber, fixed upon the principal rafters.

*Tie-beam* is a horizontal piece of timber, connected to two opposite principal rafters; it answers a twofold purpose, viz. that of preventing the walls from being pushed outwards by the weight of the covering, and of supporting the ceiling of the rooms below.—N.B. The tie-beam, when placed above the bottom of the rafters, is called a collar-beam.

*Common rafters* are pieces of timber of a small section, placed equidistantly upon the purlins, and parallel to the principal rafters: they support the boarding to which the slating is fixed.

*Pole-plates* are pieces of timber resting on the ends of the tie-beams, and supporting the lower ends of the common rafters.

*King post* is an upright piece of timber in the middle of a truss, framed at the upper end into the principal rafters, and at the lower end into the tie-beam: this prevents the tie-beam from sinking in the middle.

*Queen-posts*, two upright pieces of timber framed below into the tie-beam, and above into the principal rafters, placed equidistantly from the middle of the truss, or its extremities.

*Strutts* are oblique straining-pieces, framed below into the king-posts or queen-posts, and above into the principal rafters, which are supported by them; or sometimes they have their upper ends framed into beams, which are too long to support themselves without bending.—N.B. Strutts are often called braces.

*Punchions* are short transverse pieces of timber, fixed between two others for supporting them equally, so that when any force is on the one, the other resists that force equally, and if one break, the other will also break. These are sometimes called studs.

*Straining-beam* is a piece of timber placed between two queen-posts at their upper ends, in order to withstand the thrust of the principal rafters.

*Straining-fill* is a piece of timber placed at the bottom of two queen-posts, upon the tie-beam, in order to withstand the force of the braces, which are acted upon by the weight of the covering.

*Camber-beams* are horizontal pieces of timber, made on the upper edge sloping from the middle towards each end, in an obtuse angle, for discharging the water. They are placed above the straining-beam in a truncated roof, for fixing the boarding on which the load is laid; their ends run three or four inches above the sloping plane of the common rafters, in order to form a roll for fixing the lead.

*Auxiliary rafters* are pieces of timber framed in the same vertical plane with the principal rafters, under and parallel to them, for giving additional support, when the extent of the building requires their introduction. These are sometimes called principal braces, and sometimes cushion rafters.

*Joggles* are the joints at the meeting of strutts with king-posts, queen-posts, or principal rafters; or, at the meeting of principal rafters with king and queen-posts: the best form is that which is at right angles to the strutts.

*Cocking*, or *cogging*, is the particular manner of fixing the tie-beams to the wall-plates: one method is by dovetailing, and the other is by notching the under side of the tie-beam,

# ROOF.

and cutting the wall-plate in a reverse form to fit it. This method is far preferable to the other, as it is not liable to be drawn, which the other is very subject to, when the timber shrinks.

*Ridge-tree* is a piece of timber fixed in the vertex of a roof, where the common rafters meet on each side of it; the upper edge of it is higher than the rafters, for the purpose of fixing the lead which goes over it to cover the ends of the slates in the upper course.

*Straps* are thin pieces of iron running across the junction of two or more parts of a truss or frame of carpentry, branching out from the intersection in the direction of the several pieces, for the purpose of securing them to each other. They ought always to be double, *viz.* one strap on each side; and their ends strongly bolted to each of the pieces.

The uses of the various parts are illustrated as follows; and here it may be proper to observe, that though every one of the parts above defined may be found in the same roof, it is not necessary that a complete roof should have all these parts; the introduction of many of them depends on the distance of the walls, the contour of the roof, the partitions below, the quantity of head-room wanted in the garret-rooms, &c.

Of common roofs, the simplest construction is that which consists of two rafters, *AB* and *BC*, *Plate XLII. fig. 8*; *D* and *E* are wall-plates, on which the feet *A* and *C* of the rafters rest; the bottom of the rafters is cut in the form of a right angle (called by workmen a bird's mouth), reversed to the wall-plate, and is fixed to it with nails; but this form can only be applied to buildings that have their walls at no great distance from each other.

The next form is that of having two rafters, *AB*, *BC*, *Plate XLII. fig. 7*, a collar-beam *DE*, with two wall-plates, *F* and *G*, below. This form will admit of a greater distance between the walls than the other: the beam is placed in the situation *DE*, in order to give head-room within; but when the span, *FG*, of the walls is considerable, the parts *AD* and *CE* being considered as levers, and acted upon by the re-action of the walls, the rafters are either liable to be broken at the points *D* and *E*, or curved with a concavity on the upper edges.

The third form of common roofs consists of two rafters, *AB*, *BC*, *Plate XLII. fig. 10*, a tie-beam *AC*, for preventing the rafters from pushing out the walls, a collar or straining-beam *DE*, and two puncheons, or studs, *FG* and *HI*, for keeping the rafters straight: this construction is used for cheapness, and may be executed with safety in houses not exceeding forty-five feet wide; but it is necessary to have partitions immediately below, or at no great distance from the studs. Instead of supporting every opposite pair of rafters, as in this example, in many roofs of this construction, the rafters take the place of principals, and are fixed at 7, 8, 9, or 10 feet from each other, and purlins run over the heads of the puncheons at *K* and *L*; and at the ends of the collar-beams at *M* and *N*, between every two rafters, small rafters are fixed to the purlins, the wall-plates at bottom, and the ridge-tree at the top.

The most simple construction of a truss is that consisting of the following parts, *Plate XLII. fig. 9*. *AB* the tie-beam, cocked upon the wall-plates *C* and *D*; *EK* the king-post; *AG* and *BH* principal rafters, fixed to the king-post at the joggles, *G* and *H*; *LM* and *NO* struts, mortised into the rafters at *L* and *N*, and joggled to the king-post at *M* and *O*. Other names of timbers will be fully illustrated by the descriptions of other roofs in due order of succession. What has been said may suffice for the present.

## PROP. III.

The position of several rafters, *AB*, *BC*, *CD*, *DE*, &c. *Plate XLIII. fig. 1*, being given in a vertical plane, joined together and moveable about the angular points *B*, *C*, *D*, *E*, &c. while the points *A* and *G* remain stationary; it is required to find the proportion of the forces at the angles, so that the rafters may be kept in equilibrio.

Through the points *B*, *C*, *D*, *E*, &c. draw the vertical lines *Bi*, *Cm*, *Dp*, *Es*, &c. being the direction of the forces. Make *Bi* of any indefinite length, and complete the parallelogram *Bhik*. Make *Cl* equal to *Bk*, and complete the parallelogram *Clmn*. Proceed in this manner with all the remaining parallelograms, making the two opposite forces in the direction of each rafter equal to each other, and the diagonals, *Bi*, *Cm*, *Dp*, *Es*, &c. will represent the forces required, as is evident from the construction. Then, to find the proportion of the weights upon any two angles, the sine of any angle is the same with the sine of its supplement, therefore the sine of the angle *ABC* is the same as the sine of *Kbk*, or *Bki*; and the sine of *BCD* the same as the sine of *Cnm*; likewise the sine of the angle *Cml* is equal to the sine of the alternate angle *mCn*, and the sine of the angle *Dpo* is equal to the sine of the angle *pDq*; moreover, the sine of the angle *iBk* is equal to the sine of the angle *mCl*, and the sine of the angle *mCu* is equal to the sine of the angle *pDo*, and so on: then, because the sides of triangles are as the sines their opposite angles, it will be by trigonometry,

$$\begin{aligned} Bi : Bk, \text{ or } Cl :: S \cdot Bki, \text{ or } ABC : S \cdot Bih, \text{ or } iBh \\ Cl : lm, \text{ or } Do :: S \cdot Cml, \text{ or } mCn : S \cdot mCl, \text{ or } iBk \\ Do : op, \text{ or } Er :: S \cdot Dpo, \text{ or } pDq : S \cdot pDo, \text{ or } mCn \\ Er : sr, \text{ or } Fu :: S \cdot Esr, \text{ or } vFu : S \cdot sEr, \text{ or } pDq \\ Fu : Fv :: S \cdot Fvu, \text{ or } vFw : S \cdot vFw, \text{ or } EFG \end{aligned}$$

$$\text{Therefore } Bi : Fv :: S \cdot ABC \times S \cdot vFu \times S \cdot vFw \\ : S \cdot iBh \times S \cdot iBk \times S \cdot EFG$$

$$\text{Therefore } Bi : Fv :: \frac{S \cdot ABC}{S \cdot iBh \times S \cdot iBk} : \frac{S \cdot EFG}{S \cdot vFu \times S \cdot vFw}$$

That is, the weights on any two angles are as the sines of these angles directly, and reciprocally as the product of the sines of the two parts of these angles, divided by the vertical lines.

*Cor. 1.*—Hence the weights on any two angles are as the sines of the angles directly, and as the product of the cosines of the two parts of these angles reciprocally. For draw *BH* perpendicular to *Bi*, and produce *iB* and *AB* to *I* and *K*; then will the angle *KBI*, equal to the angle *iB*, be the cosine of the angle *HBK*; *viz.* the cosine of the angle of elevation of the rafter *AB* above the horizon; and because *CBI* is the supplement of *iBC*, the angles *CBI* and *CBi* have the same sine, and the angle *CBI* is the cosine of the angle *HBC*; *viz.* the angle of elevation of the rafter *BC*.

*Cor. 2.*—Hence also, the weights on any two angles are as the sines of the angles directly, and as the products of the secants of elevation jointly, because the secants of any two angles are reciprocally as the cosines of these angles.

*Cor. 3.*—The force which any rafter makes in its own direction is as the secant of its elevation. For make *AP* equal to *Bh*; draw the lines *PN*, *lH*, *nL*, &c. parallel to the vertical lines *Bi*, *Cm*, &c. and draw *AN*, *BH*, *CL*, &c. parallel to the horizon; then because the angles *NAP*, *HBl*, *LCn*, &c. are the angles of elevation, and *AN*, *BH*, *CL*, &c. are all equal, if *AN*, *BH*, *CL*, &c. be considered as radii, *AP*, *Bk*, *Cn*, &c. are the secants of elevation, which also represent the forces on the rafters.

*Cor. 4.*—Hence the horizontal pressures at *A* and *G* are equal;

# ROOF.

equal; for all the perpendiculars drawn from the opposite angles of each parallelogram to meet the vertical diagonal, are all equal.

*Cor. 5.*—Hence, if the position of any two rafters, and the proportion of the weights, be given, the position of the remaining rafters may be determined.

*Cor. 6.*—If the vertical line  $SDV$  be drawn, the horizontal line  $AVG$ , and the lines  $AS, AR, AQ, AT$ , &c. be drawn parallel to the rafters  $AB, BC, CD, DE$ , &c. meeting the vertical line in  $S, R, Q, T$ ; then will  $AS, AR, AQ, AT$ , represent the forces, and  $SR, RQ, QT$ , the forces upon the angles; for  $AS, AR, AQ, AT$ , &c. are the secants of the elevation, and the triangles  $ASR, ARQ, AQT$ , are all similar to the triangles  $bBi, lCm, oDp$ , &c.

*Cor. 7.*—In every roof kept in equilibrio by the weights of the rafters, if  $U, V, W$ , &c. be the centres of gravity of the rafters, and also represent their weights; then the weight pressing vertically on  $B$ , will be  $\frac{AU \times U}{AB} +$

$$\frac{VC \times V}{BC}, \text{ and the weight on } C = \frac{VB \times V}{BC} + \frac{WD \times W}{CD}$$

and so on; hence  $\frac{AU \times U}{AB} + \frac{VC \times V}{BC} : \frac{VB \times V}{BC} + \frac{WD \times W}{CD} :: S. bBi \times S. iBk : S. lCm \times S. mCn$ .

*Cor. 8.*—Hence, if the rafters be prismatic figures, the weights on the angles  $B, C, D$ , &c. will be respectively as  $\frac{AB}{2} + \frac{BC}{2}, \frac{BC}{2} + \frac{CD}{2}, \frac{CD}{2} + \frac{DE}{2}$ , and so on.

## PROP. IV.

Given the vertical angle of a roof, and the proportion of the rafters on each side, to describe the roof to a given width, so that it shall be in equilibrio.

Let the proportion of the rafters from the top downwards be as 2, 3, 4, that is, as 4, 6, 8; then the weight on the vertical angle is  $\frac{4+4}{2} = 4$ ; on the next succeeding angle  $\frac{4+6}{2} = 5$ ; and on the bottom angle  $\frac{6+8}{2} = 7$ .

(*Plate XLIII. fig. 2.*) Now let  $ABC$  be the given angle. Make  $BA$  equal to  $BC$ ; join  $AC$ , and draw  $DBE$  perpendicular to  $AC$ ; then make  $DB$  to represent half the weight of the vertical rafter: let  $BD$  be divided into two equal parts; make  $BM$  five of these parts, and  $ME$  seven; join  $MA, MC, EA, EC$ ; then from any scale of equal parts, make  $BF$  and  $BG$  each two parts; draw  $FH$  and  $GI$  parallel to  $MA$  and  $MC$ , and make  $FH$  and  $GI$  each equal to three equal parts of the same scale. Lastly, draw  $HK$  and  $IL$  parallel to  $EA$  and  $EC$ , and make  $HK, IL$ , each equal to four equal parts; then  $KH, HF, FB, BG, GI, IL$ , are the rafters, in the proportion required.

How to reduce this proportion of figure to a given width is obvious; it is only drawing a figure, having a given side in the same proportion as another.

## PROP. V.

The angular points at the meeting of every two rafters of a roof in equilibrio, by equal weights hung at the angles in vertical directions, equidistant from each other, are in the curve of a parabola.

Let  $ABCDE$ , &c. (*Plate XLIII. fig. 3.*) be kept

in equilibrio by equal weights, suspended at the angular points  $B, C, D, E$ , &c. in the equidistant directions  $BF, CG, DH, EI$ , &c. the points  $A, B, C, D, E$ , &c. are in the curve of a parabola.

For let  $BF$  meet  $AN$  at  $F$ . Draw  $AK$  parallel to  $DE$ ,  $AL$  parallel to  $CD$ , and  $AM$  parallel to  $BC$ , cutting  $FB$  at  $K, L, M$ . Draw  $BQ, CP, DO$ , parallel to  $AN$ , cutting the middle line  $IE$  at  $Q, P, O$ .

Then, because the weights on the angles are equal,  $FK, KL, LM, MB$ , are also equal, the first excepted, being half, or as the numbers 1, 2, 2, 2; therefore  $FK, FL, FM, FB$ , are as the odd numbers 1, 3, 5, 7; but because of the equidistant lines  $BF, CG, DH, EI$ , &c. and the parallels  $DO, CP, BQ, AI$ , the triangles  $AFK, AFL, AFM$ , are respectively equal and similar to the triangles  $DOE, CSD, BRC$ ; therefore  $KF$  is equal to  $EO, LF$  equal to  $DS$ , and  $DS$  equal to  $OP, MF$  equal to  $CR$ , and  $CR$  equal to  $PQ$ : and lastly,  $BF$  is equal to  $QI$ ; therefore  $EO, OP, PQ, QI$ , are to one another as the numbers 1, 3, 5, 7; and  $EO, EP, EQ, EI$ , are as the square numbers 1, 4, 9, 16; but the lines  $OD, PC, QB$ , are to one another as 1, 2, 3, 4; therefore the abscisses  $EO, EP, EQ, EI$ , are as the squares of the ordinates  $OD, PC, QB, IA$ , and the points  $A, B, C, D, E$ , are placed in the curve of a parabola. In the same manner it may be shewn, that this is the case, whatever be the number of ordinates.

*Corol.*—Hence a roof of this construction may be described to any given height and vertical angle, or to a given width and height, with any number of rafters on each side.

*Example.*—To describe a roof with any given number of rafters on each side to a given width and height, so that all the vertical lines passing through the angular points of the rafters shall be equidistant, and the rafters in equilibrio.

Let there be four rafters on each side, (*Plate XLIII. fig. 3.*) Let  $IN$  be half the width, and  $IE$  the height. Draw  $NT$  and  $ET$  parallel to  $IE$  and  $IN$ ; divide  $NT$  into four equal parts  $Nf, fe, ed, dT$ , and draw  $dgE, ehE, fiE$ ; likewise divide  $IN$  into four equal parts  $i, cb, ba, aN$ , and draw  $cg, bh, ai$ , parallel to  $IE$ . Join  $Eg, gb, bi, iN$ , and these lines will be the rafters of half the roof required.

For let  $CB$  (*Plate XLIII. fig. 4.*) be the height, and  $AB$  half the base. Draw  $CD$  parallel to  $AB$ , and  $AD$  parallel to  $BC$ . In  $AB$  take any point  $a$ , and divide  $AD$ , so that  $bd$  may be to  $AD$  as  $Ba$  to  $BA$ . Join  $bC$ , draw  $ac$  parallel to  $BC$ , meeting  $bC$  at  $c$ ; and  $cd$  and  $be$  parallel to  $AB$ , cutting  $BC$  at  $e$  and  $d$ , then the triangles  $Cdc$  and  $Ceb$  are similar.

Therefore  $Cd : Ce :: cd : eb$ , or  $AB$   
And by construction,  $Ce : CB :: aB$  or  $cd : AB$  or  $be$   
Therefore  $Cd : CB :: cd^2 : AB^2$   
Therefore the point  $C$  is in the curve of a parabola.

Another method may be as follows: Let  $BE$  (*Plate XLIII. fig. 4.*) be half the width,  $BC$  the height. Produce  $BC$  to  $F$ , making  $CF$  equal to  $CB$ . Divide  $CF$  into four equal parts,  $Cf, fg, gb, bF$ , and join  $fE, gE, hE$ . Divide  $BE$  into four equal parts,  $B, i, k, kl, lE$ , and draw the lines  $im, kn, lo$ , parallel to  $BC$ , cutting the former lines  $fE, gE, hE$ , at  $m, n, o$ ; the points  $m, n, o$ , are in the curve of a parabola. For the principles of this construction, the reader may consult Theorem VII. p. 123. vol. ii. Hut-ton's Mathematics.

## PROP. VI.

To describe a roof with four equal rafters, that shall be in

# ROOF.

in equilibrio by the weight of the rafters; of a given width A E, *Plate XLIII. fig. 5*, and height F C.

Join E C, and biseft it in H, by a perpendicular D H G, meeting A E in G; on G, as a centre, with the distance G E or G C, describe the circle C E O. Draw K H I parallel to F E, meeting the vertical line O C in K, and the circle in I. Draw I D C, and join D E; then make the side C B A similar to C D E, and A B, B C, C D, D E, will be the rafters of the roof required.

For complete the parallelogram C D Q B, and join B D, I F, and draw C L perpendicular to C F, and equal to F G. On L, with the distance G E, describe the circle N I F, meeting the vertical line at N and F; produce E D to meet it also in M, and B C to P.

Then becaufe K F is equal to K C, and R C equal to R Q, the triangles C I F and C D Q are similar; therefore I F is parallel to D Q: and becaufe the two segments N I F and C E O are equal to one another, the angle N I F is equal to the angle C E O, equal to twice the angle C E F, or twice the alternate angle E C L equal to E C D + D C L, but E C D is equal to half the external angle M D C, and D C L is half the angle D C P equal to C D Q. Therefore the angle N I F is equal to the angles M D C + C D Q equal to the angle M D Q, and C F : C N :: C Q : C M; but C F and C N are equal, therefore C Q and C M are equal; but C Q is to C M as the weight on C is to the weight on B; therefore the weights on C and B are equal, and the rafters A B, B C, C D, D E, are in equilibrio.

## PROP. VII.

Suppose it were required to construct a curb roof, the bottom rafter being in proportion to the upper rafter, as 2 to 3, and to a given vertical angle at the top, and to be of a given width A B, *Plate XLIII. fig. 6*.

Now the weight on the upper angle is to the weight on the lower angle, as  $\frac{2 \text{ H I}}{2}$  is to  $\frac{\text{H I} + \text{I A}}{2}$ , that is, as

$\frac{3 + 3}{2} = 3$  is to  $\frac{3 + 2}{2} = 2\frac{1}{2}$ ; this is in the proportion of 6 to 5, or the half weight at H is to the bottom weight at I, as 3 is to 5.

Biseft A B by the perpendicular C D, and make the angle A E C equal to half the vertical angle, or the angle E A C equal to its complement. Make E D to E C as 5 to 3. Join D A and D B. Take A G of any length; draw F G parallel to A E, and make A G to G F as 2 to 3. Draw A F H, meeting C D at H; and H I parallel to F G or E A, cutting A D at I; make B K equal to A I, and join K H; then A I H K B is the contour of the roof required. This is so evident from its construction, that it does not require demonstration.

## PROP. VIII.

In any roof constructed with two equal rafters only; as the height of the roof is to half the breadth of the building, so is half the weight of the roof to the horizontal thrust, or lateral pressure.

Let A B C, *Plate XLIV. fig. 1*, be a roof, having the two equal rafters A B, B C; join the bottom of the rafters A C; draw B D perpendicular to it; complete the parallelogram B E F G, and draw E G, cutting B D in H. Then, becaufe the triangles B H E and B D A are similar, B D : D A :: B H : H E.

*Cor. 1.*—Hence, in a roof with two rafters and a tie-

beam at the bottom, the tension, H E, of the tie-beam is

$$= \frac{D A \times B H}{B D}.$$

*Cor. 2.*—Hence, also, B D : B A :: B H : B E, that is, as the height of the roof is to the length of the rafter, so is half the weight, represented by B H, of the roof to

the compression of the rafters =  $\frac{B A \times B H}{B D}$ .

*Cor. 3.*—Half the weight of the roof, the tension of the tie-beam, and the compression of the rafters, are to one another as the height of the roof, half the breadth of the span, and the length of the rafters; for the triangle B H E is similar to the triangle B D A.

## PROP. IX.

If a rafter bear any weight, or have a weight uniformly diffused over it, the force tending to break it is equal to the cosine of elevation, multiplied into the weight, divided by radius.

Let A B, B C, *fig. 2*, be two equal rafters; join A C, draw B G perpendicular to it, meeting it in G; and let the weight W be suspended by the string D E. Draw D F perpendicular to A B, and E F parallel to it; then if D E represent the weight, D F will represent the force tending to break the rafter; F E its tendency to push it from B towards A.

Now, becaufe E F is parallel to A B, the alternate angles A D E and D E F are equal, and the angles D F E and A G B are right angles; the triangles E D F and B A G are similar; therefore A B : A G :: D E : D F

=  $\frac{A G \times D E}{A B}$ , that is, as radius is to the cosine of elevation, so is the force employed to its tendency to break the rafter, that is, as R : cof. :: D E : D F =  $\frac{\text{cof. elevation} \times D E}{R}$ .

*Cor. 1.*—Hence the weight employed, the pressure in a direction of the length of the rafter at A, the tendency to break it, are as radius, the sine, and cosine of elevation.

*Cor. 2.*—Becaufe D F =  $\frac{\text{cof. elevation} \times D E}{R}$ , and be-

caufe the streffs is as the length when the weight is given, the streffs is as the cosine of elevation multiplied into the weight, and this product multiplied into the length of the rafter, the radius being a constant quantity.

## PROP. X.

To prevent the rafters of a roof, with a tie-beam, from bending in the middle, and to remove lateral pressure from the walls, when there is no beam.

A variety of methods may be used for this purpose; but the best are those where the shortest and least quantity of timber are employed without producing a transverse strain upon any part. When a roof consists of two rafters only, no part of the rafters can be loaded between their extremities, nor indeed will they bear their own weight without producing a concavity on the upper side, which will be greater as the length of the rafter and weight applied to it are greater. Now becaufe the shorter the rafters are at the same elevation, the greater the weight they will bear, and be more able to support their own weight; the thing to be done is to support them by a sufficient number of fixed

## ROOF.

points either from the roof itself, or other immoveable places. There are three points for this purpose; if the rafters have a tie-beam below, that is, at the vertex, and at the two extremities of the rafters, the triangle being immoveable at the angles, every force applied there tends either to compress or extend the sides of the frame without transverse strain.

*Examples.*—Let it be required to divide each of the rafters into three equal lengths, in order to support two purlins on each side; this may be done, as in *fig. 3*, by pieces, C E, C D, A G, A F, reaching from the two lower angles C and A, and to the opposite sides of the rafters A B and B C, intersecting each other at H and I, and halved upon each other at these interfections: this mode prevents the rafters from sagging, but does not afford any support to the tie-beam. The meeting of so many braces at the same point, too, gives little opportunity of making the ends entirely secure, even though assisted by iron straps. Another mode may be by introducing a king-post, B K, *fig. 4*, to which the struts D H, E I, F M, G L, may be firmly joggled at H, I, M, L, and mortised to the rafter at D, E, F, G: this method keeps up the middle of the beam, but when the roof is low, and the span great, the struts, D H and F M, require themselves to be supported, and are much too oblique to prevent a change of figure.

Another method may be as in *fig. 5*, with the king-post in the middle, as before, two queen-posts under the rafters at E and F, two struts, H E and I F, joggled to the bottom of the king-post at H and I, and to the top of the queen-posts at E and F; and in order to secure the points N and P, two other braces, N Q, P R, are joggled to the bottom of the queen-posts at Q and R, and mortised into the rafters at the upper end. This construction supports the tie-beam in three different points, and each of the rafters in two. The timbers are much shorter than those of the preceding; but so many joggles are certainly an objection to this method, as the shrinking of the timber must be very considerable in three breadths, which would allow the roof to descend. When the span is great, and the points to be supported many, an excellent method may be as in *fig. 6*, where there are two arches of cast-iron or good English oak introduced, which abutt on the king-post, and at the other extremity at the ends of the beam. The rafters and the beam by this mode may be supported by as many equidistant points as we please.

When the tie-beam is removed from the bottom, as in *fig. 7*, and no fixed points are to be found from below, a longitudinal truss may be constructed, the end of which is shewn at A B, and the manner of framing it in *fig. 9*, the two ends being supposed to be firmly fixed into the gables; but where the length is great, the form of *fig. 10*, with a parabolic arch, would be much better: by this method, the rafters will be kept nearly in the same plane, and all lateral pressure from the walls will be removed; for it is evident that if the ridge-tree is supported, there can be no motion downwards in the direction of the rafters, the whole roof being hung to this longitudinal frame.

### PROP. XI.

If a roof be constructed with two equal rafters, A M, C M, (*fig. 8.*) and if a tie extend from the bottom of each rafter to an intermediate point in the opposite rafter, and the ties halved together at their intersection B, forming with the rafters a quadrilateral M D B E at the vertex, and two triangles A D B and C E B; then if M D is equal to M E, and if C P represent the direction and quantity of force

on the wall at C, the force tending to break the rafters at

$$D \text{ and } E \text{ is } \frac{S. PCK \times S. DME \times LK \times DM}{S. LCK \times R}.$$

For complete the parallelogram P C L K; make M N equal to C L, and draw N O parallel, and M O perpendicular to A M. Now the triangles C B E and A B D may be looked upon as solid levers, (at least with regard to forces applied to the angles,) moveable round B. Then the force C P will communicate the force C L to the rafter, and C L is the power acting obliquely at M, upon the rafter A M: then because N O is parallel, and O M perpendicular to A M, O M is the force tending to break the rafter at D; O N that pushing it towards A: let M N be considered radius, then O M will be the sine of the angle D M N, or D M E; for produce A M to Q, and the angle N M Q will be the supplement of the vertical angle D M E, therefore the sine of N M Q, equal to the sine of the angle M N O, is the same with the sine of N M A; then by trigonometry,

$$\begin{aligned} LK : LC :: S. LCK : S. CKL \text{ or } S. PCK \\ NM \text{ or } LC : MO :: R : S. DME = S. MNO \\ \text{Therefore } LK : MO :: S. LCK \times R : S. PCK \times \\ S. DME. \end{aligned}$$

$$\text{Hence } MO = \frac{S. PCK \times S. DME \times LK}{S. LCK \times R} = \text{the}$$

force acting perpendicular to A M at M, but the force tending to break the rafter at D, is as the lever D M multiplied

$$\text{into this force; that is } = \frac{S. PCK \times S. DME \times LK \times DM}{S. LCK \times R}.$$

*Corol. 1.*—Hence, if the angle D M E is a right angle, the force tending to break the rafter at D will be  $\frac{S. PCK \times LK \times DM}{S. LCK}$ .

*Corol. 2.*—Hence the rafters of every roof of this construction must sag in a greater or less degree, by the action of the rafters against each other at the point M, that is, they will be bent into curves concave on the upper edges; but if a diagonal connect the two vertical points M and B, this change of figure will be prevented.

### PROP. XII.

To remove the lateral pressure of a roof without any intermediate beam, brace, or strut.

Let A B, B C, (*Plate XLV. fig. 1. N<sup>o</sup> 2.*) be two rafters, and let there be constructed a strong wall-plate D E F G, N<sup>o</sup> 1, firmly bolted together at the angles; then if the roof is to be gable-ended, after having fixed the rafters to a common ridge-tree, let two curves be made of cast-iron, or good English oak, of a parabolic form, and let into the rafters, either on the upper or under surface, and firmly secured to them by bolts or nails, and at their lower extremities to the angles of the wall-plates, the vertex of each curve meeting the ridge-piece on each side of it, or nearly, as may be found convenient. One half of the plan N<sup>o</sup> 1. exhibits the form for the execution of a gable-ended roof, and the other for a hiped roof. The two sides, laid in plano for each form, are shewn in N<sup>o</sup> 3 and 4; at H I K L and M N O P, H L and D G represent the same wall-plate; D G, N O, and E F another wall-plate, I K and M P meeting the ridge on each side of it: but it must be observed, when the roof is to be hipt, that the ridge-tree must be very strong, as the compressure will be very great, the hip-rafter acting like powerful braces at the extremities of it. Hence it is evident that the wall-plates act as the tie-beams

## ROOF.

beams of a common roof, and the curves as the rafters, or more naturally like an arch of a bridge in equilibrium. It has already been shewn that equal weights, acting in equidistant lines, require an arch of a parabolic form to keep them in equilibrio. In this it is to be considered, that as the arches are placed with their crown upwards, they are in a state of compression, and may be got out very conveniently in several lengths; but if the arches were inverted they would be in a state of tension: each arch must then be in one piece; the ridge would be compressed by the tension of the two curves. This inverted disposition of equilibration is not so secure as when the crown of the arches either meets the ridge or lies towards it. Though the above construction will prevent lateral pressure, it will not hinder the rafters from sagging; but the addition of a collar-beam will effectually answer this purpose in all moderate spans.

### PROP. XIII.

Given the construction of a roof, of which not more than three timbers meet at the same junction, and a force in the direction of any one of the timbers; to find the forces communicated to the other timbers, so that the roof shall be in equilibrio.

Begin with the given force, and take a part of the line of its direction from the junction to represent it; then with the other two directions complete a parallelogram, and apply them from the next junctions on the same straight line from which they were taken, and complete parallelograms as before. Proceed in this manner from one junction to another, until parallelograms have been made at every junction. Then the parts of these parallelograms in the directions of the timbers are the forces in these directions; then to know the state of tension or compression of any timber, observe that when two of the angles formed by three directions are less than two right angles, the middle force acts always contrary to the two extreme ones, as has already been explained; and that when any two of the angles of direction are greater than two right angles, then the forces will act towards or from the same point.

*Example 1.*—Let  $ABCDA$  (*fig. 2.*) be a roof, consisting of two rafters,  $AB, BC$ , two beams,  $CD, DA$ , and a king-post,  $DB$ , supported by the walls  $AO$  and  $CE$ . Let  $CE$  represent half the weight of the roof, or the re-action of the wall  $CE$ ; complete the parallelogram  $CEFG$ ; make  $DL$  equal to  $FC$ , and complete the parallelogram  $LMND$ , then  $CF$  or  $DL$  is the force in the direction of the beam  $CD$  or  $AD$ , and  $DM$  the force in the direction of the post  $DB$ ; then because the angles  $ECF$  and  $FCG$  are less than two right angles, and because the point  $C$  is pressed by the re-action of the wall  $EC$ , it will also be pressed by the force  $GC$ , and drawn by the force  $CF$ ; therefore the beam  $CD$  is in a state of tension, and the rafter  $BC$  in a state of compression. Again, because  $CD$  and  $BD$  are greater than the two right angles, and because  $CD$  is in a state of tension,  $BD$  and  $DA$  are also in a state of tension.

If  $BH$  be made equal to  $GC$ , and the parallelogram  $BHIK$  completed, and if  $BP$  be made equal to  $DM$ , then will  $PI$  be equal to twice  $CE$ , the pressure on the walls.

*Example 2.*—Let  $ABCDEA$  (*fig. 3.*) be a roof supported by walls in the direction  $PA$  and  $QC$ , and let there be two pieces of timber,  $BD$  and  $BE$ , connecting the angular points  $D$  and  $E$  to the ridge at  $B$ .

Take  $CF$  to represent half the weight of the roof, or the re-action of the wall  $QC$ : complete the parallelogram

$CFGH$ , produce  $CD$  to  $K$ , make  $DK$  equal to  $GC$ , and complete the parallelogram  $DIKL$ ; then  $GC$  or  $DK$  is the force in the direction of the timber  $CD$  or  $AE$ , and is in a state of tension, because the angles  $FCG$  and  $GCH$  are less than two right angles, and because  $CF$  is in a state of compression;  $CH$ , the force in a direction of the rafter  $BC$ , is also in a state of compression; and because any two of the three angles  $GDB, GDE, EDB$ , are greater than two right angles, and  $DC$  is in a state of tension, the two pieces,  $DB$  and  $DE$ , are also in a state of tension: that is,  $EA, EB, ED, DB, DC$ , are all ties. The force in  $DB$  or  $EB$  is  $DL$ , that in  $DE$  is  $DI$ .

If  $BR$  and  $BS$  be made equal to  $CH$ , and the parallelogram  $BRWS$  completed; and if  $BT$  and  $BU$  be made equal to  $LD$ , and the parallelogram  $BTUV$  completed, then will  $VW$  be equal to twice  $CF$ , that is, by reducing the force in the direction of the pieces  $BE$  and  $BD$  to an equivalent one.

### PROP. XIV.

Given the lengths  $AB, BC, CD, DE$ , (*Plate XLVI. fig. 1.*) of the rafters of a roof and their angles of position, to find those angles that require ties, and those which require struts.

Let  $AB$  be to  $BC$  as 3 is to 4, that is, as 6 to 8, the proportion of the weight of the rafters; then if 8 be taken for the weight of each of the upper rafters,

$$\frac{8 + 8}{2} = 8$$

is the weight on the vertical angle  $C$ , and  $\frac{6 + 8}{2} = 7$ , will

be the weight on each of the vertical angles  $B$  and  $D$ , so that the weight on the vertical angle is to the weight on each of the lower angles, as 8 is to 7. Draw the vertical line  $BGF$ , and draw  $AG, AF$ , parallel to the rafters  $BC, CD$ ; then if  $FG$  be to  $GB$  as 8 to 7, the rafters are in equilibrio, and require no ties. But suppose it should be found that  $FG$  is to  $GB$  as 1 to 2; now as that will keep it in equilibrio, it would then require a very considerable addition laid on the angle  $B$  to keep it from springing outwards, so that if two braces,  $FG$  and  $KL$ ,  $N^o 2$ , were fixed to the rafters  $AB, BC, CD, DE$ , these braces would be in a state of compression, and if the brace  $HI$  were fixed at the top it would be in a state of tension:  $FG$  and  $KL$  only require firm buttments, but  $HI$  to be well bolted. It may here be observed, that if the vertical angle only be braced and secured to the two rafters, the whole frame will then be immoveable.

### PROP. XV.

To discover the effect of bracing the angles of a roof flat on the top, supported by puncheons at the bottom of the rafters, to accommodate a semicircular ceiling within.

Let  $ABCDEF$  (*fig. 2. N<sup>o</sup> 1.*) be the trufs, divided of its braces, the bottoms of the puncheons resting firmly on the walls at  $A$  and  $F$ , and the joints at  $B, C, D, E$ , to be quite moveable, like rule joints. Now, as this disposition of timbers would fall, and in falling, would assume the form of  $N^o 2$ , the angles at  $C$  and  $D$  would become more and more obtuse, while those at  $B$  and  $E$  would become more and more acute; the latter would therefore require straining-pieces, and the former ties: the straining-pieces must have good abutments, and the ties be well bolted at their extremities.

Let  $N^o 3$  be the trufs, with braces disposed in the lower angles: this disposition will bend the rafters  $BC, DE$ , and the puncheons  $BA, EF$ , convex towards the outside, which

## ROOF.

is entirely occasioned by the braces G H and N O: the camber-beam C D is no otherwise affected than by its own weight. Let it now be supposed, that the angles C and D, N<sup>o</sup> 4, are braced at I K, L M. In this disposition, the puncheons B A and E F are not affected in respect of transverse strains; the rafters C B, D E, and beam C D, would all become concave on the outside; and the points B and E, at the bottom of the rafters and top of the puncheons, would be pushed out beyond the perpendicular of A and F, at the bottom: here it is necessary to observe, that the effect produced in this case on the rafters C B and D E is contrary to the effect produced in N<sup>o</sup> 3, by the braces being disposed in the lower angles. Lastly, suppose that all the angles are braced, as in N<sup>o</sup> 5, it is evident, since the braces H G, N O, produce a contrary effect to the braces K I, L M, these bending the rafters downwards, and those upwards, that the rafters C B and D E will become nearly straight, or assume an undulated line: the puncheons B A and E F, receiving the force of the braces H G and N O at the points G and O, must still be bent, so long as the under ends G and O of the braces do not coincide with the under ends A and F of the puncheons: in this case, there is no other remedy than by giving the puncheons a scantling sufficient to withstand this transverse strain, or horizontal thrust, at the points G and O: however, the shape of the contour may be pretty well secured by introducing two abutments, H I and M N, N<sup>o</sup> 6; these, by being bolted through the two ends, will add greatly to the stiffness of the rafters B C and D E: the bolts that go through the upper ends may also serve for the braces I K and L M: the shape of the horizontal beam C D will likewise be very much preserved by the piece K L, bolted in three places, one at each end, into the braces I K and L M, and another in the middle: the contour of a roof, thus supported, would be quite unchangeable, if the rafters were inflexible; but as this is not the case, and as they are acted upon transversely by the braces, the truss will, therefore, in some degree, be expanded at B and E, and consequently occasion lateral pressure on the walls; it will therefore be unfit for an oblong building, without other precautions for this purpose. By inserting parabolic curves in the sides B C and D E, as in *Plate XLVI. fig. 1*, it will be effectually prevented.

In roofs of this description, joggle-pieces of wood should never be used, as the shrinking of them would tend greatly to alter the outline of the rafters.

Having laid down such principles as will enable the workman to judge of the strength and strain of timbers in the framings of carpentry, it will now be necessary to proceed to shew the mode of constructing roofs to answer various purposes; to give some practical observations relative to their strength, and to shew the various modes of joining timbers, the forms of straps, &c.

*Plate XLVII. fig. 1.* is the roof of the chapel of the royal hospital at Greenwich, constructed by Mr. S. Wyatt.

	Inches Scantling.
A A, The tie-beam, 57 feet long, the span of the walls being 51 feet	14 × 12
B, Queen-pofts - - - - -	9 × 12
C, Braces - - - - -	9 × 7
D, Straining-beam - - - - -	10 × 7
E, Straining-piece - - - - -	6 × 7
F, Principal rafters - - - - -	10 × 7
G, Camber-beam for the platform - - - - -	9 × 7
H, An iron rod, supporting tie-beam - - - - -	2 × 2

The trusses are seven feet clear; the platform is covered

with lead, which is supported by horizontal beams six by four inches.

The timbers of this truss are well disposed, and perhaps contain less wood than most roofs of the same dimensions. The iron rod seems of no other utility than to prevent the middle compartment of the beam from sagging.

*Fig. 2.* is the roof of St. Paul's, Covent-Garden, designed by Mr. Hardwick, and constructed by Mr. Wapshot, in 1796.

	Inches Scantling.
A A, The tie-beam, spanning 50 feet 2 inches	16 × 12
B, Queen-pofts - - - - -	9 × 8
C, Straining-beam - - - - -	10 × 8
D, King-poft, 14 inches at the joggle - - - - -	9 × 8
E, Strutts - - - - -	9 × 8
F, F, Auxiliary rafters, at bottom - - - - -	10 × 8½
H, H, Principal rafters, at bottom - - - - -	10 × 8½
I, Studs supporting the principals - - - - -	8 × 8

This roof is much better constructed than the original one by Inigo Jones. A truss of the present design contains only 98 cubic feet of timber, whereas that by Inigo Jones had 273, and was very insufficient at the joggles, and had some of its timbers very ill disposed: the interior truss is well contrived for supporting the exterior, which reaches seven feet beyond the walls. The tie-beam has perhaps too much camber, being six inches; for since it acts as a string, it will lengthen in the settling of the roof.

*Fig. 3.* is the roof of Drury-lane theatre, 80 feet 3 inches span, and the trusses 15 feet apart: constructed by Mr. Edward Gray Saunders.

	Inches Scantling.
A, Beams - - - - -	10 × 7
B, B, Rafters - - - - -	7 × 7
C, King-pofts - - - - -	12 × 7
D, Strutts - - - - -	5 × 7
E, Purlins - - - - -	9 × 5
G, Pole-plates - - - - -	5 × 5
H, Common rafters - - - - -	5 × 4
I, Tie-beam - - - - -	15 × 12
K, Pofts to ditto - - - - -	15 × 12
L, Principal braces to ditto - - - - -	14 and 12 × 12
M, Strutts - - - - -	8 × 12
N, Straining-beam - - - - -	12 × 12

The principal beams are trussed in the middle space with oak braces, five inches square. This was requisite on account of its width, which is thirty-two feet, that the floors might carry the work-shops necessary for the use of the theatre. This truss is most admirably constructed, it is hardly equalled for strength, stiffness, and lightness by any other, and will safely bear a load of nearly 300 tons, which is four times more than ever it is likely to be loaded with.

*Plate LVIII. fig. 1.* is the design of a truss-roof for a church, with a nave and two side aisles. The beam of the middle compartment is kept from sagging in the middle by two strutts, resting at the bottom on pofts over the columns, and connected together at the top by a straining-piece. As the pofts firmly support the middle of the rafters, keeping these points always stationary, there will be little danger of lateral pressure from a roof of this construction. All that is wanted further is to give the rafters stiffness, by fixing other pieces from the two fixed points of the tie-beam, and from the two pofts.

*Fig. 2.* is a design for the truss of a curb-roof, with a door in the middle. The rafters are supported at equal distances, from

## ROOF.

from fixed points of the trufs; the weight of the covering being always uniform, or nearly fo.

*Fig. 3, N° 1*, a design for a roof, with lanterns in feveral ftages, diminishing in the form of fome Chinefe buildings. Thefe towers may be carried to any height, at pleafure, by always truffing in the plane of the diagonal between every two ftages from the lower, to fupport that immediately above. There are fome excellent fpecimens to be feen in the buildings of Deptford, belonging to the victualling office, called ufually the Red-houfe. *N° 2*, is a plan for the feat of the upper ftage

*Fig. 4*, is the design of a conic roof for a rotunda or circular building, fupporting a lantern at the top. If the extent of the building is very large, the rafters would require to be fupported in the middle; for this purpofe the bottom piece may be continued, as is expreffed by the dotted lines.

*Fig. 5*, is a design for a pent roof, fupporting a lantern on an octagonal form. *N° 1*, is the form of the trufs; *N° 2*, the lower plan, with the feat of the pots; *N° 3*, the plan of the upper part; *N° 4*, the trufs of the two tranfverfe parts.

Having defcribed the form of roofs fupporting lanterns, and the trusses in which they may be executed with fafety, it will now be proper to give a few examples of domes, and fhew how they may be conftituted under various circumftances. If the dome to be conftituted be on a circular plan, and have no lantern above, the ribs may be built in the following manner, with planks of convenient lengths in three thickneffes. Having afcertained the length of the ribs, and the number of pieces in that length, and having properly fhaped all the pieces to the curve, the middle piece at the bottom may be one of thefe lengths; to each fide may be joined two other pieces, one reaching to a third of the middle piece, and the other to two-thirds from the bottom; fo that by continuing with planks of the whole length to the other extremity of the rib, the middle thicknefs will always be covered two-thirds from the bottom on one fide, and one-third on the other; the deficiency at the top muft be filled up with pieces, one of a third and the other of two-thirds, as at the bottom; the whole, being well bolted together and strapped acrofs the joints, will be nearly as ftrong as a folid rib. *Plate LIX. fig. 1* fhews the manner of conftituting this kind of dome; *N° 1* being the femi-plan, *N° 2* the elevation, *N° 3* the manner of building the rib. In domes of this kind it may fometimes be neceffary to difcontinue the ribs, in order to divide the fpaces more equally for the horizontal ribs. It is evident that a dome built in this manner may be carried almoft to any degree of extent, provided that it have a fufficient number of horizontal ribs. Of this conftitucion is the Halle du Bled at Paris, of 200 feet in diameter, the invention of a judicious carpenter, the Sieur Molineau, a man of little education in the point of fciences, but of confiderable mechanical experience, from which he formed his theory. Being convinced that a very thin fhell of timber might not only be fo fhaped as to be nearly in equilibrio, but that, if well connected with horizontal ribs, it would have all the ftiffnefs that was neceffary; he accordingly prefented his fcheme to the magiftracy of Paris: the grandeur of the idea pleafed them, but they doubted of the poffibility of its being put in practice. Being a great public work, they prevailed on the Academy of Sciences to confider it. The members, who were competent judges, were ftrock with the juftnefs of Mr. Molineau's principles, and aftonifhed that a thing fo plain had not become familiar to every houfe-carpenter. It quickly became an univerfal topic of converfation, difpute, and cabal in the polite circles

of Paris. But the Academy having given a favourable report of their opinion, the project was immediately carried into execution and foon completed, and now ftands as one of the greateft exhibitions of Paris. The circular ribs which compofe this dome confift of planks 9 feet long, 13 inches broad, and 3 inches thick, made in three thickneffes, as in that already defcribed. At various diftances thefe ribs were connected horizontally by purlins and iron straps, which made fo many hoops to the whole. When the work had reached fuch a height, that the diftance of the ribs was two-thirds of the original diftance, every fecond (now confifting of two ribs, very near each other,) was in like manner difcontinued, and the void glazed. A little above this the heads of the ribs are framed into a circular ring of timber, which forms a wide opening in the middle, over which is a glazed canopy or umbrella, with an opening between it and the dome, for allowing the heated air to get out. All who have feen this dome fay, that it is the moft beautiful and magnificent object they ever beheld.

The only difficulty which occurs in the conftitucion of wooden domes, is when they are loaded in the upper part by a heavy lantern or cupola. Such a dome as has now been defcribed would be in danger of being crufted at the top inwards; the moft effectual method of preventing which is by making the ribs in the form of trusses, as in *Plate LIX. fig. 2*, where the ftraight pieces connecting the two extremities of the exterior fide, forming as it were the bafe of a trufs in a common roof, act contrary to the nature of a tie-beam; they refift the vertical preffure of the lantern, without having any tendency to burft out the fides, by acting entirely longitudinally on the wall-plate. In order to fecure the lantern, horizontal braces are fixed from the bottom of the lantern to the middle of the principal braces under the joggles, fo that the whole is refolved into triangles, which are all immoveable at the angles. The wall-plates fhould be framed as the ribs of a dome, conftituted as in the laft example.

When a dome is to fupport a heavy cupola of ftone, fuch a conftitucion as that of the cathedral of St. Paul's, London, may be employed. *Fig. 3. N° 1*, exhibits the trufs of this dome, taken from accurate meafurement. *A a a A*, a dome of brick, two bricks thick, which, as it rifes every five feet, has a courfe of ftrong bricks 18 inches long, bonding through the whole thicknefs. *B b b B* is a cone, built with bricks one foot fix inches in thicknefs, for fupporting the heavy cupola above, of Portland ftone, which is 21 feet diameter, and near 61 feet high, and alfo the timber-work of the dome. The horizontal or hammer-beams, *C, C*, &c. being curioufly tied to the corbels *D, D, D*, &c. with iron cramps, which are bedded into the corbels with lead, and bolted to the hammer-beams. *N° 2*, fhews more particularly the manner of tying the hammer-beams to the corbels.

This dome is boarded from the bafe upwards, and the ribs are therefore fixed horizontally, having their fides in planes tending to the centre of the dome. The contour of the dome is formed of two circular fegments, which meet in the axis like a pointed arch. The feantlings of the curve rib of the trufs are 10 inches by 11½ at the bottom, and 6 inches by 6 at top. It has a very ftrong double iron chain, linked together at the bottom of the cone, and feveral other lefs ones between that and the cupola, which may be feen in that beautiful fection of St. Paul's, engraved by Rooker. This dome was turned upon a centre, which was fupported without any ftandards from below. As every ftory of the feantling was circular, and the ends of the ledgers meeting like fo many rings, and truly wrought, it fupported itfelf; and as it was both centering and feaffolding it remained for the

## ROOF.

the use of the painter, there being a space of twelve feet between it and the dome. This machine, it is said, was original of its kind.

Roof, *Rotative*, or *Rotatory*, in *Astronomy*, is one which is made to turn round in a horizontal direction, so that its openings or doors may be directed to any azimuthal line in the concave expanse of the heavenly regions. In a transit room, where a meridian line is the only one that is wanted, a fixed roof, with trap-doors opening at different altitudes above one another, sufficiently answers the purpose of the astronomer; but in an observatory, where an instrument that measures azimuths as well as altitudes is placed; or where a good telescope, of either the achromatic refracting, or reflecting construction, is used, for viewing the stars and planets in various parts of the heavens on the same evening, a rotative roof is indispensably requisite. The construction which has been most generally adopted, and which we shall first describe, was contrived by the ingenious Mr. Smeaton, one of whose papers, of the date of 1788, now lying before us, was designed for the late Mr. Aubert's observatory at Highbury, and will supply us with materials sufficient for the purpose of illustration. In *Plate XXII. of Astronomical Instruments*, *fig. 1.* represents a section of the whole roof along that plane, which passes through the doors, or opening, that divides it into two equal portions; *fig. 2.* is the plan of the same, and serves to illustrate *fig. 1*; in both these, *a, a,* are the rafters, or door-cheeks, covered by two oblong doors meeting at the apex, and so contrived by close fitting, as to exclude the rain and snow when nicely made. An enlarged section across one of these doors is seen in *fig. 3.* and will be explained presently. The frame of the roof is covered with alternate boards of deal of a triangular shape, tongued into one another at the edges, and when perfectly put together with strong glue, and several times painted over, will be light, and will last several years; but if a coat of copper, particularly of tinned copper of Mr. Wyatt's patent manufactory, be superadded, the weight will not be considerable, and the durability will be ensured. A square foot of Mr. Wyatt's copper of the thinnest kind weighs a pound, and therefore a given number of square feet will be covered by so many pounds weight. An edge plate, formed into a circle, terminates the eaves, and conceals a strong annular support, which rests on ten rollers, five of which are seen in *fig. 1.* three as circles, and two at the extremities of the roof in section as small parallelograms. All the ten rollers are represented in the ring seen in *fig. 4.* which is united by five pairs of hinges that connect the five equal portions thereof, as seen on the plane of the ring; while each of these five portions contain two rollers seen in section, and one handle projecting inwards. The use of the hinges is to allow each of the five portions of the ring to yield to the pressure of the superincumbent roof, in order that all the rollers may be made to act in every position of the roof, in the event of any of the parts becoming distorted or partially worn. This ring, which receives the pivots of the rollers, lies intermediate between the roof and fixed circle that bears the whole weight, and is represented by the letters *b, b,* in *fig. 1.* the fixed circle or bed being denoted by the letters *c, c;* both which, in the section, appear as straight lines, though they are circles or rings, as above described, and the fixed one, *c c,* rests on strong upright pieces, *d, d,* properly braced by frame-work, which it is not necessary to shew. From this short description the reader will now conceive that the roof is separated from the bed *c c,* by exactly the whole diameter of the rollers, which therefore ought to be turned nicely to the same dimensions, in order to preserve the horizontal position of the ring, and to make the rollers

act smoothly, when the roof is pushed round by any force internally applied; but unless some provision is made, more than we have yet described, the roof might be pushed from its bed, and be upset; to avoid this accident a groove is made along the upper face of the annular bed *cc,* in which the rollers move, and while all the parts of this contrivance remain unaltered by the weather, the action of the rollers is uniform, and the construction answers its purpose in a satisfactory manner: but in many instances, we learn that the work of turning a large roof, thus constructed, becomes laborious, in consequence of either the ring of rollers, or the groove in the bed, taking an elliptical shape, in a small degree, by partial shrinking or swelling in different states of the atmosphere; in which case the rollers bind in the groove, and require mechanical force to move them, in certain parts of the revolution; which force will of course strain the joints, and ultimately destroy the union of the different parts of the structure. It is, therefore, of importance that an attention be paid to the grain of the wood, as well as to its being seasoned, before the upper covering be attached; which precaution will prevent the bad effect of external moisture. At *c,* in *fig. 3.* is one of the hinges of the doors, attached first to the side of the door, and then to a piece of wood that lies over the roof to receive the screws, without penetrating the roof itself; and the crank-shape of the section of the door will explain how it clasps the door-cheeks, so as to exclude the admission of rain or snow, so long as the materials do not warp or decay. The handle-piece, *f,* pushes the door back, and brings it close again, by the aid of a staff with a hook at the end, that takes hold of the ring at the lower extremity of the handle *f,* when the roof is too far elevated for the reach of the human hand. During the perusal of this account of the mechanism of Smeaton's rotatory roof, it may have occurred to the reader, that the rollers might have been attached to the annular portion of the roof, which now rests on the upper extremities of the rollers, and that consequently the ring, that now carries the said rollers, and that is represented by *fig. 4.* might have been omitted. But the inventor had a good practical reason for the introduction of this ring, which may not yet have occurred to our reader; and it might perhaps puzzle him to discover it, without our assistance. Smeaton knew very well that the roof with rollers, or small wheels under it, would move in a groove made in the bed to receive them; but he knew, moreover, that, to move in a circular groove, the diameters of the rollers could not be great, without sticking fast against the sides of the said groove; and, also, that the pivots of the rollers must be strong, to support the whole roof. The relative diameters of the rollers, and of their pivots, on which the quantity of friction depends, would not consequently produce, under these circumstances, the easy motion of the roof that constitutes a leading object of the astronomer: the ring was, therefore, introduced, for the purpose of diminishing the friction *one-half,* without altering the necessary dimensions of the rollers, and of their pivots; which effect may be thus explained. In the first place, supposing the roof to be moving forwards on rollers attached to it, like a carriage on wheels; in this case, the velocity of the roof and of the rollers, or of the carriage and wheels, would be the same; and the horizontal distance passed over in a given number of revolutions of the roller, or wheels, would be measured by the circumference of the roller, or wheel, multiplied by its number of revolutions; and the mechanical diminution of friction would be as the diameter of the roller to that of the pivot of the axis, or of the wheel to that of its axle. When a motion is thus produced in a roof, or in a carriage,

## ROOF.

a carriage, we may say that it *rides* on, or is *carried* by its roller, or wheel, and that with the same velocity with which the roller or wheel moves forwards, by virtue of its rotations. But, in the next place, let the rollers be considered as attached to the ring in *fig. 4*, which has as many holes cut through it as there are rollers for them to pass through; and let us conceive this ring to be put in motion, as it is placed on its circular bed *cc*, without any reference to the roof. In this situation, the ring rides on, or is carried by the rollers with their velocity, as the roof or carriage was on our first supposition. Let now the roof rest on wedges placed on the ring, but so as *not to touch* the rollers, and it will also ride as before, with the velocity of the rollers; but remove the wedges, and let the roof fall upon the upper edges of the rollers, and it will now have two motions combined: for, first, it will ride in common with the ring on which it rests, in the way we have described; and, secondly, it will be urged by the rollers acting on its annular face, as so many toothless pinions, with a similar velocity with which it *rides* on the rollers, along with the ring; or, in other words, the roof will have *double* the *velocity* of the ring on which the rollers are fixed. To understand this effect more clearly, let the reader suppose himself in an open carriage. While he sits still, he is carried with the velocity of his vehicle; but if he should venture to place his foot on the circumference of one of the wheels, in getting out, while the vehicle is in motion, he will run the risk of being tossed forward by the said moving wheel with an *increased velocity*, that will convince him of the danger of such an experiment. This effect is familiar to all, but the cause is not generally considered, perhaps but little understood.

In order that the adaptation of all the parts that are connected with the rollers may be the more evident, we have given an enlarged section of one corner of the roof, near the eaves, within the ring of *fig. 4*, which, therefore, may be considered as a separate figure, in which the same letters represent the same parts as in *fig. 1*: namely, *a* is one of the rafters, forming one of the door-cheeks, projecting above the covering of the roof; *bb*, the roller, seen both in section and plan; *c*, a section of the fixed annular bed; *g*, a section of the moveable annular part of the roof, on which the eaves lie; and *gh*, an iron cranked bar, screwed to *g* above, and therefore moving with the roof, but in such way, that the crooked part at *h* lies just below an annular piece *i*, attached to the bed *c*; so that if any blast of wind, or other external force, should move the roof, it will be secured from oversetting, by the crank-bar at *h* catching the said fixed piece *i*; and if four or more of these crank-bars be used, the roof will be secure in all directions.

The objection which we have stated, as applying to the construction of Smeaton's roof, has very lately been obviated by the Rev. W. Pearson of East Sheen, Surrey, who has just finished a rotative dome, to receive a large and very accurate circular instrument for measuring azimuths, as well as altitudes, by Troughton; which instrument was originally ordered by the Russian Academy, but was countermanded by reason of the ravages committed by the French in Russia, at the time that the construction of it was in hand. This dome is represented in skeleton in *fig. 5*, where the circular rafters are seen at sixteen equal distances, exclusive of the opening, *aa*, which is nearly nine inches, through which the telescope of the instrument, placed on the top of the pillar *A*, is directed to any part of the heavens. This semicircular opening, which divides the dome into two equal portions, or quarters of an oblong sphere, is covered by five doors, two on each side, and one at the summit; but in such a way, that a small door on one

side faces a large one on the other, and the top door takes in five or six inches more on one side than on the other, so that there is no altitude to which the telescope may not be directed, by reversing the position of the dome, *i. e.* by turning it just half round, when necessary; and yet the fittings are so contrived, that any one of the doors may be opened, while the rest are shut. The two quarters of the oblong sphere are connected by brass bars at the points where the doors meet, and grooves are made on the edges of the rafters, that form the door-cheeks; so that any rain, that may be driven into the sides or ends of the doors, runs down these grooves to the eaves, and disappears, without being admitted within. We have not thought it necessary to shew these doors, which turn back on hinges, placed at their edges, upon the roof, which is covered first with triangular slips of deal about three-eighths thick, and then with tinned copper from Wyatt's manufactory; which metal being easily seamed, requires not the aid of many nails. The ornament at the top, being light, turns back with the top-door, and lies also on the roof, while observations are made in or near the zenith. The rotative part of this roof is of the simplest construction that can well be imagined, and yet is safe, and more free from friction than Smeaton's, though made with the utmost care. The ring of rollers is here entirely left out, and three large balls of lignum vitæ are substituted in a detached state, that is, without any fixed axis of motion, or pivots; and a four-sided circular tunnel is so formed of wood, that these balls, by their similarity of dimensions, keep their relative distances from one another, and act as friction-rollers both in a vertical and horizontal direction; nay, even in both at once, whenever they happen to come in contact with either of the sides of the said tunnel. The balls, which are  $4\frac{1}{2}$  inches in diameter each, are shewn in *fig. 5*, at opposite diameters of the dome, near the eaves, as though four were used, for the sake of exhibiting their mode of position and action; but three only are much better, because in every situation of their revolution they are certain to bear equal shares of the whole weight, when the bed is horizontal; and therefore none of them will refuse to move, when the dome is pushed round; but should they happen to gain ground of one another in moving forwards, by any difference in their diameters, they will resume their original situations respectively during the backward motion of the dome. *Fig. 6* is an enlarged scale of the tunnel and of one of the balls, in which *A* is a portion of the roof, terminated by the annular piece of deal *B*, which is lined with the annular piece of waincot *C*, to both which the covering-piece *D* above the eaves is screwed; *E* is a piece of waincot forming the inner side of the tunnel, and *G* is a continuation of one of the upright planks attached to the annular bed *H*, and forms the exterior side of the same. All the four sides of the square tunnel, which we called circular, because it surrounds the circular erection, are either of waincot, or lined with waincot, to come in contact with the lignum vitæ which composes the balls; though the rings of deal, *B* and *I*, might have been in contact with the balls, if they had been hard enough; but the weight of a dome, of nearly ten feet diameter, covered with copper, would, in that case, have produced hollow places, that might have impeded the uniform motion of the balls. The piece *J* is one of the supporters of the bed *I*, to which the deal planks *G* are made fall, and also the external pilasters that ornament the vertical portion of the structure. In this dome the velocity of the superstructure, as in Smeaton's, is double to that of the balls; and as these are left at liberty to turn in any direction, where an obstacle to motion is presented to any of them, they in-

stantly right themselves, and set forwards again with their load without impediment, and without groaning. A cranked bar attached to the piece E, and bending below a ring, fast to the bed I, but not shewn in the figure, prevents the dome from overturning by either accident or violence, and by the aid of a thumb-screw fixes it in any given position. This construction was, we believe, suggested first by Mr. Troughton, and as it has not been long in use, we cannot foresee what objections may hereafter apply to it; but we give the particulars of it from a persuasion, that it will be found to be a considerable improvement on Smeaton's, and that it may ultimately be generally adopted.

ROOFS, in *Rural Economy*, are formed of many different sorts of materials. Thatch was formerly almost in general use for covering the roofs of farm-buildings; but it is obviously objectionable on many accounts; it not only serves as a hiding-place for rats, mice, insects, birds, and other sorts of vermin; but it is extremely perishable in its nature, subject to be much damaged by high winds, and of course liable to frequent repairs, and, above all, highly dangerous from its combustible nature; it is, therefore, probably the most improper, the least safe, and, in the end, the most expensive material that can be employed for the purpose. Mr. Middleton, however, thinks that it keeps out the summer's heat and winter's cold more effectually than any other material now in use; but that, as it is not quite so compact and tightly as slates or tiles, and the straw being of such value for other purposes, it will probably be superseded by them. Tiles, though little exposed to danger from fire, do not, by any means, constitute a good roof, being ill calculated for preserving grain or other farm produce. In summer they admit a heat very unfriendly to hay, corn, or straw, while, in winter, they are equally objectionable, on the ground of transmitting moisture in a high degree, while slates, though more expensive at first, are liable to none of these objections, especially when of the more thick kind. A roof covered with them, therefore, answers every useful purpose, and is very durable, lasting half a century, with very slight repairs in any way.

In the Middlesex Report on Agriculture, it is remarked on this important subject, in speaking of the roofs of houses, that pantiles are so easily heated through by the sun during the summer months, that the rooms underneath are as hot as an oven; while, in the winter season, in every common frost, these tiles are so completely frozen through, as to become as cold as a covering of ice. These extremes must consequently have a very bad effect on the health of the inhabitants. The blue slates are so very thin, as to be equally liable to the same objection, particularly as they are now laid on most of our fashionable houses, under Wyatt's patent. They are rather better when laid on in the common manner, that is, on double laths, but much better on boards. Plain tiles make a considerably more temperate covering for houses than either pantiles or slates, by reason of their being laid double and in mortar, and thereby forming a much thicker and closer roof. In this they are nearly equalled by the thick or stone slating of the midland counties; they might also be glazed of a slate colour; in which case they would make a roof more handsome, temperate, and durable than any other covering material now known.

Some other substances have been had recourse to in this intention. In different parts of the country, cements of various kinds, and coarse paper laid over with resin, tar, &c. and other similar matters, have been tried, but with no very promising success as to their application. In some parts of Devonshire, though slate is by no means difficult to be pro-

cured, a substitute for that sort of covering is, Mr. Vancouver asserts, getting very much into use, which is prepared in the following manner:—three parts of whiting, five of sand, one of pounded charcoal, and one of bone-ashes, to a barrel of common tar, to which are added four pounds of black resin; the two last materials are to be melted together, and, when boiling, the other ingredients are to be added in small quantities, keeping them constantly stirred and in motion over the fire, until the whole mass becomes of a consistency fit for use. Then the roof, being previously covered over with sheathing-paper securely nailed down, is to be carefully and evenly spread with the liquid hot from the copper, to the thickness of about three quarters of an inch; which will cost, at the cauldron, about thirty-five shillings for each square of ten feet. The same measure of the common slate roof will cost about thirty-two shillings. The roofs for this sort of composition are pitched very flat, and, from the lightness of the scantling which is necessary in their construction, come considerably cheaper than those required for carrying slate or tiles.

Materials of the reed and heath kinds have also been tried as coverings for the roofs of farm-houses and cottages, in places where they are capable of being procured in sufficient quantities for such purposes; and, though they are considerably more durable than common straw thatch, they are subject to all the inconveniencies and objections of that sort of covering. Indeed, no kind of material that has hitherto been made use of for forming the coverings of the roofs of buildings are quite free from imperfections of some sort or other. It is consequently a matter of great individual, as well as national importance, to be acquainted with a substance which is not liable to any such defects, as a good, cheap, and durable material of such a nature, for this use would evidently be a most valuable discovery, as such a material is still clearly wanting for this purpose.

ROOF, *Attic of a*. See ATTIC.

ROOF, *False*. See FALSE.

ROOF, *Hip*. See HIP ROOF, and ROOF, supra.

ROOF-Trees, or RUFF-trees, are the timbers, in a ship, which go from the half-deck to the fore-castle. See ROUGH-Tree.

The term is also used for the upper timbers of any building; whence, in the northern counties, it is common to signify a whole family, by saying all under such-a-one's roof-tree.

ROOF-Tyles. See TYLE.

ROOFING, in *Rural Economy*, sometimes a word applied provincially to the ridge-cap of thatched roofs. It also signifies any sort of material employed in forming the roof of a building, whether in the frame-work, or covering. In the business of roofing farm or other buildings, the chief circumstance necessary to be attended to, is that of tying the two side-parts well together, and in a safe manner, by means of the wall-plates and binding-beams; especially those erections which are of the more long kind, without any cross-walls to stiffen and support them. It has been remarked, that it is generally for want of attention to these matters that farm-buildings, as well as those of other sorts, are so frequently seen propped up with shores and buttresses; or fallen to the ground half a century sooner, perhaps, than they would have done under a better and more judicious management. And it ought, indeed, to be a general principle, or line of conduct, which every careful and intelligent manager should follow in erecting such buildings;—a principle which is equally applicable to the other parts as well as the timber and the covering: which is, that of sparing no requisite expenditure; as a few shillings, or pounds, of additional

tional cost, in the first instance, may be the saving of ten times the sum in the end.

In the work of repairing buildings of this nature, the roofing claims equally the regard of the manager, with those of the foundations and other external parts. But the inside works, in all cases, more commonly and properly demand the notice of the occupiers.

ROOGEN, in *Geography*, a town of the duchy of Courland; 36 miles E.N.E. of Piltva.

ROOK, in *Ornithology*, a well-known bird of the crow-kind. See *CORVUS Frugilegus*.

Great care should be taken to guard against these mischievous birds at the time when the wheat is just shooting up; for they perceive it shooting much sooner than the farmer can, and are led by the shoot to pick it up. They must therefore be carefully kept off the ground until about a week or ten days after this season; for at the end of that time the blade will be grown up, and the grain so exhausted of its substance, that they will not give themselves any trouble to pick it out of the ground. They seldom or ever molest the wheat, which is sown about Michaelmas; because so much grain of the late harvest then lies scattered about the fields, that they find it much easier to pick up there, than to search for corn under ground in new-sown lands. They often do harm when the snow is going off from the green wheat towards the end of winter; for having been pinched for food during that season, they then greedily pluck up the young plants, in order to come at the remainder of the seeds still adhering to their roots; and are greatly assisted in this by the loose state of the earth at that time.

And they are also highly destructive to pea and bean crops in the early spring season, when they first appear above the ground, as they dig up the whole, both root and stem, even when considerably advanced in growth. They mull, therefore, be kept off with great care. A great many contrivances have been invented to frighten them away, such as feathers stuck up, the limbs of rooks scattered about the ground, dead rooks hung on sticks, the gun, a boy to halloo, and tofs a dead rook up in the air. Mr. Tull found this last to be the most effectual. It is probable, however, that firing at them frequently with a gun is the most certain means of deterring them from doing such injuries, as they have a great dislike to the smell of gunpowder.

It is remarked by Mr. Marshall, in his *Rural Economy of Norfolk*, that the method of frightening rooks in practice there, especially when they take to patches of corn, which are lodged before harvest, is simply to stick up a tall bough in the part infested; and if a gun be fired near the place, before the bough is set up, this simple expedient seldom fails of being effectual. And that if rooks make an attack after seed-time, or when they take generally to the crop before harvest, a boy is set to scare them; they being seldom attempted to be shot at in Norfolk; where a notion prevails, and is perhaps well founded, that rooks are essentially useful to the farmer, in picking up worms and grubs; especially the grub of the cock chaffer, which, it is believed, is frequently injurious to the meadows and marshes of that country. This opinion also prevails in other districts, and has most probably some foundation in truth, as they are often seen to follow the plough close to pick up such grubs.

It has indeed been stated, and supposed by some, that these birds do as much good by the destruction of grubs, insects, worms, and other similar sorts of animals, as they produce mischief by their attacks and ravages on the crops

of the farmer; an instance in favour of which is noticed to have occurred on the Yorkshire side of the county of Lancaster, where it is said they wholly devoured, destroyed, and removed some sort of insects, which, like locusts, had seized upon and taken possession of the grass-plants of a large track of grass-land in that neighbourhood in the early spring season, and nearly eat up and consumed the whole of it, to the very great alarm of the farmers of the vicinity; but which, on the first sight of the young rooks, were soon observed to be completely eaten up and destroyed, as was evident from the fresh grass quickly springing up and the surface becoming green again.

These birds are, however, in general considered as the greatest pests and plagues of the farmers in the above and some other northern districts, as they not only destroy the feed-wheat when newly sown, but drag out of the earth the spires of the grain or pulse seeds with them altogether, in the manner already suggested.

They are also, in these districts, equally destructive of the potatoe crops, both at the time of setting or putting them into the ground, and when they are coming up, as they eat and drag them out with great eagerness, thereby causing much irregularity and mischief in them. That they may sometimes, however, be useful in the above manner may readily be supposed; but they exist in such vast numbers in these, and some other parts of the country, that the ravages and injuries which they commit, very greatly preponderate over any good they are capable of performing in the ways that have been already stated.

They are, on the whole, an impudent and mischievous race of birds, with which, all the means the farmer can possibly take in the way of scaring them, are too often of very little avail. They frequently go to very great distances, so that the ravages they are productive of are of an extensive nature, and not confined to particular places or tracts of country only. The only safety for the farmer, therefore, seems to consist in the prevention of their breeding and rearing their young, and their destruction and eradication, as much as possible, in other ways. See *ROOKERY*.

ROOKE, LAWRENCE, in *Biography*, an able mathematician, was descended from a respectable family, and born at Deptford, in Kent, in the year 1623. He was educated in grammar-learning at Eton school, whence he removed, in 1639, to King's college, in the university of Cambridge, where he took his degrees. In 1650 he went to Oxford, where he had apartments in Wadham college, for the sake of improving in the society of Dr. Wilkins, and Mr. Seth Ward. He at length became a fellow-commoner of the college, and made it his principal place of residence for some years, during which he assisted Mr. Boyle in his chemical experiments. In 1652, Mr. Rooke was elected professor of astronomy at Gresham college, and in the same year he made some observations, at Oxford, on the comet which appeared in the month of December, and which observations were printed by Mr. Ward in 1653. In 1657, Mr. Rooke exchanged the astronomical professorship at Gresham college for that of geometry. He was one of the gentlemen by whose exertions the Royal Society was first formed, though he did not live long enough to see it established by the royal charter. Among the men of rank who cultivated his acquaintance was the marquis of Dorchester, who was not only a patron of learning, but very learned himself; and after the restoration, that nobleman frequently entertained Mr. Rooke as a visitor at his seat at Highgate, whence he used to bring him in his carriage every Wednesday to the Royal Society, which then met weekly at Gresham college. Mr. Rooke had always a tender constitution, and walking

from Highgate to London on a hot summer's day, he took cold, which proved fatal to him. He died in June 1662, in the 40th year of his age. He was highly esteemed by his contemporaries, as will appear from the following testimonies. Dr. Pope, in his life of Ward, bishop of Salisbury, speaking of Mr. Rooke, says he was profoundly skilled in all sorts of learning: "I durit," says he, "venture my life upon the truth of any proposition which he asserted, either in mathematics, natural philosophy, or history, for I never knew him affirm any thing positively, that was dubious. And when I have asked his opinion of an hypothesis, his usual answer was, I have no opinion. He was very modest, and sparing of his words, unless among intimate friends, and never talked idly. I may truly say I never was acquainted with any person who knew more and spoke less." Mr. Hooke places him among those who were most eminent for their knowledge and improvement of astronomy. Dr. Sprat, in his History of the Royal Society, speaks of him as "a man of a profound judgment, a vast comprehension, prodigious memory, and solid experience. His skill in mathematics was revered by all the lovers of those studies, and his perfection in many sorts of learning deserves no less admiration."

The only pieces which were published from his papers consist of "Observations on Cometæ, qui mensè Decembris Anno 1652 apparuit;" "Directions for Seamen going to the East and West Indies," which were drawn up at the appointment of the Royal Society, and inserted in their Transactions for 1665; "A Method for observing the Eclipses of the Moon;" "A Discourse concerning the Observations of the Eclipses of the Satellites of Jupiter;" and "An Account of an Experiment made with Oil in a long Tube." Ward's Life of the Gresham Professors.

ROOKE, Sir GEORGE, a celebrated naval commander, the son of Sir William Rooke, knight, of an ancient and honourable family in the county of Kent, was born in 1650. Though destined for another profession, a strong inclination for the sea-service induced him to enter into the navy. His first station was that of a volunteer, in which he distinguished himself by his undaunted courage and indefatigable application to business. He very soon obtained the post of lieutenant, from whence he rose to that of captain before he was thirty years of age, which was considered as a very extraordinary circumstance, at a time when no man, by his quality what it would, was advanced to that station before he had given ample testimonies of his being able to fill it with honour. These preferments he obtained during the reign of Charles II. and under his successor, James II., he was appointed to the command of the *Deptford*, a fourth rate man of war. His obligations to the Stuart family did not prevent his hearty concurrence in the revolution, and in 1689 he was appointed by admiral Herbert as commodore, with a squadron on the coast of Ireland. In this station he concurred with major-general Kirke in the famous relief of Londonderry. Soon after he was employed in escorting the duke of Schomberg's army, and landing them safe near Carrickfergus, facilitated the siege of that place, and, after it was taken, sailed with his squadron along the coast; where he first looked into the harbour of Dublin, manned all his boats, and insulted the place where king James was in person; and in the night of the 18th of September, he formed the design of burning all the vessels in the harbour, which he would certainly have executed, if the wind had not shifted and driven him out to sea. In 1690 he was, upon the recommendation of the earl of Torrington, appointed rear-admiral of the red, and in that rank he served in the fight off Beachy-Head, in which unfortunate affair it was admitted,

on all hands, that he had done his duty. He was employed twice or thrice to convoy king William to Holland, and in 1692 he was promoted to the rank of vice-admiral of the blue, when he served in the famous battle of La Hogue. This was on the 22d of May, and he behaved with such distinguished courage as to obtain the most marked applause of admiral Ruffel, it being owing to his vigorous behaviour that the last stroke was given to that important day, which threw the French entirely into confusion, and forced them to run such hazards, in order to shelter themselves from their victorious enemies. The next day was, however, still more glorious, for vice-admiral Rooke had orders to go into La Hogue and burn the enemy's ships as they lay. There were thirteen large men of war, which had crowded up as far as possible, and the transports, tenders, and ships with ammunition, were disposed in such a manner that it was thought impossible to burn them. Moreover, the French camp was in sight, with all the troops intended to have been employed in an invasion of this country, and several batteries upon the coast well supplied with heavy artillery. Notwithstanding all these preparations, admiral Rooke performed the business entrusted to him with so much skill and judgment, that he destroyed twelve ships of the line, and one fifty-six gun frigate. This desperate enterprise he effected with the loss of ten men only. The behaviour of the vice-admiral at La Hogue appeared to the king so great, and so worthy of public notice, that, having no opportunity at that time of providing for him, he settled upon him a pension of 1000*l.* per annum for his life. In 1693 the honour of knighthood was conferred upon him, and he was, at the same time, made vice-admiral of the red.

The grand fleet of the English and Dutch proceeding to sea in the month of May, Sir George Rooke was detached from it with a squadron of twenty-three ships of both nations, to convoy a large fleet of merchantmen up the Mediterranean. The French, in the mean time, had been indefatigable in repairing their losses, and with a very powerful fleet, of which the English ministry had obtained no proper intelligence, were lying in Lagos-bay, off Portugal, to intercept the combined fleet. On descrying the enemy, admiral Rooke ordered the smaller ships to make their escape into the nearest Spanish ports, and stood off under an easy sail for the protection of the rest. Two Dutch men of war, and a great number of merchant-ships, were captured; the conduct of the English admiral was, however, not only exempt from all blame, but he received the thanks of the merchants, and his promotion was not in the least impeded by this misfortune, which was owing to the mismanagement of the ministers. In 1696, having the chief command of the Channel fleet, he was ordered to prevent the Toulon fleet from getting into Brest, which, from the defective manning of his ships, he was unable to accomplish. On this account he underwent a long examination before the house of commons, but nothing appeared upon which a charge against him could be founded. He continued in command till the peace of Ryfwick, in 1697. He was chosen member of parliament for Portsmouth, and in this capacity he performed the duties of his station with activity and energy; however, as he mostly voted with the Tories, great pains were taken by the opposite party to ruin him in the king's opinion; but, to the honour of king William, when pressed to remove Sir George Rooke from his seat at the admiralty, he answered resolutely, "I will not." "Sir George (continued his majesty) served me faithfully at sea, and I never will displace him for acting as he thinks most for the service of his country in the house of commons:" an answer truly worthy of a British prince, as it tends to preserve the freedom of the constitution, and the liberty

liberty of parliament. In 1700 he was sent with an English squadron, in conjunction with a Dutch one, into the Baltic, to preserve the balance of power in the North, where a confederacy had been formed against Charles XII., the young king of Sweden. Rooke bombarded Copenhagen, and a peace being effected in the course of the year, he returned. In the following year he acted as commander of the Channel fleet; and being a second time chosen representative for Portsmouth, he continued to act with the opposition. This line of conduct was considered as highly meritorious with the ministry of queen Anne, who succeeded to the crown in 1702; and when war with France was declared, he was appointed as vice-admiral of England, to an united English and Dutch fleet, in an expedition against Cadiz, the duke of Ormond being commander of the land forces. The plan failed, probably for want of a proper degree of cordiality between the sea and land-service. Soon after, sir George obtaining intelligence that twenty-two Spanish galleons, guarded by a squadron of French men of war, were arrived in the harbour of Vigo, sailed thither; and sending a detachment of his fleet, with fire-ships, into the harbour, destroyed all the enemy's men of war, and a number of galleons, and took the rest. A vast booty was brought home, and a new coinage of silver, with the stamp *Vigo*, was issued as a national memorial of this brilliant success. On his return home, sir George Rooke was appointed to a seat in the privy council, and an inquiry having been moved in the house of lords into his conduct at Cadiz, it was voted that he had honourably discharged his duty.

In 1704 he was appointed to the command of the fleet destined to convey to Lisbon Charles, at that time competitor for the crown of Spain. Having performed that service he proceeded to the Mediterranean, where he cruised for some time. On his return through the Straits, he was joined by sir Cloudesley Shovel with a large reinforcement, and several schemes of further service being proposed, he determined to make a sudden attempt on Gibraltar. This he carried into execution in July, and the prince of Hesse, with the land forces, being disembarked on the neck, the ships proceeded to cannonade the fortifications at the mole. The enemy were driven from their guns, and a party of seamen landing, took possession of the batteries. The governor, intimidated by this bold and unexpected action, capitulated; and that important fortress has ever since remained in the hands of the English. Sir George Rooke then proceeded to Malaga, where he encountered the French fleet under the count de Toulouze. The numbers on each side were nearly equal in ships of the line, but the French were superior in men and guns. The engagement, which ensued August 13th, was undecided, neither party losing a ship, and each returned to their own ports.

Factions now ran high in the nation; and sir George Rooke, perceiving that as he rose in credit with his country, he lost his interest with persons in power, resolved to retire from public business, and prevent the affairs of the nation from receiving any injury on his account. Thus, almost immediately after he had taken the important fortresses of Gibraltar, and beaten the whole naval force of France in the battle of Malaga, he was constrained to quit his command: and as the Tories had before driven the earl of Orford from his post immediately after the battle of La Hogue, so the Whigs returned them the compliment, by making use of their ascendancy to the like purpose with regard to sir George Rooke. After this return for the important services he had done his country, sir George Rooke passed the remainder of his days as a private gentleman, and, for the most part, at his seat in Kent. "His zeal for the

church," says the discerning Campbell, "and his strict adherence to the Tories, made him the darling of one set of people, and exposed him no less to the aversion of another, which is the reason that an historian finds it difficult to obtain his true character from the writings of those who flourished in the same period of time. For my part, I have studied his actions, and his behaviour, and from thence have collected, that he was certainly an officer of great merit; if either conduct or courage could entitle him to that character."

In party matters he was perhaps too warm and eager; but in action he was perfectly cool and temperate, gave his orders with the utmost serenity; and as he was careful in marking the conduct of his principal officers, so his candour and justice were always conspicuous in the accounts he gave of them to his superiors; he there knew no party, no private considerations, but commended merit wherever it appeared.

In private life he was a good husband and a kind master, lived hospitably towards his neighbours and left behind him a moderate fortune: so moderate, that when he came to make his will, it surpris'd those that were present; but sir George exclaimed, "I do not leave much, but what I have was honestly gotten; it never cost a sailor a tear, or the nation a farthing." He died in January 1708, in the 58th year of his age, and was interred in the cathedral of Canterbury. He had been thrice married, and left one son only. Sir George Rooke has merited very highly the reputation of a brave and able seaman, who maintained the honour of the British flag, at a period when its superiority was much less decided than it has been during the present reign. Stockdale's edition of Campbell's *Lives of the Admirals*, vol. iv.

**ROOKERY**, in *Rural Economy*, a term applied to a nursery of rooks, or place where they build their nests, and collect in large numbers.

There are every where in many of the northern and other counties of the kingdom, numbers of such detestable nurseries of these mischievous and rapacious vermin, where they are suffered to breed and multiply in countless multitudes, to the great destruction of the hopes of the farmer and the nation at large. If it be necessary that such repositories of mischief be the produce of the husbandman should be preserved and kept up, for the vernal sport and amusement of their proprietors, certainly some other more certain and effectual means than those of the cross-bow kind should be had recourse to for the destruction of their young, in order that they may be kept sufficiently reduced and thinned in their numbers, to obviate, in as great a measure as possible, their baneful depredations and effects on the seeds and produce of the farmer.

The rooks fly from these despicable abodes, which are the head-quarters or dwellings where they collect and repose themselves, as well as breed, to very considerable distances, in order to execute and effect their different mischievous and rapacious attacks on the newly sown or rising crops of the husbandman, as they but seldom commit so much depredation on the fields which are near home.

They collect together during the severity of the winter season, especially in the more northern districts, from the different neighbouring small rookeries to be protected in large ones, and the woods which may happen to be near them; and thus render themselves secure at this inclement period, separating in the early spring to form their nests and breed in their particular rookeries.

In Lancashire, the whole track of the Fildes, as well as some others, is beset with these destructive and impudent

birds, from the vast rookeries and woods of Rawcliff-Hall and other halls in the same neighbourhood, without the owners of them ever suspecting that they harbour and support a breed of destructive vermin, which greatly injure and lessen the agricultural produce of the county. The same is also the case in a variety of other districts of the kingdom. Therefore some steps should be taken, either by severely taxing them, or some other means, in order that the mischievous consequences of such nurseries may be lessened, or wholly prevented, by their affording the convenience of breeding and rearing of so many of these birds.

**ROOKPOUR**, in *Geography*, a town of Bengal; six miles N. of Kishenagur. N. lat. 24° 28'. E. long. 86° 46'.

**ROOM**, in *Building*. See **BUILDING**.

**ROOM**, *Cook*. See **COOK-ROOM**.

**ROOM**, *Fruit*, in *Gardening*, a place constructed for the purpose of storing and laying up different articles of the fruit kind. Rooms of this nature are contrived in many different ways, but the best are perhaps those made with drawers and shelves for containing and preserving this sort of produce in all the different kinds and states of it. An ingenious plan and contrivance of this description has lately been suggested and delineated in the second volume of the Transactions of the Horticultural Society, by Mr. Maher, who has found it, in several years' experience, extremely useful in keeping fruit, especially of the apple and pear kinds.

It is represented as consisting of a long square form, the inside of which is fitted up, from the top to near the bottom, with drawers in different divisions, according to the size of the room. The number of each of the drawers is marked upon it, and a space left opposite to each such number, for inserting the name of the particular kind of fruit it may contain.

The lower rows of drawers have close bottoms, and are termed sweating drawers, as the fruit is put into them immediately after it is gathered, in order to undergo that operation. Then, in the course of ten or fifteen days, accordingly as the apples and pears may be found to have come forward, they are sorted, and the other drawers prepared for receiving them, by covering the bottoms of them with very clean wheat straw, which has been thoroughly ventilated and rendered quite dry in the open air. The bottoms of the drawers for this purpose are to be formed in open trellis work.

It is recommended, as saving much time and trouble in running up and down stairs, to have these rooms built upon the ground surface; and that the door and window of each should have slides, in order to admit a free circulation of air, when the weather is fine; but in damp days, or when it rains, the rooms should constantly be kept shut up in a close manner.

It is also advised, that a slate and pencil should hang in the rooms, the former of which should be divided into seven different columns, in which may be put down what fruit is delivered out each day in the week, for the satisfaction of families and servants.

Where these kinds of rooms are constructed with shelves, they should be formed of such sorts of wood as communicate no bad smells or tastes, and have thin slips of boards fastened on their fore parts to prevent the fruits from falling off from them. Some advise their being covered all over with a very coarse canvas, in order to prevent any sort of injury in the above way. The fruit is then to be laid singly in rows all over the surfaces of the shelves after being well dried, but never heaped over each other. Some

cover it by means of the same sort of canvas or by paper, taking care to turn it, and remove all that is damaged, two or three times during the winter season.

When the fruit is first laid upon the shelves, the earliest should be put upon the lowest shelves, and so on to the highest in their proper order. As this requires much time in many instances, it should always be done at every leisure period.

Many, however, think it the best way of keeping fruit, to first put it in glazed earthen pans, well packed and closed with covers, which are then to be placed on the shelves in these drying rooms.

These sorts of rooms should constantly be placed in the most convenient situations, and contiguous to the rooms designed for other sorts of garden produce.

**ROOMS**, *Flight of*. See **FUGUE**.

**ROOMS** in houses might be warmed by the steam of boiling water conveyed in pipes along their walls. See *Phil. Transf.* N° 476. p. 370. seq.

This contrivance is a copper with a still-head, and a lead or copper pipe fixed to this head, which conveys the hot steam of the boiling-water through the different rooms intended to be warmed.

**ROOMS**, in *Ship-Building*, the different vacancies between the timbers, and likewise those between the beams, as the mast-rooms, capitan-rooms, hatch-rooms, &c. Also the different apartments or places of reserve, of which there are a number in a ship, as the bread-room, an apartment in the hold abaft for containing the bread for the ship's use. The spirit-room is adjoining the after-hold, to contain the spirituous liquors for the ship's use. The captain's and lieutenant's store-rooms are two apartments built next each other on the starboard side of the after platform abaft, for those officers to stow their wine, &c. in. On the opposite side to the above is the steward's room, whence most of the provisions are issued, and which is the place appointed for the purser's steward to transact his business in. Sail-rooms are built between decks, upon the orlop or lower deck, to contain the spare sails. Besides these, there are several other store-rooms, in which the carpenter's, boatswain's, and gunner's stores are kept. Filling-room is a place parted off in the magazine; it is lined with sheet-lead, and therein the powder is stored, in order to fill the cartridges.

**ROOM and Space**, the distance from the moulding edge of one timber to the moulding edge of the next timber, which is always equal to the siding of two timbers, and the room or opening between.

**ROOMS**, in a military sense, are those parts of a building or barrack, which, by specific instructions, the different barrack-masters must provide, and furnish for the accommodation of the king's troops in Great Britain or elsewhere. The schedule, as published by authority, describes the number of rooms allowed in barracks for the commissioned, warrant, and non-commissioned officers, and private men, to be as follows:

*Cavalry Rooms*.—Field-officers, each two rooms; captains, each one ditto; subalterns, staff, and quarter-masters, each one ditto; the serjeants of each troop of dragoons, and the corporals of each troop of horse, one ditto; eight rank and file, one ditto; officer's mess, two ditto.

*Infantry Rooms*.—Field-officers, each two ditto; captains, each one ditto; two subalterns, one ditto; staff, each one ditto; twelve non-commissioned officers, and private men, one ditto; officer's mess, two ditto; serjeant-major, and quarter-master serjeant, one ditto. When there are a sufficient number of rooms in a barrack, one may be allowed to each subaltern of infantry.

ROONAY, in *Geography*, a town of Bengal; 33 miles S.E. of Ghidore.

ROOP, a term applied to signify a hoarfenef, such as happens among animals of the cattle kind.

ROOPAPOUR, in *Geography*, a town of Hindoostan, in Oude; 31 miles E.N.E. of Manickpour.

ROOPAT, a town on the E. coast of Sumatra. N. lat.  $1^{\circ} 3'$ . E. long.  $101^{\circ} 12'$ .

ROOPGUNGE, a town of Bengal; 34 miles N.N.W. of Dinagepour.

ROOPGUR, a town of Hindoostan, in Guzerat; five miles S. of Surat.

ROOPNAGUR, a town of Hindoostan, in the country of Agimere; 30 miles E. of Agimere. N. lat.  $26^{\circ} 39'$ . E. long.  $75^{\circ} 52'$ .

ROOPOUR, a town of Hindoostan, in the circar of Sirhind; 58 miles N. of Sirhind.

ROOS, PHILIP, better known by the name of *Rofa da Tivoli*, in *Biography*, was the second son of a painter, whose name was John Hendrick Roos; and he was born at Frankfurt in 1655. His early inclination to the art practised by his father, and the proficiency he exhibited, gained him the favour of the landgrave of Helle, at whose court the father and an uncle of Philip, called Theodore Roos, resided; and for whom they painted, conjointly, compositions of animals, landscapes, and figures.

This prince became the patron of Philip also, and presented him with a sum of money to prosecute his studies at Rome, from whence he never returned to repay the obligation. He married a beautiful woman, daughter of an historical painter, Giacinto Brandi, but was dissipated and extravagant.

He took up his residence at Tivoli, from whence comes his cognomen of *Rofa da Tivoli*, and there he imitated and combined the forms he met with. His pictures are generally made up of a group of sheep, goats, or cattle, a herdsman or woman, and a piece of building, illumined with strong contrasts of light and shade, and touched with uncommon spirit and freedom. That latter quality is their bane, for relying upon its effect upon the observers, and working generally from necessity, or the spur of the moment, he was tempted to rest satisfied with incorrectness and commonplace. His shadows are generally too dark and too brown, effected by leaving the dark ground upon which he worked; but the arrangements of his lights are ingenious and capitally executed, and the colour is frequently rich and full. He died in 1705, at the age of 50.

ROOSAND, in *Geography*, a town of Norway; 48 miles N.N.E. of Romfald.

ROOSEBURG, a small island in the Meuse; 3 miles N.E. from the Brill.

ROOT, (*RADIX*), in *Botany* and *Vegetable Physiology*, an important part of the vegetable body, being the basis of the whole, and what is first produced from the seed, when evolved by the process of germination. Its uses are, to fix the plant to a commodious situation, and to derive nourishment for its support. This organ is therefore perhaps indispensably necessary, at the first period of the growth of vegetables; and it usually continues to be so, at least amongst what are termed the more perfect kinds; the *Cuscuta*, or Dodder, being almost a solitary instance, of a phanogamous plant, parting with its root at an early age, and trusting for its future sustenance to the vegetable bodies on which it parasitically fixes. In some cryptogamous tribes the roots, though less discernible to us, are not the less effective for the performance of one or other of these functions. Thus, the crustaceous Lichens have not only a

considerable inequality of surface underneath, insinuating itself into every minute irregularity of the stone or bark over which they spread, but several of them have very distinguishable, fibrous, branched roots; witness *Lichen saxifragus*, Sm. *Transf. of Linn. Soc. v. 1. 82. t. 4. f. 4.*, and *L. tartareus*. The Submerged *Alga*, or Sea-weeds, seem, at first sight, to be merely fixed by their small disk-like roots; though many of them have branched and entangled radicles, insinuating themselves among pebbles at the bottom of the sea, which last may well be organs of nourishment, as well as of support. But even such as are fixed by a mere disk, are found, if cut down to that part, to sprout up again with all the rapidity and vigour of a full-grown shrub, treated in the same manner. Hence it appears that the disk in question must act as an organ for imbibing nutriment. That process indeed seems not to be accomplished, as usual, by the base, or under part, especially considering the nature and size of the bodies to which this kind of root is commonly attached. But something analogous may be observed in several parasitical plants of the *Orchid* family, (see *ORCHIDÆ*), whose thick fibrous roots lie naked upon the bark or branches of trees; and if they do imbibe a part of their sustenance from the latter, should seem also to be indebted considerably to the atmosphere, (to which a much larger portion of their surface is constantly exposed,) as sea-weeds are to the circumambient water. With the roots of parasitical ferns, indeed, as well as the supplementary radicles, thrown out from the climbing stem of the *Cuscuta*, the case may be different, as both are insinuated into the bark of the plants on which they grow. Floating sea-weeds, and abundance of fresh-water plants nearly related to them, agree with the *Cuscuta* so far, that after vegetating on some fixed spot, to which the parent seed attaches itself, they soon separate therefrom, and can derive nothing subsequently from thence. But being entirely disengaged, they can obtain matter of growth and nourishment, in future, from no other source, than the water in which they float. Who shall say whether such nutriment is absorbed by their whole surface; or whether the various and multiplied, fibrous or tubercular, appendages of their curious, and often complex, structure, may not, many of them, be analogous to the fibrous radicles, thrown out by the stems of the Dodder?

The most usual economy of the roots of plants is to be immerged in the earth, they having always a tendency to grow downwards, as stems in general have to ascend. Dr. Darwin's simple and luminous explanation of this phenomenon is quite sufficient, and precludes all others. He conceives that each part elongates itself in the direction in which it is most stimulated; the infant stem being most acted upon by air, the radicle by moisture.

A root commonly consists of two parts; the *caudex*, or body, and *radicula*, the fibre. The latter, generally greatly multiplied, branched, and extended, is the essential organ of nourishment.

The duration of roots is either annual, biennial, or perennial. Annual Roots, consisting chiefly of numerous fibres, belong to plants whose existence is limited to one summer, as Barley, and a vast tribe of field or garden flowers, many of which must occur to every one's recollection. Biennial Roots produce, the first season of their growth, only herbaceous, and living through the ensuing winter, bear flowers and fruit, or seed, in the following summer, after which they perish; for they never blossom or fructify but once, any more than annual herbs. Their existence indeed may be prolonged by accidents which hinder their flowering, year after year, in some cases; but after perfecting seed, or  
even

even blossoms, they die. Wheat, as cultivated with us, may be termed biennial; but is more properly an annual, which is sown and springs up the season before it flowers, as many annual weeds often do; while the seeds of others, perhaps of the same species, remain latent in the earth, awaiting the approach of spring. More genuine biennials are some species of *Verbascum*, the *Digitalis purpurea* or Fox-glove, &c. Perennial Roots belong to plants which live and blossom through many successive seasons, to an indefinite period, as is the case, not only with all trees and shrubs, but with many herbaceous plants, whose entire stems and foliage are frequently annual. Such are the bulbous roots of Tulips, Hyacinths, Anemones, &c. and the large fleshy ones of Rhubarb, and the *Gentiana lutea*, with many others, whose herbage dies every year entirely down to the ground; while other perennial roots, principally of a fibrous nature, are never deprived of herbage, as the *Gentiana acaulis*, *Lamium album*, and most perennial grasses. Several plants of hot climates, naturally perennial, and even shrubby, become annuals in our gardens, as the Common Nasturtium, *Tropaeolum*, which is capable of being increased by cuttings, nearly as well as by seeds, and thus its double-flowered variety is preserved. The same thing may be said of the *Hemimeris urticifolia*. The Tree Mallow, *Lavatera arborea*, wild in Pembrokehire, and occasionally seen in gardens, exemplifies, in a remarkable manner, the durability of the vital principle in seeds, as well as in biennial plants hindered from flowering. Nearly twenty years ago the seeds of this large and handsome shrubby plant were sown in a garden under our observation. From that period many of the young plants have, every year, sprung up, but the winter usually destroys them. A few have, now and then, survived a mild winter, and attaining a large size, have borne flowers, dying entirely at the end of autumn, nor do we believe that any of them has ripened seeds, so as to replenish the stock in the earth. At least this has not been the case for eight or nine years past. We have never taken the pains to shelter a young plant of this species in a stove, or green-house, through one or more winters; but Linnæus, with whom it was a favoured exotic, asserts that it will sometimes wait, for several years, for a prosperous flowering season, even in the open ground, though perishing afterwards, with the first cold, in spite of all the protection it can receive.

The *Caudex*, or Body of the root, in the Turnip, assumes the appearance of a stem, by rising considerably above the surface of the ground. Such is partly the case with onions, and many exotic bulbous plants. Linnæus speaks of the stem of a tree as a *caudex*, or root above ground. Perhaps the *caudex* may be as properly termed a subterraneous stem. This analogy nevertheless is scarcely correct, the line of demarcation being much more strictly drawn between an annual stem, and its perennial root, than between the branches of any tree and its trunk.

The fibres of the root, at least their growing extremities that imbibe nourishment from the earth, into which they are gradually and continually insinuating themselves, are, in every common case, strictly annual. The powers of roots lie dormant through our winters, or in bulbous plants, inhabitants of arid burning sands, through the summer of such climates. After they have begun to form fresh radicles, they cannot without destruction, or great danger, be transplanted; nor can even herbs with fibrous roots be safely removed, while their fibres are in a progressive state, very young annuals alone excepted.

Botanists, as well as gardeners and agriculturists, distinguish several kinds of roots, whose nature requires atten-

tion from those who wish to be masters of their economy or cultivation. The following are the principal heads under which they may be comprehended.

1. *Radix fibrosa*, a Fibrous Root, the most simple of all, consists entirely of fibres, undivided or branched, necessarily connected indeed by a common head, or by the base of the stem. These fibres convey nourishment directly to the stem or leaves. Such constitute, in general, the roots of grasses, and of most annual herbs; which latter requiring no reserved store of provision for another season, have no need of a *caudex* in which it might remain through the winter. While such roots exist, they keep growing, successively forming new fibres, as well as elongating their older ones. Their fibres are occasionally remarkably shaggy, or downy; whether to increase the surface for more ample absorption, or to fix the plant more firmly in the ground, we cannot always directly determine. Botanical experience has taught us, that very downy, or woolly fibres are especially appropriated to grasses that inhabit loose blowing sand.

2. *Radix repens*, a Creeping Root, is rather perhaps a subterraneous stem, branching off horizontally, extending itself at the extremity, and decaying at its origin, throwing out fibres as it goes, which are the efficient or actual roots. Such a root is extremely tenacious of life, as any portion of it will grow. Weeds which have this sort of root, as Couch-grass and Mint, are the most difficult of all things to eradicate, except perhaps the deeply descending roots, partly fleshy, of *Convolvulus arvensis*, and *Carduus*, or rather *Cnicus arvensis*, whose more vertical position enables them to run so far into the ground as to be hardly accessible. The widely creeping roots, well guarded with hard and durable sheaths, and supported by long woolly fibres, which belong to many sea-side, or sand, grasses, render such plants of great importance in the economy of nature. They bind down the loose sand, and form barriers against the encroachments of the ocean itself. The whole country of Holland is perhaps indebted for its very existence to such natural mounds, judiciously fostered and imitated by art. The three principal grasses that serve so valuable a purpose are *Carex arenaria*, *Arundo arenaria*, and *Elymus arenarius*, all plentiful on our sandy shores.

3. *Radix fusiformis*, a Spindle-shaped, or Tap Root, like the Carrot, Parsnep, Radish, and many common plants, of biennial, perennial, or more rarely annual duration. Its form is best calculated for penetrating deeply into the ground, or rather is owing to the resistance encountered by the young descending radicle. The *caudex*, of a fleshy juicy substance, abounding with peculiar secretions, and pregnant with the materials of the future herb, throws out numerous fibres, which are the real roots.

4. *Radix præmorsa*, an Abrupt Root, is nothing more than an oblong or spindle-shaped, vertical or horizontal, fleshy root, whose progress has been impeded, either by want of vigour, or by some mechanical interruption, so that it seems to have been cut or broken off. The name alludes to an ancient opinion of its having been bitten off, by no less a personage than "the devil," out of spite to mankind. Hence several plants, with such a root, were relied on for their supposed medical virtues, which nothing but heresy and schism could doubt.

5. *Radix tuberosa*, a Tuberos or Knobbed Root, is of various kinds. This sort of root belongs to perennial plants, its knobs, whether of themselves annual, biennial, or perennial, being reservoirs of nourishment, and of vital energy, in which the resources of the herb are husbanded through the winter. Such are the Potatoe, and Jerusalem Artichoke. Many of the Vetch or Pea tribe have

## ROOT.

have likewise small annual tubercles to their roots, by which these plants are enabled better to support the casual privations of a barren, dry soil. The knobs of Pæonies and *Spiræa Filipendula* are perennial, and analogous to bulbs. In the Orchis family they are biennial, whether simply oval, hand-shaped, or fasciculated; for in each case the plant of the season lives on that portion of its root which was formed during the preceding year, and meanwhile makes a new pair of knobs, or bulbs, to blossom in the following summer, or at least to produce herbage, whether circumstances may admit of flowers or not. There is reason to believe that certain species of this family, as the Linnæan *Ophrys spiralis*, often produce a mere tuft of leaves, without flowering at all, for many successive years, in spots which, in favourable seasons, are profusely decorated and perfumed with that charming little flower.

6. *Radix bulbosa*, a Bulbous Root, is often solid, as in the common *Crocus*, and its near relations *Isia*, *Gladiolus*, the splendid *Tigridia*, &c. In the Onion tribe, the bulbous root consists of concentric layers, enveloping one another, as also in the more solid root of the Tulip. The Lily has a fealy bulb, exactly analogous to the last; but as the leaves of this plant are narrow, and in some measure whorled, not sheathing, like those of the Onion and Tulip, the layers of its roots, having the closest affinity to leaves, assume a similar arrangement. The strict analogy of such coated or fealy bulbs with leaf-buds, indeed one might almost say their identity, appears from the fealy axillary buds of the Orange Lily, and other species, formed on the upper part of the stem, which, falling to the ground, become actual bulbous roots, without any transformation. Similar buds in *Dentaria* become, by a slight alteration, the tuberous fealy root proper to that genus. The constitution of bulbous roots is admirably suited for plants inhabiting hot sandy countries, subject to long drought. After flowering, their withered herbage serves like wings to disperse them far and wide, till the first rains cause them to fix their sprouting radicles in the moistened soil, where they speedily put out fresh leaves and blossoms, during the favourable season; after which their life and energy are locked up again in the bulb, or perhaps multiplied in seeds, for the succeeding year. The seeds of the *Isia* and *Gladiolus* families are no less admirably adapted to the circumstances of their sandy and windy country; such as are winged being readily waisted, and the large polished round kinds, as extensively rolled, over the open deserts which they are appointed to adorn.

7. *Radix articulata*, or *granulata*, a Jointed or Granulated Root, does not essentially differ from a fealy bulb. The Wood Sorrel, *Oxalis Acetosella*, for instance, has, as it were, a fealy bulb, pulled out into an oblong form, and connected by a thread; while the *Saxifraga granulata* has a series of subterraneous buds, like solid bulbs. *S. cernua* and *bulbifera* have axillary buds, formed on their stems, like *Dentaria*, which become granulated roots.

The object of Nature is nearly the same throughout all these seemingly different productions; to establish a reservoir, in which the vital force of the plant, as well as its material resources, are stored up; till the former is strengthened, in consequence of suspended action, and the latter are matured by rest. Such assistance is occasionally afforded to plants whose roots have naturally hardly any thing of a fleshy substance, whenever they are exposed to danger from vicissitude, or from interrupted supplies. Thus grasses with fibrous roots, accidentally stationed in a soil too dry or fluctuating, have a power of becoming bulbous. For the same reason, bulbous roots, when desired to be had in great size or perfection, should first be supplied with plentiful nourishment,

and then be checked in the too luxuriant growth of their herbage. By some treatment of this kind, exotic bulbs, which seldom afford flowers in our gardens or stoves, because of the uniformity of their languid existence, may perhaps be made to blossom more frequently than they do. Sudden and abundant supplies of heat, food, or moisture, and as sudden checks of one or the other, at the discretion of the cultivator, are likely to have this effect. In general, an interruption of the luxuriance of a root, favours its production of flowers and of seeds. The latter are seldom perfected in the more luxuriant sorts of Mint, except by greatly restraining the growth of the roots, in a garden-pot, dry border, or otherwise. The bulbous likes will often form seeds, if their buds are stripped off, but seldom in their ordinary state of culture.

A just attention to the nature and constitution of each different kind of root, will teach us to understand its best mode of cultivation, transplantation, &c. and will account for those general practices, founded on experience, which are too well known to require illustration here, and properly come under the notice of the agriculturist and gardener.

Root, in *Husbandry*, the lower part of a plant, or that which is in the ground, and by which it adheres to the earth, draws its nourishment, and transmits it to the other parts. For the method of clearing lands from the roots of trees, under-wood, &c. see *RECLAIMING Lands*.

It may be noticed, that the roots of plants are of use to them principally in two respects, namely, to give them stability in the ground, that they may not be displaced, or blown down by high winds, or other accidents; and by their spreading in the ground, for collecting, and perhaps in some measure preparing, food for the whole plant. Plants are, however, in part fed or nourished from the air, fine vapours, dews, &c.; which enter by their leaves and branches, but principally by what is absorbed and taken up by their roots: for which reason the farmer takes infinite pains to prepare the land by tillage and manure, whereby it is opened, pulverized, and not only made more easily penetrable for the roots to spread in, and collect their nourishment, but rendered more proper for being impregnated with such matters, as well as for retaining and conveying them to their fibrous roots in order to be drank up.

Roots, in the intention of the farmer, may also be divided into two sorts, namely, perpendicular or tap-roots, which penetrate deep, and run down into the ground, usually singly, such as carrots, parsneps, and the roots of some trees, as the oak, &c. And those that divide near the surface of the ground, and spread out in it in various directions, which are called horizontal and fibrous roots, and if very small, capillary roots. The tap-roots have also fibrous roots issuing from their sides, all round the tap-root; and these lateral roots are longest near the surface of the ground, and gradually shorter as the tap-roots descend deeper into the soil.

And further, the surfaces of roots are soft and spongy, more particularly in the small or fibrous roots, and these are furnished with absorbent vessels, the mouths of which drink up the vegetable food, and distribute it to all parts of the plant. As the large roots are more close and hard on their surfaces, it would appear that they are chiefly intended for the support and stability of the plant, while the fibrous roots collect the nourishment for the support of the plant as well as the large roots. The branches of roots are formed with their extreme ends pointing from the stem of the plant, and hence it appears that roots, when once well formed, do not afterwards increase, or extend further longitudinally; they lengthen at their ends, but not at their intermediate

## ROOT.

intermediate parts, for if they did, the branches, being left behind, would be drawn back, with their ends pointing towards the stem; but they are constantly found in a contrary position, with their ends pointing in a direction from the stem. If a root is cut it extends no farther in length, as already observed, but new roots are formed near the cut end of the old root; two or more new or young roots being formed in the room of the former old one. Hence the fibrous roots of plants are multiplied by cutting them with a spade or hoe; and this is often a great benefit to the plant. The pores of the fibrous roots are the mouths of the absorbent vessels, by which the whole plant is fed, and the more they are multiplied the more nourishment they collect for it.

And thus a plant that naturally extends its roots to a considerable distance, is in danger of being killed by transplanting, unless it is also furnished with fibrous roots, which must be carried with it to the new ground; or new ones must be formed to make the plant thrive. Hence it is that plants which have long straggling roots are removed with difficulty; but plants of the same kind and age, and that grow in the same ground, are transplanted with safety and success, if they have been previously dug round with a spade, whereby their fibrous roots have been cut and multiplied, so that they rise with a ball of earth adhering to them.

Besides, there is a communication between the different roots of a plant, as when some of them are well nourished the others are benefited thereby. If some of the roots of a plant be laid in dry earth or sand, and others in water, the latter will furnish the dry roots with water sufficient to keep them and the earth about them moist, so long as they have a supply of water; it is for this reason that deep rooting plants are little affected by drought; the tap-roots finding moisture below, send some of it up to the roots near the surface; for which reason, also, lucern and fainfoin flourish in dry hot weather, in which common grass, and other fibrous-rooted plants, that do not descend deep, are scorched and burnt up. And as roots communicate moisture to each other, they therewith also communicate nourishment; for it is found by experience, that drilled plants, well hoed on each side of a row only, are better nourished than sown plants standing at equal distances, or upon an equal surface of ground with the drilled, and not hoed. Besides these sorts of roots, some kinds of grain, as that of wheat, have them double, or what may be termed two sets; the first coming directly from the grain or seed, while the latter shoots some time afterwards from the top or crown. Hence they are denominated *feminal* and *coronal* roots. The feminal root is, Dr. Hunter says, pushed out at the same time with the germ, which, together with the farina, nourishes the plant during the winter, before the crown and coronal roots are formed. But that in the spring, when the crown has become sufficiently large, it detaches a number of strong fibres, which push themselves obliquely downwards. These are the coronal roots serving to nourish the plant till it arrives at maturity. And he adds, that a small pipe preserves the communication between them and the feminal roots. This makes an essential part of the plant, and is observed to be longer or shorter, according to the depth that the seed has been buried. But on the contrary, it is remarkable, that the crown is always formed just within the surface. Its place is the same, whether the grain has been sown deep or superficial. And that as the increase of this sort of grain depends upon the vigorous absorption of the coronal roots, it is obvious why they fix themselves so near the surface, where the soil is the most rich, and contains

the largest proportion of nutritious substances. It is also evident, that as this sort of grain must be exposed to the severity of the winter season, its roots are admirably disposed to withstand its effects.

It is evident, that these facts, and those connected with the nature of the roots of different plants of the grass kind, lead to many important considerations in the practice of the farmer, and fully shew the necessity as well as utility of his being perfectly acquainted with the nature, form, and mode of growth of the roots of such plants as have been introduced into the field culture.

All those sorts of fleshy roots which run to a considerable depth in the ground, as is the case with the carrot, parsnep, beet, mangel wurzel, liquorice, and some others of the same nature, constantly require a great depth of cultivation and tillage to secure good and full crops. And the various less fleshy roots, which run deeply in the earth, such as those of beans, hops, parsley, red clover, lucern, fainfoin, and many sorts of grasses, as well as the common and Swedish turnip, &c. also stand in need of a rather fine and deep preparation of the soil in order to afford equal and full crops.

Among the grain kinds of crops, wheat, from the nature of its root, demands the deepest and finest tillage; but neither this nor any of the others require any great depth of ploughing merely on that account, as the roots always spread out very near the surface. The same is the case with most of the cabbage sorts, yet the land should always be well prepared for them.

Much difference of opinion has been entertained by different inquirers respecting the cause of the constant downward direction of roots and the upward growth of stems. Some have supposed it to depend on the quality of the sap juice which circulates within them; others have, with greater ingenuity and plausibility, asserted it to be owing to the living principle or power in them, and the stimulus of the air and moisture upon different parts of them. And more lately, and with still greater probability, it has been attributed to circumstances of a mechanical nature, as depending on the principle of gravity. This notion has been beautifully illustrated and explained by the experiments of Mr. A. Knight, by placing moistened beans in favourable situations for vegetating upon the circumferences of wheels moving with different degrees of velocity in vertical and horizontal positions.

The roots of large old trees, which have been felled, are often got out of the ground in a cheap convenient manner by blasting or blowing them with gunpowder, by means of a boring auger contrived for the purpose. See **BLASTING**.

Roots, in *Gardening*, are of many different kinds, which vary considerably in their nature. They mostly consist of a stock, or thick main part, which strikes into the earth or soil, and of fibrous or thread-like parts, which terminate, and are sent off from different portions of it, spreading themselves to great distances in the ground, for the purpose of collecting the nourishment and support of the particular plant.

The peculiarities of structure, and the direction in the stock parts of roots, have led to several distinctions in regard to their kinds.

In this way we have *perpendicular* and *horizontal* roots, or those which descend and run down into the earth or soil in a straight downward direction; and those which run or pass along under the surface of the ground in a superficial transverse manner: *simple* and *compound* or *branched* roots, or such as are perfectly single, and without any sort of subdivision in their parts, and such as are divided in a lateral

lateral branched manner, with many subdivisions and ramifications: *spindle-shaped* and *tapering* roots, or those which have oblong thick upper parts, which taper in a regular gradual manner to the lower extremities: of this nature are the roots of the common radish, the parsnep, the carrot, and many others: *bulbous* and *tuberous* roots, or those which have a roundish, oval, swelling, bulbous form, and which are composed, in some cases, of many succulent imbricated scales, and in others, of numerous involving coats, including three distinct sorts, as scaly bulbs, having the parts lying over one another, as in the root of the lily; tunicated bulbs, which are formed of several different tunics or coats involving each other in a close manner, as in the onion; and solid bulbs, as in the tulip; and those which are of a thick, fleshy, knobby, solid, lumpy form, whether of a roundish, irregularly knobbed or oblong shape, whether constituted of only one knob, or of several collected into bundles: examples of these sorts are met with in the roots of the potatoe, the Jerusalem artichoke, anemone, pæony, &c. as well as in all those which are made up of a solid fleshy substance: *fibrous* and *creeping* roots, or such as are wholly composed of numerous radical or slender fibrous parts, and are the most common sort, especially in various descriptions of herbaceous plants, consisting of roots of the perpendicular, horizontal, simple, and branched kinds; some of which are very thin and fine, like threads, others somewhat of a fleshy nature; and such as run along immediately under the surface of the ground to a considerable length or distance, emitting and sending forth at certain points small fibres below and shoots at the upper parts: *globular* and *bundled* roots, or such as have roundish, fleshy, solid roots of the tuberous description, as in the earth-nut, &c. and such as are composed of many small, oblong, fleshy kernelly parts or knobs, which are all connected on the upper part, and terminated underneath in radicles or fibres, as in the ranunculus, &c.: these are also often termed *grumous* roots: *granulous aggregate* and *pendulous clustered* roots, or those which consist of many roundish knobs, like grains of corn, the whole of which is congregated together, so as to form a root; and those which are composed of several roundish fleshy knobs or tubers, which are strung on and suspended, as it were, at the ends of fibres, as in the asphodel and many others: *banded tuberous* and *testiculated* roots, or such as have oblong tuberous forms of them which divide and spread out like an open hand, and such as are composed of two roundish, egg-like, tuberous knobs, united in somewhat a testiculated manner: *jointed* and *woody* roots, or those which are long, thickish, and jointed at certain distances; and those which are constantly becoming of a hard, tough, woody nature, as those of most trees, shrubs, and under-shrubs: and *downright* or *tap* roots, or those which have a main fleshy part, that runs directly downwards in a perpendicular manner, as in the carrot, parsnep, beet, &c. as well as in some sorts of trees and shrubs.

Garden roots are likewise further divided and distinguished according to the time of their duration or lasting in the soil or ground. In this respect, there are *annual* roots, or those which continue or endure for one year only, at the farthest, and then wholly perish and decay, as in all the annual plant kind: *biennial* roots, or such as continue and last out for two years, or thereabouts, only, after which they entirely decay and are destroyed; and *perennial* roots, or such as are of many years' duration or continuance. In some cases of this nature both the roots and stems are perennial, while in others only the former.

Roots of the garden description, for the most part, penetrate and insert themselves into the soil or ground, in order

to draw and derive nourishment and support from it; but there are some few which form exceptions to this rule, as the root of the milletoe, which attaches and fixes itself to the branches or other parts of trees, being inserted between their bark and wood, whence it acquires its means of support, the stem proceeding in a downward direction from it, &c.

In bulbous roots of different kinds, there are great differences in regard to their habits of growth, in so far at least as relates to the depths which they require to be in the earth or soil; some standing in need of being quite superficial, while others necessarily descend to considerable depths below the surface. These circumstances therefore probably require much greater attention in their cultivation than has hitherto been bestowed upon them, in order to procure good roots of such kinds.

The roots of different kinds of garden plants require to be taken up at particular seasons, and to be kept and preserved for use in different manners, according to their different natures, and the purposes for which they are intended. All the roots of the different flower bulb and tuberous kinds may be taken up when the stalks decline towards the end of summer, or the beginning of the succeeding season; they should then be rendered perfectly dry by some gentle means, such as exposing them to a dry current of air and a middling degree of heat, when thinly spread out in a sieve, or some other convenient manner; afterwards, when this has been perfectly accomplished, they may be put into drawers in dry situations, or hung up in bags in similar places.

Bulbous culinary roots of the onion kind have been attempted to be kept in many different ways, as by laying them thinly in dry rooms, roping them and hanging them up in dry airy places, and burning or charring the root parts of the bulbs; but they seem not to be capable of being long preserved without shooting while in the open air, in any way that has hitherto been made trial of in such intention. The best methods of proceeding with them are probably those of taking them from the ground after some dry weather, exposing them thinly to the sun and air until they are become, in every respect, perfectly in a state free from any sort of mould or moisture, and then either to have them roped and hung up, or spread out in a thin manner upon a dry boarded floor. The warmth or heat of the sun or fire should never be suffered to penetrate into the places where they are kept, but they should be naturally dry.

Tuberous roots, such as those of the potatoe, in the general keeping crop, should always be taken up during a dry season, and be afterwards, as quickly as possible, by mild means, made thoroughly dry and free from any mouldy matter that may hang about them, when they may be laid up in any place which is free from damp, taking care to cover them sufficiently thickly with dry straw when the weather is frosty. Roots of the Jerusalem artichoke, and other similar kinds, may be preserved in the same way, but without the use of the straw, as they do not stand in need of it.

Perpendicular and tap-roots, such as those of the carrot, parsnep, beet, and others of the same fleshy kind, sometimes require to be laid up in order to preserve them in a juicy moist state. This is best accomplished by the use of dry light sand, or other similar materials of a light dry nature, packing them up in layers one over the other, each sort together, in a separate manner. In this way they may be well preserved in a state fit for constant use. The roots of celery and cardoons may also be preserved in the same way with much success and advantage when necessary.

## ROOT.

It is occasionally necessary that the tap-roots of feeding plants, while they are in the nursery, should be shortened, with the view of preventing their striking down too deep into a bad subsoil, as well as to force out lateral horizontal roots in greater abundance nearer to the surface of the ground, where the soil is good, that they may derive more full nourishment and support, and thereby thrive in a better and more expeditious manner.

The roots of annual and biennial plants stand in need of being renewed every year, or at the end of every two years, by the sowing of their seeds, or the setting of some other part of them: and the perennial roots are continued by the parting, dividing, slipping, cutting, and resetting of them or their different parts, as well as by various other methods, as may be seen fully described under their different proper heads.

**Roots, in Medicine.** The principal roots used in the practice of physic, are rhubarb, rhaponticum, sarsaparilla, ipecacuanha, jalap, zedoary, galangal, cassimena, gentian, turmeric, liquorice, madder, &c. See RHUBARB, SARSAPARILLA, IPECACUANHA, &c.

There are several ways of preparing roots for medicinal use in the eastern nations, which strongly alter them from their original form and appearance. An instance we have of this in the drug called salep, which is no other than the root of an orchis thus prepared.

Other roots they also prepare in the same manner, or something like it; an instance of which we have in some of the oriental ginseng, which is clear and pellucid, as a resin, and friable like one, retaining very little of the structure or appearance of the root. Kämpfer gives the method by which the people in the East do this, and it may be well worth trying on some of our own roots.

The Chinese, this author informs us, give their ginseng its colour and transparency in this manner. They macerate the fresh root for three days in cold rice-water, then expose it in close vessels to the vapour of the same water; after which they carefully and leisurely dry it, and it becomes hard and brittle, of a brownish-red colour, and as transparent as a resin.

All the ginseng of China is not of this sort; and it has been supposed by some, that such as was so had assumed that appearance by age, as many of the more succulent roots, which have very small fibres, will become much less opaque when perfectly dry than they were at first; but experience shews that this is not the case; for many persons have kept the oriental ginseng a great many years, but it has never been known to assume that appearance. There is no doubt, however, but that if the West Indian ginseng were treated in this manner, it would equal the prepared ginseng of the East; for the roots of some of our umbelliferous plants, particularly the skirret, may be made clear and transparent in this manner, by only boiling it in common water, and afterwards drying it in the open air. Mem. Acad. Scienc. Par. 1740.

**ROOTS, Flower.** See FLOWER.

**Root of Osteocolla,** a word used to express a sort of soft and rotten matter, on which the osteocolla of Germany is found in sandy grounds.

The workmen seek after the osteocolla by the direction of certain lumps of a white marley matter, which they find lying on the sands; under this they always find a parcel of rotten vegetable matter, branching out from a main stem or trunk, at ten or twelve feet deep up to the surface; this rotten substance they call the root of the osteocolla; and they observe, that where the matter they seek after is not found round it at the time of their digging, they need only mark

the place, and dig again a year afterwards, and they will find it formed in a perfect manner. The osteocolla found near Frankfort is all of this kind; and we find the holes in the centre of all the pieces through which this root had passed. It is so tender, that it usually moulders away on the osteocolla being exposed to the air; but sometimes they wash it out. Phil. Trans. N<sup>o</sup> 39.

It is not easy to conceive what this is, unless the remains of fossil branches of trees; but even then it is as difficult to account for the formation of the osteocolla about them, as there is none of it found concentered where they are not. We have a sort of osteocolla found with us in what we call *petrifying springs*; but as this is done in the water, it is easier to conceive how it becomes so pure, than how a soft and pappy substance, found in the midst of a bed of sand, comes not to have some sand embodied in it.

**ROOT, Indian Arrow.** See ARROW-root.

**ROOT, China.** See SMLAX.

**ROOT, False China,** a species of *Senecio*; which see.

**ROOT, Fever,** a species of *Triosteum*; which see.

**ROOT, Hollow,** a species of *Adaxa*; which see.

**ROOT, Rose.** See ROSE-root.

**ROOT, Seminal.** See SEMINAL.

**ROOT, Snake.** See SNAKE-root.

**ROOT, Black, or Wild Snake,** of America, a species of *Actea*; which see.

**ROOT, Dr. Witt's Rattle-snake,** a species of *Prenanthes*; which see.

**ROOT, Senegaw Rattle-snake,** a species of *Polygala*; which see.

**ROOT, Sweet,** a species of *Glycirrhiza*; which see.

**ROOT of Scarcity,** in *Agriculture*, the common name of a plant of the tap-rooted fleshy kind, that has much resemblance to the beet, and which is now cultivated to a very large size both in the root and top, as cattle food, where a proper sort of feed is provided. It is a very hardy vegetable, is easily grown, and much relished by horses as well as neat cattle. See MANGEL Wurzel.

**ROOT-Crops,** such sorts of field crops as afford their produce in roots, such as potatoes, turnips, carrots, parsneps, &c. These sorts of crops constantly require to have the ground peculiarly prepared for them. See these several heads.

Some of the crops require that the land be well pulverized and prepared before they are put into it, and afterwards to have the mould well stirred and laid up about them while they are growing. They should also, in many instances, be at first, or in a gradual manner, thinned, set out, and left at suitable distances for gaining their full and perfect states of growth. Some of them stand in need of being regularly taken up out of the ground at the proper season and stored up, as the potatoe, carrot, parsnep, beet, &c. while others may often remain in the soil until they are consumed, as the various sorts of turnips, and some others, not only without sustaining any great injury, but sometimes with much benefit. The Swedish turnip is, however, frequently stored up with utility and convenience. When laid up they require to be in a dry condition on the outside, and to be deposited in dry situations. Potatoes should always be kept dry and secured from frost, by means of straw or other similar matters being laid round them.

**ROOT-Grafting.** See ENGRAFTING.

**ROOT-House,** in *Rural Economy*, the place where roots are deposited for the more readily supplying live-stock of different kinds with them. It is of much consequence to the farmer to have this place as near as possible to the stables, feeding-houses, and cattle-sheds. These houses are essentially necessary

# ROOT.

necessary wherever there is a number of cows or other sorts of cattle to be supported on roots of the carrot, parsnep, turnip, and potatoe kinds, as well as for cabbages, as without them it would not be only inconvenient, but in many cases, in severe weather, impossible to provide them for the daily supply of such stock. The cabbages should not, however, ever be kept long in these houses, as they are very apt to take on the putrid fermentation, and become useless. The farmer should be careful that the yard-man constantly keeps such places perfectly clean and sweet, in order that the roots may contract no bad smell, as cattle are in many cases extremely nice in their feeding, and when once disgusted with any sort of food of this kind, seldom take to it again in a proper manner.

Root-houses are always the best and sweetest when laid over on the insides with a coarse plaster, or boarded with some rough common boarding material. They may in many cases be divided for different sorts of roots, with great advantage and convenience. The doors of them should for the most part be large, so that the carts may be backed and readily emptied in at them without any difficulty.

Root, in *Arithmetic* and *Algebra*, denotes a quantity which, being multiplied by itself, produces some higher power, and it is called the 2d, 3d, 4th, &c. root, according to the number of times that the multiplication by itself is performed, that number being always one less than the denomination of the root: thus, if a number is multiplied once by itself, it is called the square root, or 2d root of the product; if twice, it is called the cube, or 3d root; if three times, the biquadrate, or 4th root; and so on to other roots, which, beyond the 4th, are commonly denoted by the 5th, 6th, &c. root; though ancient authors, and even some modern ones, use particular denominations for all higher roots, as we do for the square root and cube root. Thus, the

2d root,	is called the <i>square</i> root.
3d root	— <i>cube</i> root.
4th root	— $\left\{ \begin{array}{l} \text{quadrato-quadratum, or biqua-} \\ \text{dratic root.} \end{array} \right.$
5th root	— <i>surfolid</i> root.
6th root	— <i>quadrato-cubo</i> .
&c.	&c.

But such distinctions are useless, and are, therefore, now commonly omitted.

For the method of extracting the roots of numbers, see the articles APPROXIMATION and EXTRACTION; and for a table of the square roots and cube roots of numbers, see the conclusion of this article.

Roots of Equations, in *Algebra*, denote such a number or quantity as, when substituted for the unknown quantity, will produce an equality between both sides of the equation: thus, in the equation

$$x^3 - 6x^2 + 11x = 6, \text{ or } x^3 - 6x^2 + 11x - 6 = 0;$$

if we substitute 1 instead of  $x$ , we have  $1 - 6 + 11 = 6$ ; therefore 1 is a root of that equation: if we substitute 2 instead of  $x$ , we have  $2^3 - 6 \cdot 2^2 + 11 \cdot 2 = 6$ ; therefore 2 is also a root of the same equation: and if we substitute 3 for  $x$ , then  $3^3 - 6 \cdot 3^2 + 11 \cdot 3 = 6$ ; and, therefore, 3 is likewise a root of the same equation: hence the roots are 1, 2, and 3; that is, there are three distinct numbers, which, when substituted for  $x$ , will produce the equality required. And it is the same in all equations, viz. it has always as many roots, real or imaginary, as there are units in the index of the highest power of the unknown quantity. This property has place in equations of the most simple forms, as  $x^2 = 1$ ,  $x^3 = 1$ ,  $x^4 = 1$ ,  $x^5 = 1$ , &c. each of these

having as many roots as there are units in the exponent of the power: thus, the

two square roots of 1, are  $+1$  and  $-1$ ;

three cube roots of 1, are  $1$ ,  $-\frac{1}{2} + \frac{1}{2}\sqrt{-3}$ , and  $-\frac{1}{2} - \frac{1}{2}\sqrt{-3}$ ;

four 4th roots of 1, are  $1$ ,  $-1$ ,  $+\sqrt{-1}$ , and  $-\sqrt{-1}$ ;

five 5th roots of 1,  $\left\{ \begin{array}{l} \text{are } 1, \frac{-1 + \sqrt{5}}{4} \pm \sqrt{\left\{ \left( \frac{-1 + \sqrt{5}}{4} \right)^2 - 1 \right\}} \\ \text{and } \frac{1 - \sqrt{5}}{4} \pm \sqrt{\left\{ \left( \frac{-1 - \sqrt{5}}{4} \right)^2 - 1 \right\}} \end{array} \right.$

the two latter forms containing each two roots, in consequence of the ambiguous sign,  $\pm$ , which enters into their composition.

The doctrine of the roots of equations is one of the most intricate, but at the same time most interesting, of any branch of algebra. The method of finding the roots of quadratic equations is found in the earliest algebraic authors; it is even given, though somewhat different in form, in the *Bija Ganita*, a Sanserit algebra, written about the latter end of the 12th, or the beginning of the 13th century, translated into Persian in 1634, and lately into English by Mr. Strachey, of the East India Company's Bengal civil establishment. The solution of cubic equations was first published by Cardan about 1540, though it is clear that he was not the inventor of the method, having received it from Tartaglia, who is commonly considered as the real author; however, Lagrange attributes the general investigation to Hudde, a celebrated Dutch mathematician, a contemporary of Descartes and Fermat. Equations of the 4th degree were first solved by Ferrari, a pupil of Cardan's, and published by the latter in 1540; since which time no further extent has been given to the subject, the 5th, and all higher equations having resisted the whole accumulated power of the modern analysis. Still, however, many important properties of the roots of equations have been discovered; the whole theory has been reduced to one uniform principle of operation; and approximations have been made in all those cases where direct methods of solution were unattainable. We cannot, of course, enter upon this subject at any great length; but a summary of the most interesting particulars, though not accompanied, in all cases, with their demonstration, will not, we presume, be unacceptable to the general reader; in the enumeration of which we shall avail ourselves of the Introduction to Barlow's Mathematical Tables.

### General Properties of the Roots of Equations.

1. Every equation of the general form

$$x^m + A x^{m-1} + B x^{m-2} + C x^{m-3} + \&c. + K = 0$$

has  $m$  roots real or imaginary (see IMAGINARY ROOTS); and may be supposed to be formed by the continued product of  $m$  factors,

$$(x - \alpha) (x - \beta) (x - \gamma) (x - \delta) \&c. = 0,$$

where  $\alpha, \beta, \gamma, \delta, \&c.$  are the roots of the equation.

2. The imaginary roots of an equation always enter in pairs, and if  $a + b\sqrt{-1}$  be one of those roots,  $a - b\sqrt{-1}$  is another of them; so that the sum of every pair of them is a real quantity, and the square of their difference a real negative quantity; and an equation can have no imaginary root but is reducible to the above form. These properties of the imaginary roots of equation are generally attributed to d'Alembert.

3. Since every equation

$$x^m + Ax^{m-1} + Bx^{m-2} + Cx^{m-3} + \&c. + K = 0$$

is composed of the factors

$$(x - \alpha) (x - \beta) (x - \gamma) (x - \delta) \&c. = 0,$$

it is obvious, that if, by any means, one of those roots, as  $\alpha$ , can be found, the original equation may be divided by  $(x - \alpha)$ , and thence be reduced to another of lower dimensions.

4. If we suppose the signs of each of the roots of an equation to be changed, then the co-efficient of the second term of that equation will be equal to the sum of all those roots so changed; the co-efficient of the third term equal to the sum of all the products that can be formed with them, taken two and two at a time; the co-efficient of the fourth term equal to all the products that can be formed with them, taken three and three at a time; and so on to the absolute term, which is equal to the product of all the roots; thus, if  $a, b, c, d$ , be the roots of an equation, then the co-efficient of the first term being 1, that of the

$$\begin{aligned} 2d &= -(a + b + c + d) \\ 3d &= (ab + ac + ad + bc + bd + cd) \\ 4th &= -(abc + abd + acd + bcd) \\ 5th &= abcd \end{aligned}$$

5. If the substitution of any two numbers,  $m$  and  $n$ , instead of the unknown quantity of an equation, give results with contrary signs, one, or some odd number, of the real roots of the equation, are contained between those two limits.

6. And conversely, if two numbers be substituted for the unknown quantity of an equation, which comprise between them any odd number of the roots of that equation, the results thus obtained must necessarily have contrary signs. But if two, or any even number of roots, be comprised between those limits, then no change of signs will take place in the results. See a demonstration of these properties in Barlow's Tables.

7. Therefore, when we substitute for the unknown quantity of an equation the several terms of the progression, 0, 1, 2, 3, &c. it will furnish us with the integral limits of all the real positive roots of that equation, provided it has not any that differ from each other by a quantity less than unity, or if it have any odd number of such roots; but if two, or any even number of its roots, be comprised between two consecutive integers, then these substitutions will not enable us (at least not by the change of sign) to discover the integral limits between which they are comprised.

8. But if we substitute for the unknown quantity the several terms of the progression, 0,  $\Delta$ , 2  $\Delta$ , 3  $\Delta$ , &c.  $\Delta$  being supposed less than the difference of any two of the real roots of the equation, then the limits of every real positive root will be indicated by the several changes of signs in the respective results.

The above two properties have chiefly reference to Lagrange's method of approximation.

9. If, in an equation, whatever real value be substituted for the unknown quantity, the result is always positive, it is certain that all the roots of that equation are imaginary.

10. The signs of all the roots of an equation may be changed from positive to negative, or from negative to positive, by changing the signs of the alternate co-efficients, viz. the 2d, 4th, 6th, &c.; and hence the finding the real roots of an equation is reduced to that of finding positive roots only.

11. Every equation of an odd degree has at least one real root, which will be positive if the last term be negative, or negative if that term be positive.

12. Every equation of even dimensions, having its last term negative, has at least two real roots, one positive and the other negative; but if its last term be positive, it furnishes us with no means of judging of the nature of the roots.

13. The first term of an equation having (as we have supposed throughout) unity for its co-efficient, its greatest positive root will be less than the greatest negative co-efficient plus 1.

14. And the absolute term of an equation being divided by the sum of that term, and the greatest co-efficient having a contrary sign, will give a limit less than the least root of that equation.

15. An equation, having unity for the co-efficient of its first term, and integral co-efficients for all its others, cannot have a fractional root, viz. its roots must be either integral, irrational, or imaginary.

16. An equation cannot have more real positive roots, than there are variations in the succession of the signs of its co-efficients, nor more real negative roots than there are permanencies of signs.

Therefore, when all the roots of an equation are real, there are precisely as many positive roots as there are variations, and as many negative roots as there are permanencies.

17. When any term of an equation is wanting, or has its co-efficient equal to zero, and the preceding and following terms have the same signs, the equation has necessarily some imaginary roots.

18. An equation cannot have all its roots comprised between two consecutive integers, nor between any two integers, of which the difference is not greater than 2.

These properties, the demonstrations of which are given by different algebraical authors, may frequently be advantageously consulted in determining the nature and limits of the roots of equations.

*On the Forms of the Roots of Equations.*—We have before observed, that the roots of equations, beyond those of the fourth degree, cannot be generally exhibited in an analytical form; yet from the analogy discoverable in those of inferior dimensions, there seems little doubt but that those of the fifth and higher dimensions partake of the same form.

When an equation of the second, third, or fourth degree has its second term taken away, to reduce it to its most convenient form for solution, the roots will have the following form.

*Second Degree.*

$$x = a \sqrt{p}, x = a' \sqrt{p}, \text{ where } a, a', \text{ are the roots of 1.}$$

*Third Degree.*

$$x = \sqrt[3]{p^3 + \sqrt[3]{q}}, x = a' \sqrt[3]{p} + a \sqrt[3]{q}, x = a^2 \sqrt[3]{p} + a \sqrt[3]{q}, \text{ where } a \text{ and } a' \text{ are the two imaginary roots of } \sqrt[3]{1}.$$

*Fourth Degree.*

$$\left. \begin{aligned} x &= \sqrt[4]{p} + \sqrt[4]{q} + \sqrt[4]{r} \\ x &= a \sqrt[4]{p} + a^2 \sqrt[4]{q} + a^3 \sqrt[4]{r} \\ x &= a^2 \sqrt[4]{p} + a^3 \sqrt[4]{q} + a \sqrt[4]{r} \\ x &= a^3 \sqrt[4]{p} + a \sqrt[4]{q} + a^2 \sqrt[4]{r} \end{aligned} \right\} \text{ where } a, a^2, a^3, \text{ are the three imaginary roots of } \sqrt[4]{1}.$$

Whence

Whence it is very natural to infer, that in an equation of the fifth degree, the roots will have the form,

$$\begin{aligned} x &= \sqrt[5]{p} + \sqrt[5]{q} + \sqrt[5]{r} + \sqrt[5]{s} \\ x &= a \sqrt[5]{p} + a^2 \sqrt[5]{q} + a^3 \sqrt[5]{r} + a^4 \sqrt[5]{s} \\ x &= a^2 \sqrt[5]{p} + a^4 \sqrt[5]{q} + a \sqrt[5]{r} + a^3 \sqrt[5]{s} \\ x &= a^3 \sqrt[5]{p} + a \sqrt[5]{q} + a^4 \sqrt[5]{r} + a^2 \sqrt[5]{s} \\ x &= a^4 \sqrt[5]{p} + a^3 \sqrt[5]{q} + a^2 \sqrt[5]{r} + a \sqrt[5]{s} \end{aligned}$$

where  $a, a^2, a^3, a^4$ , are the four imaginary roots of  $\sqrt[5]{1}$ .

This generalization of the forms of the roots of equations, though generally attributed to Euler, is, we believe, due to Waring; but neither of these able analysts were able to derive from it the solution of any general equation above the fourth degree. On the subject of equations, *viz.* of finding their roots, we would refer the reader to Waring's "Meditationes Algebraicæ," Lea's "Resolution of the higher Equations in Algebra," La Grange's treatise on the resolution "Des Equations Numeriques," and the Introduction to Barlow's "Mathematical Tables," from which we have extracted the following general synopsis of resolution. See also Bonnycastle's Algebra.

*General Synopsis of the direct and approximate Methods of ascertaining the Roots of Numbers and Equations.*

*Extraction of the Roots of Numbers.*

- I. Let  $n$  represent the index of the root,
- $x$  the number of which the root is required,
- $r$  an approximate value of  $\sqrt[n]{x}$ ;

which may be found by trial, or otherwise, as near as convenient, and either in excess or defect: then will,

$$1. \sqrt[n]{x} = r + \frac{2r(x - r^n)}{(n+1)r^n + (n-1)x} \text{ very nearly.}$$

And using this new approximate value in the same way, another value may be found still nearer; and so on, to any degree of accuracy required.

This general formula resolves itself into the following particular ones; *viz.*

2.  $\sqrt{x} = r + \frac{2r(x - r^2)}{3r^2 + x}$ .
3.  $\sqrt[3]{x} = r + \frac{r(x - r^3)}{2r^2 + x}$ .
4.  $\sqrt[4]{x} = r + \frac{2r(x - r^4)}{5r^3 + 3x}$ .
5.  $\sqrt[5]{x} = r + \frac{r(x - r^5)}{3r^4 + 2x}$ .
6.  $\sqrt[6]{x} = r + \frac{2r(x - r^6)}{7r^5 + 5x}$ .
7.  $\sqrt[7]{x} = r + \frac{r(x - r^7)}{4r^6 + 3x}$ .
- &c. &c.

*By the Binomial Theorem.*

II. Let  $(a + b)$  represent any binomial, and  $n$  the index of the root or power, which may be either positive or negative, integral or fractional; then will

$$(a + b)^n =$$

$$(1) a^n + \frac{n}{1} a^{n-1} b + \frac{n(n-1)}{1 \cdot 2} a^{n-2} b^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} a^{n-3} b^3 + \&c.$$

If  $b$  be negative, the odd powers of  $b$  will also be negative; that is,

$$(2) a^n - \frac{n}{1} a^{n-1} b + \frac{n(n-1)}{1 \cdot 2} a^{n-2} b^2 - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} a^{n-3} b^3 + \&c.$$

Otherwise: let  $\frac{m}{n}$  represent the index, and put  $\frac{b}{a} = Q$ ; also, let A, B, C, D, &c. represent the first, second, third, &c. terms of the series, with their proper signs; then will

$$(3) (a + b)^{\frac{m}{n}} = (a + aQ)^{\frac{m}{n}} = \begin{matrix} A & B & C & D \\ (3) a^{\frac{m}{n}} + \frac{m}{n} A Q + \frac{m-m}{2n} B Q + \frac{m-2n}{3n} C Q \\ + \frac{m-3n}{4n} D Q + \&c.; \end{matrix}$$

which is by far the most convenient form in the case of fractional or negative indices.

ROOTS OF EQUATIONS.

QUADRATIC EQUATIONS.

III. Let  $x^2 + ax - b = 0$ , or  $x^2 + ax = b$ , represent any quadratic equation,  $a$  and  $b$  being either positive or negative; then will

$$x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}.$$

But if  $a$  and  $b$ , independent of the sign by which they are preceded, be always supposed positive; then this general formula resolves itself into the four following particular ones; *viz.*

1.  $x^2 + ax - b = 0$ , where  $x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}$ .
2.  $x^2 - ax - b = 0$ , where  $x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}$ .
3.  $x^2 - ax + b = 0$ , where  $x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)}$ .
4.  $x^2 + ax + b = 0$ , where  $x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)}$ .

*By Sines and Tangents.*

IV.

$$\begin{aligned} 1. x^2 + px &= q. \\ \text{Put } \frac{2}{p} \sqrt{q} &= \tan. z; \text{ then} \\ x &= \begin{cases} + \sqrt{q} \times \tan. \frac{1}{2} z, \text{ or} \\ - \sqrt{q} \times \cot. \frac{1}{2} z. \end{cases} \end{aligned}$$

2.  $x^2 + px = q.$

Put  $\frac{2}{p} \sqrt{q} = \tan. z$ ; then  
 $x = \begin{cases} + \sqrt{q} \times \text{cof. } z, \text{ or} \\ - \sqrt{q} \times \tan. z. \end{cases}$

3.  $x^2 + px = -q.$

Put  $\frac{2}{p} \sqrt{q} = \sin. z$ ; then  
 $x = \begin{cases} - \sqrt{q} \times \tan. \frac{1}{2} z, \text{ or} \\ - \sqrt{q} \times \text{cof. } \frac{1}{2} z. \end{cases}$

4.  $x^2 - px = -q.$

Put  $\frac{2}{p} \sqrt{q} = \sin. z$ ; then  
 $x = \begin{cases} + \sqrt{q} \times \tan. \frac{1}{2} z, \text{ or} \\ + \sqrt{q} \times \text{cof. } \frac{1}{2} z. \end{cases}$

CUBIC EQUATIONS.

By Cardan's Rule.

V. Let  $x^3 + ax - b = 0$ , or  $x^3 + ax = b$ , represent any cubic equation wanting its second term, and in which  $a$  and  $b$  may be either positive or negative; then will

1.  $x = \sqrt[3]{\left\{\frac{b}{2} + \sqrt{\left(\frac{b^2}{4} + \frac{a^3}{27}\right)}\right\}} + \sqrt[3]{\left\{\frac{b}{2} - \sqrt{\left(\frac{b^2}{4} + \frac{a^3}{27}\right)}\right\}}.$

2.  $x = \sqrt[3]{\left\{\frac{b}{2} + \sqrt{\left(\frac{b^2}{4} + \frac{a^3}{27}\right)}\right\}} - \frac{\frac{1}{3} a}{\sqrt[3]{\left\{\frac{b}{2} + \sqrt{\left(\frac{b^2}{4} + \frac{a^3}{27}\right)}\right\}}}.$

Which latter form is frequently the most convenient, as it requires only one extraction of the cube root, whereas the former requires two.

The second term of a cubic equation may be taken away by the following formulæ:

Let  $y^3 + py^2 + qy + r = 0.$

Affume  $y = \frac{x-p}{3}$ ;  $a = 9q - 3p^2$ ; and  $b = 9pq - 2p^3 - 27r$ ;

so shall  $x^3 + ax - b = 0$  be the transformed equation required, which will, under this form, have integral coefficients.

When  $a$  is negative, that is, when the equation is  $x^3 - ax = b$ , the preceding formula becomes

3.  $x = \sqrt[3]{\left\{\frac{b}{2} + \sqrt{\left(\frac{b^2}{4} - \frac{a^3}{27}\right)}\right\}} + \sqrt[3]{\left\{\frac{b}{2} - \sqrt{\left(\frac{b^2}{4} - \frac{a^3}{27}\right)}\right\}}.$

And here, when  $\frac{a^3}{27} > \frac{b^2}{4}$ , both branches of the root become imaginary, and the equation is said to be of the irreducible case; no solution being then obtainable by this rule, except in those cases in which the cube root of each of

these branches can be found in other binomial surds, which, when possible, is done by the following formulæ:

(1)  $\sqrt[3]{(a \pm \sqrt{b})} = x + \sqrt{y}.$   
 (2)  $x^3 - \frac{3}{2} x \sqrt[3]{(a^2 - b)} - \frac{1}{2} a = 0.$   
 (3)  $y = x^2 - \sqrt[3]{(a^2 - b)}.$

By Sines and Tangents.

VI. In this case, it is necessary to separate the above general formula into the following particular ones, according as  $a$  and  $b$  are positive or negative, as follows; viz.

Form 1.  $x^3 + ax - b = 0.$   
 2.  $x^3 + ax + b = 0.$   
 3.  $x^3 - ax - b = 0.$   
 4.  $x^3 - ax + b = 0.$

1. Solution of Form 1:  $x^3 + ax - b = 0.$

Put  $\frac{b}{2} \left(\frac{3}{a}\right)^{\frac{2}{3}} = \tan. z$ ; and  $\sqrt[3]{\tan. (45^\circ - \frac{1}{2} z)} = \tan. u.$

Then  $x = 2 \sqrt{\frac{a}{3}} \times \cot. 2u.$

2. Solution of Form 2:  $x^3 + ax + b = 0.$

Put  $\frac{b}{2} \left(\frac{3}{a}\right)^{\frac{2}{3}} = \tan. z$ ; and  $\sqrt[3]{\tan. (45^\circ - \frac{1}{2} z)} = \tan. u.$

Then will  $x = -2 \sqrt{\frac{a}{3}} \times \cot. 2u.$

3. Solution of Form 3:  $x^3 - ax - b = 0.$

This form resolves itself into two cases, according as  $\frac{2}{b} \left(\frac{a}{3}\right)^{\frac{2}{3}}$  is less or greater than 1.

In the first case, put  $\frac{2}{b} \left(\frac{a}{3}\right)^{\frac{2}{3}} = \text{cof. } z$ , and  $\sqrt[3]{\tan. (45^\circ - \frac{1}{2} z)} = \tan. u.$

Then will  $x = 2 \sqrt{\frac{a}{3}} \times \text{cofec. } 2u.$

In the second case, put  $\frac{b}{2} \left(\frac{3}{a}\right)^{\frac{2}{3}} = \text{cof. } z$ , then has  $x$  the three following values, viz.

1.  $x = 2 \sqrt{\frac{a}{3}} \times \text{cof. } \frac{z}{3}.$   
 2.  $x = -2 \sqrt{\frac{a}{3}} \times \text{cof. } \left(60^\circ + \frac{z}{3}\right).$   
 3.  $x = -2 \sqrt{\frac{a}{3}} \times \text{cof. } \left(60^\circ - \frac{z}{3}\right).$

4. Solution of Form 4:  $x^3 - ax + b = 0.$

This has also two cases, according as  $\frac{2}{b} \left(\frac{a}{3}\right)^{\frac{2}{3}}$  is less or greater than 1.

In the first case, put  $\frac{2}{b} \left(\frac{a}{3}\right)^{\frac{2}{3}} = \text{cof. } z$ , and  $\sqrt[3]{\tan. (45^\circ - \frac{1}{2} z)} = \tan. u.$

Then will  $x = -2 \sqrt{\frac{a}{3}} \times \text{cof. } 2u.$

# ROOT.

In the second case, put  $\frac{b}{2} \left(\frac{3}{a}\right)^{\frac{1}{3}} = \text{cof. } z$ , then has  $x$  the three following values:

1.  $x = -2 \sqrt{\frac{a}{3}} \times \text{cof. } \frac{z}{3}$ .
2.  $x = 2 \sqrt{\frac{a}{3}} \times \text{cof. } \left(60^\circ + \frac{z}{3}\right)$ .
3.  $x = 2 \sqrt{\frac{a}{3}} \times \text{cof. } \left(60^\circ - \frac{z}{3}\right)$ .

The two latter cases of forms 3 and 4 belong to the irreducible case, each of which gives three real roots or values of  $x$ ; whereas the other forms have each only one real root. See *IRREDUCIBLE CASE*.

### By infinite Series.

Let  $x^3 + ax = b$  represent any cubic equation, in which  $a$  and  $b$  may be each either positive or negative.

Assume  $\frac{2b}{\sqrt[3]{2(27b^2 + 4a^3)}} = \varphi$ , and  $\frac{27b^{\frac{1}{3}}}{27b^2 + 4a^3} = \pi$ ; then,

$$1. \begin{cases} x = \varphi \times \left[1 + \frac{2.5}{6.9} \pi + \frac{2.5 \cdot 8 \cdot 11}{6.9 \cdot 12 \cdot 15} \pi^2 + \frac{2.5 \dots 17}{6.9 \dots 21} \pi^3 + \&c.\right], \text{ or} \\ x = \varphi \times \left[1 + \frac{2.5}{6.9} \pi A + \frac{8 \cdot 11}{12 \cdot 15} \pi B + \frac{14 \cdot 17}{18 \cdot 21} \pi C + \&c.\right] \end{cases}$$

In which last form, A, B, C, &c. represent the preceding terms.

Again, assume  $2 \sqrt{\frac{b}{2}} = \varphi$ , and  $\frac{27b^{\frac{1}{3}} + 4a^3}{27b^{\frac{1}{3}}} = \pi$ ; then,

$$2. \begin{cases} x = \varphi \times \left[1 - \frac{2}{3.6} \pi - \frac{2.5 \cdot 8}{3.6 \cdot 9 \cdot 12} \pi^2 - \frac{2.5 \dots 14}{3.6 \dots 18} \pi^3 - \&c.\right], \text{ or} \\ x = \varphi \times \left[1 - \frac{2}{3.6} \pi A - \frac{5 \cdot 8}{9 \cdot 12} \pi B - \frac{11 \cdot 14}{15 \cdot 18} \pi C - \&c.\right] \end{cases}$$

In which, also, A, B, C, &c. are the preceding terms.

Both these series are correct analytical expressions for the value of  $x$ , in the general cubic equation  $x^3 + ax = b$ ; but they are not equally commodious for the purposes of solution.

The former must be used in all cases when  $a$  is positive, as also when  $a$  is negative, and  $4a$  greater than  $54b^{\frac{2}{3}}$ ; and the latter when  $a$  is negative, and  $4a$  less than  $54b^{\frac{2}{3}}$ ; because then  $\pi$ , in both cases, will be less than unity, and the series will, therefore, be converging ones.

### BIQUADRATIC EQUATIONS.

#### By Simpson's Rule.

VIII. Let  $x^4 + ax^3 + bx^2 + cx + d = 0$ , be any equation of the fourth degree, in which  $a, b, c, d$ , may be any numbers at pleasure, positive, negative, or zero.

Find the values of  $p, q$ , and  $r$ , by means of the three equations

$$\begin{aligned} 8p^3 - 4bp^2 + (2ac - 8d)p - a^2d + 4bd - c^2 &= 0 \\ q &= \sqrt{\left(\frac{1}{4}a^2 + 2p - b\right)} \\ r &= \frac{ap - c}{2q}; \end{aligned}$$

then will the four roots of the proposed equation be contained in the following formulæ;

$$\begin{aligned} x &= -\frac{\frac{1}{2}a - q}{2} \pm \sqrt{\left\{\left(\frac{\frac{1}{2}a - q}{2}\right)^2 + r - p\right\}} \\ x &= -\frac{\frac{1}{2}a + q}{2} \pm \sqrt{\left\{\left(\frac{\frac{1}{2}a + q}{2}\right)^2 - r - p\right\}} \end{aligned}$$

The above rule was only generalized by Simpson, it is originally due to Ferrari, though commonly ascribed to Bombelli.

#### By Descartes' Rule.

IX. Let  $x^4 + ax^2 + bx + c = 0$ , be any biquadratic equation, wanting its second term.

Find the value of  $y$  in the double cubic equation

$$y^3 + 2ay^2 + (a^2 - 4c)y^2 - b^2 = 0;$$

then will the four values of  $x$  be comprised in the formulæ

$$\begin{aligned} x &= \frac{1}{2}y \pm \sqrt{\left(-\frac{1}{4}y^2 - \frac{1}{2}a - \frac{b}{2y}\right)} \\ x &= \frac{1}{2}y \pm \sqrt{\left(-\frac{1}{4}y^2 - \frac{1}{2}a + \frac{b}{2y}\right)} \end{aligned}$$

#### By Euler's Rule.

X. Let  $x^4 - ax^2 - bx - c = 0$ , be any biquadratic equation, wanting its second term,  $a, b$ , and  $c$ , being any numbers, positive, negative, or zero.

$$\text{Assume } f = \frac{1}{2}a; \quad b = \frac{b^2}{64}; \quad g = \frac{1}{16}a^2 + \frac{1}{4}c.$$

Then find the three roots of the cubic equation

$$y^3 + fy^2 + gy - b = 0,$$

which let be  $p, q$ , and  $r$ .

Then will the four values of  $x$  in the original equation be expressed as follows.

When  $b$  is positive,

$$\begin{aligned} 1^{\text{st}} \text{ root } x &= \sqrt{p} + \sqrt{q} + \sqrt{r} \\ 2^{\text{d}} \text{ } x &= \sqrt{p} - \sqrt{q} + \sqrt{r} \\ 3^{\text{d}} \text{ } x &= -\sqrt{p} + \sqrt{q} - \sqrt{r} \\ 4^{\text{th}} \text{ } x &= -\sqrt{p} - \sqrt{q} + \sqrt{r} \end{aligned}$$

When  $b$  is negative,

$$\begin{aligned} 1^{\text{st}} \text{ root } x &= \sqrt{p} + \sqrt{q} - \sqrt{r} \\ 2^{\text{d}} \text{ } x &= \sqrt{p} - \sqrt{q} + \sqrt{r} \\ 3^{\text{d}} \text{ } x &= -\sqrt{p} + \sqrt{q} + \sqrt{r} \\ 4^{\text{th}} \text{ } x &= -\sqrt{p} - \sqrt{q} - \sqrt{r} \end{aligned}$$

### EQUATIONS IN GENERAL.

#### By Approximation.—First Method.

XI. Let  $x^n + ax^{n-1} + bx^{n-2} + cx^{n-3} + dx^{n-4} + \&c. = 0$ , be any general equation, in which  $a, b, c, d, \&c.$  are any numbers, positive, negative, or zero; then  $r$  being an approximate value of  $x$ , we have

# ROOT.

$$1. x = \frac{(n-1)r^n + (n-2)ar^{n-1} + (n-3)br^{n-2} + (n-4)cr^{n-3} + \&c}{nr^{n-1} + (n-1)ar^{n-2} + (n-2)br^{n-3} + (n-3)cr^{n-4} + \&c.}$$

nearly, which general form resolves itself into the following particular ones; viz.

*Equations of the third Degree.*

$$2. x^3 + ax^2 + bx + c = 0;$$

$$x = \frac{2r^3 + ar^2 - c}{3r^2 + 2ar + b}$$

*Equations of the fourth Degree.*

$$3. x^4 + ax^3 + bx^2 + cx + d = 0;$$

$$x = \frac{3r^4 + 2ar^3 + br^2 - d}{4r^3 + 3ar^2 + 2br + c}$$

*Equations of the fifth Degree.*

$$4. x^5 + ax^4 + bx^3 + cx^2 + dx + e = 0;$$

$$5. x = \frac{4r^5 + 3ar^4 + 2br^3 + cr^2 - e}{5r^4 + 4ar^3 + 3br^2 + 2cr + d}$$

&c. &c.

*By the second Method.*

XII. Let  $x^n + ax^{n-1} + bx^{n-2} + cx^{n-3} + dx^{n-4} + \&c. = w$ , be any general equation, as before, and  $r$  an approximate value of  $x$ ; then making

$r^n + ar^{n-1} + br^{n-2} + cr^{n-3} + dr^{n-4} + \&c. = v$   
we shall have

$$1. x = r + \frac{(w-v)2r}{(n-1)w + (n+1)r^n + (n-1)ar^{n-1} + (n-3)br^{n-2} + \&c.}$$

Or,

$$2. x = r + \frac{(w-v)2r}{(n-1)v + (n+1)r^n + (n-1)ar^{n-1} + (n-3)br^{n-2} + \&c.}$$

The first formula being applicable to the case in which  $r$  is greater than unity, and the second to those in which it is less.

These general formulæ resolve themselves into the following particular ones; viz.

*Equations of the third Degree.*

$$3. x^3 + ax^2 + bx + c = w;$$

$$x = r + \frac{(w-v)r}{w \text{ or } v + 2r^2 + ar}$$

*Equations of the fourth Degree.*

$$4. x^4 + ax^3 + bx^2 + cx + d = w;$$

$$x = r + \frac{(w-v)2r}{3w \text{ or } 3v + 5r^3 + 3ar^2 + br - cr}$$

*Equations of the fifth Degree.*

$$5. x^5 + ax^4 + bx^3 + cx^2 + dx + e = w;$$

$$x = r + \frac{(w-v)r}{2w \text{ or } 2v + 3r^4 + 2ar^3 + br - dr}$$

The latter formulæ, which are by far the most converging, were first published by Mr. Barlow, in No. 12. of *Leybourn's Mathematical Repository*; with reference to which we propose giving one example by way of illustration.

*Example.*—Given  $x^3 - 2x = 5$ .

Assume  $r = 2$ , then (by formula 1),

$$\begin{array}{r} r^3 = 8 \\ - 2r = -4 \\ \hline v = 4 \end{array} \qquad \begin{array}{r} 2r^3 = 16 \\ w = 5 \end{array}$$

$$\begin{array}{r} v = 4 \\ w = 5 \\ \hline w - v = 1 \\ r = 2 \end{array}$$

21 divisor.

$$\text{whence } \frac{1 \times 2}{21} = .094.$$

Therefore  $x = 2.094$  nearly.

Assume, therefore,  $r = 2.094$ , then,

$$\begin{array}{r} r^3 = 9.181846584 \\ - 2r = 4.188 \\ \hline v = 4.993846584 \\ w = 5. \end{array} \qquad \begin{array}{r} 2r^3 = 18.363693168 \\ w = 5 \\ \hline 23.363693168 \end{array}$$

$$\begin{array}{r} w - v = .006153416 \\ r = 2.094 \end{array}$$

$$r(w-v) = .012885253$$

$$\text{whence } \frac{.012885253}{23.3636931} = .0005515.$$

Therefore  $x = .0945515$  nearly; which is true to the nearest figure in the eighth place, by only two substitutions.

ROOT, *Falſe*. See FALSE.

ROOT, *Impossible*, is not only the ſquare root of a negative quantity, but any other root denominated by any even number. Thus  $\sqrt[4]{-1}$ ,  $\sqrt[6]{-1}$ ,  $\sqrt[8]{-1}$ , or in

general  $\sqrt[2m]{-1}$ ,  $\sqrt[2m]{-x}$ , are all *impoſſible* roots, or quantities. Some call them imaginary roots or quantities. See FALSE Root.

ROOT, *Real*. See FALSE Root.

ROOT, *Reſidual*. See RESIDUAL.

ROOTS of Equations, *Extraction of the*. See EXTRACTION, REDUCTION of Equations, and ROOT of an Equation, *ſupra*.

ROOTS, *Radices*, in Grammar, are the primitive words of a language, whence others are compounded or derived.

Thus the Latin *fluo* is the root of *fluens*, *fluxio*, *flumen*, *fluvialis*, *influxus*, *reſtuens*, *fluſifer*, *fluſiſonus*, *fluſivagus*, &c. Thus alſo the Greek  $\rho\omicron\omicron\varsigma$  is the root of  $\rho\omicron\iota\omicron\varsigma$ ,  $\epsilon\upsilon\iota\omicron\varsigma$ ,  $\epsilon\theta\epsilon\tau\iota\text{-}\alpha\sigma\mu\omicron\varsigma$ , &c.

And thus alſo, though in a leſs proper ſenſe, the Daniſh *rood* is the root of the Engliſh word *root*; the Latin *radix* the root of the French *racine*, as *rado* is the root of *radix*; and perhaps  $\rho\alpha\delta\iota\omicron\varsigma$  the root of *rado*.

Roots, in the Hebrew language, conſiſt of thoſe letters that are denominated *radical* (which ſee), and are generally verbs, conſiſting commonly of three, ſometimes of two, and rarely of four letters. Of whatever letters, whether radical or ſervile, any word conſiſts, it muſt, at leaſt, contain one of a radical character. The inveſtigation of the radical and a primitive is an object of importance in grammar. In order to facilitate their inveſtigation in the Hebrew, and other Eaſtern languages, it is neceſſary to be well acquainted with the diviſion of the letters into *radical* and *ſervile* (ſee each term), becauſe theſe laſt muſt be rejected before the root is obtained.

If the root conſiſt of pure radicals, commonly *three* in number, it is eaſily found, and as eaſily diveſted of the ſerviles which attend it. But, as the ſervile letters may alſo conſtitute roots, it is ſometimes a matter of difficulty to diſtinguiſh when theſe letters ought to be conſidered in their *radical*, and when in their *ſervile* capacity. This difficulty is increaſed in the verbs denominated *imperfect*. For, in ſome of their parts, either by contraction, or commutation, theſe verbs loſe ſometimes one, ſometimes two, of their radical letters, which muſt be reſtored to their place before the root can be exhibited in its true form.

The learner muſt therefore endeavour, by frequent practice, to acquire a dexterity in diſcovering the radical letters, in diveſting them of their ſerviles, and in reſtoring them where they are loſt by the abbreviated flexions. This exerciſe is the more neceſſary, as, in almoſt all lexicons, the words are arranged according to the alphabetical order of the roots. Theſe are commonly printed in a larger character, and have below them their derivatives, as children and deſcendants. By this plan, neither the ſignification of any verb, nor of any noun derived from it, can be found, till its root be inveſtigated and determined.

The following directions will be found uſeful in the inveſtigation of radical words.

The chief things to be attended to are, what letters are commonly ſervile, either in nouns or verbs; in what part of the word they moſt generally appear; and what is the moſt probable conjecture to be formed, in order to reſtore theſe radicals as are loſt by the abbreviated flexions.

The ſervile letters in nouns are ſuch as form the feminine gender, and the plural terminations, the prefixes, including

the ſigns of the caſes, the hecmanic letters, and the poſſeſſive pronouns, or affixes.

The ſervile letters in verbs are the perſonal prefixes and poſtfixes, formerly named the *pronominal ſerviles*, the characteristics of the different forms, and the verbal affixes.

γ and ϑ whether inſerted in nouns or verbs, muſt be rejected in the inveſtigation of the root.

As the ſerviles generally appear in greateſt number at the end of words, the moſt proper method of diſcovering the root ſeems to be this:

Begin from the left hand, remove the ſerviles as you go along, retain the pure and the ſuppoſed radicals, reject the inſerted γ and ϑ, reſtore or commute the radicals loſt by abbreviations, and, finally, reject the prefixes.

*Directions for finding the Root, and for reſtoring the deficient Radicals.*

I. If, after rejecting the ſerviles, three pure radicals remain, you may conclude theſe to be the root.

II. If only two remain, as is the common caſe in abbreviated roots, prefix to theſe either ϑ or ϑ or inſert γ betwixt them, or poſtpone ϑ or double the ſecond.

The inveſtigation of roots is not peculiar to the Hebrew, but common to all languages, and is of ſingular advantage, if we would attend to accuracy and propriety of writing.

In ſuch languages as do not admit of the diſtinction between radical and ſervile letters, the following may be obſerved as general rules for reducing words to their firſt principles. Let that part of the word which remains unvaried be conſidered as the radical term, and let the changes of termination be diſregarded, or cut off. Compound words muſt be reſolved into their component parts, and the prepoſitions excluded. In thoſe words which ſeem reducible to Hebrew roots conſiſting entirely of conſonants, the intermediate vowels employed for their enunciation, are not to be conſidered as eſſential, or as conſtituting a part of the root. See Wilſon's Elements of Hebrew Grammar. Maſcleſ Gram. Heb. vol. i. c. 21. p. 214, &c. Robertſon's Gram. Heb. Appendix, iii.

The Greek and Hebrew tongues are learnt by roots. Of dictionaries, ſome are in alphabetical order, others are diſpoſed by roots, as Scapula, Faber's Theſaurus, and the firſt edition of the Dictionary of the French Academy. In the edition of 1718, this laſt is thrown into the uſual alphabetical order.

ROOTS, in *Geography*, a town of Virginia, in the Mattapony; four miles N.E. of Weſt Point.

ROOTS, a townſhip of Portage county, in the Ohio, containing 216 inhabitants.

ROOTWELT, in *Huſbandry*, a term applied to the hats of grain, when the butt-ends of the ſheaves are turned up towards the wind and ſun, in order to dry them. The practice is common in bad rainy harveſts. See HARVEST, and HARVESTING Grain.

ROPALON, in *Botany*, a name given by ſome authors to the *nymphaea*, or water-lily, and alſo to the *ſaba Aegyptia* of the river Nile.

ROPE, an aſſemblage of ſeveral twiſts or ſtrings of hemp, twiſted together by means of a wheel; of various uſes, as in binding, ſlaying, drawing, ſuſpending, &c.; or, all cordage, in general, above one inch in circumference, moſtly made of hemp ſpun into yarns or threads of a certain length; and a number of theſe yarns or threads, according to the ſize of the rope, are twiſted together, and called a ſtrand. Three of theſe ſtrands twiſted or laid together, is called a hawſer-laid rope, and nine of them a cable-laid rope. See ROPE-Making.

When the rope is made very thick, it is called a *cable*; and when very small, a *cord*.

Though it be difficult to give a certain account of the forces required to bend ropes of different diameters, in making them go round bodies of different bignesses, yet to make no allowance for the loss of motion sustained thereby, would be as prejudicial to the practice of mechanics, as it would be to overlook the friction of the parts of engines. The difficulty of ascertaining this force arises from the different materials of which they are made, their different stiffness according as they are more or less twisted; and sometimes from the temperature of the air, as to moisture and dryness.

Dr. Defaguliers has computed the forces required to bend ropes of different diameters, stretched by different weights, round rollers of different bignesses. The result of his experiment is expressed in the following table.

Diameters of the ropes of three strands, expressed in tenth parts of an inch.	Weights stretching the ropes, expressed in lb. avoirdupois.	Resistance about a roller of half an inch diameter, in oz. avoirdupois.	Resistance about a roller of one inch diameter, in oz. avoirdupois.	Resistance about a roller of one and a half inch diameter, in oz. avoirdupois.
0.5	60	225	112½	75
0.2	60	90	45	30
0.1	60	45	22½	15
0.5	40	150	75	50
0.2	40	60	30	20
0.1	40	30	15	10
0.5	20	75	37½	25
0.2	20	30	15	10
0.1	20	15	7½	*

On the whole, it has been found by experiments, that the difficulty of bending a rope round a roller decreases directly as the diameter of the roller increases, or is, inversely, as the diameter of the roller. See Defaguliers, *Experim. Phil.* vol. i. p. 233, &c. See also *CORDAGE*.

A TABLE, shewing how many fathoms, feet, and inches of a rope of any size, under fourteen inches, makes a hundred weight, with the use of the table.

Inches.	Fathoms.	Feet.	Inches.	Fathoms.	Feet.	Inches.	Fathoms.	Feet.	Inches.	Fathoms.	Feet.	Inches.

7	10 1	11½	33 0	16	64 0	20½	105 0		

The greatest consumption of rope is used for the purposes of navigation in rigging of ships: where, though ropes include the whole cordage, there are several particularly denominated, and which have particular names given to them; as follow. 1. Awning-ropes are the ridge and side-ropes. The ridge-rope reeves through the trucks seized along the middle of the awning; the side-ropes reeve through the trucks seized along the side of the awning. By these ropes the awnings are spread between the masts. 2. Bell-rope, nine or ten feet in length, which splices round a thimble in the eye of the bell-crank. In the middle of the rope is a diamond-knot, and at the end a double wall-knot crowned. 3. Boat-rope, or painter, that by which the boat is towed at the stern; it splices with a thimble to a ring-bolt inside the stem. 4. Bolt-rope, the rope sewed to the edges of the sails, as the head-rope, foot-rope, and leech-rope. 5. Breast-rope, that fastened along the lanard of the shrouds, for safety, when heaving the lead in the chains. 6. Bucket-rope, that which is fastened to the bucket for hauling up water. 7. Buoy-rope, the one fastened to the buoy and crown of the anchor. 8. Davit-rope, the lashing which secures the davit to the shrouds when out of use. 9. Entering-ropes have their upper end thrust through the eye in the iron-stations at the gangways, and are walled and crowned; and diamond-knots are made at every nine inches asunder in the whole length. 10. Grapnel-rope, that which is bent to the grapnel, by which the boats ride. 11. Guit-rope, that fastened to an eye-bolt in the ship's side, and to the outer end of a boom projecting from the ship's side, by guys, to keep the boats clear from rubbing against the sides. 12. Heel-rope, that which hauls out the bowsprit of cutters, and the jib and fludding-sail boom. 13. Man-ropes are for the security of the men going out upon the bowsprit. 14. Parral-ropes are to connect the ribs and trucks of the parral together. 15. Passing-ropes lead round the ship through the eyes in the quarter waist and forecastle-stations, have one end stopped through the eye of the gangway-station, with a wall-knot crowned, and are set forward through an eye-bolt in the knight-head with a lanard, having a thimble turned into the end. 16. Ring-ropes are occasionally made fast to the ring or stopper-bolts in the deck, and by cross turns round the cable, to confine it more securely in stormy weather. 17. Slip-rope is to trice the bight of the cable into the heads;

## ROPE-MAKING.

heads; a slip-rope is also used in casting off a vessel, till got into the tide's way, &c. 18. Swab-rope is made fast to the eye of the swab, to raise it out of the water. 19. Tiller-ropes are the ropes by which the tiller is worked by means of the steering-wheel. 20. Top-rope is the rope that is reeved through the sheave-hole in the heel of the topmast, to raise it by its tackle to the mast-head. 21. Yard-ropes are only temporarily used to heave the yards on board.

Ropes are distinguished by being either *cable-laid* or *hawser-laid*: the former are composed of nine strands, viz. three great strands, each of which is composed of three smaller strands, and each containing an equal number of threads: and a rope, cable-laid, eight inches in circumference, has 333 threads, equally divided, and laid into nine strands: the latter is made with three strands, each of which contains a certain number of rope-yarns, in proportion to the size of the rope required. A rope hawser-laid, eight inches in circumference, has 414 threads, equally divided, and laid into three strands. Thirty fathoms of yarn make eighteen fathoms of rope cable-laid, and so in proportion. Thirty fathoms of yarn make twenty fathoms of rope hawser-laid, and so in proportion. Ropes of from one to two and a half inches in circumference are hawser-laid; of three inches to ten inches, either hawser-laid or cable-laid; and from ten inches to any greater dimension, always cable-laid.

Twice-laid cordage is made of cast rigging, as shrouds, stays, mooring and other cables, which, if not much worn, will make good ropes for netting ships' sides, worming and wooding for cables, spun-yarn for seizing, worming for large stays, seizing for drops of blocks, small cable-laid ropes for warping ships, ratlines, scaffolding-ropes for dock yards, &c.

When the yarn of this old stuff is overhauled, a little thin tar should be poured on it, which will make it pliable and lie better. The yarn unfit for knotting will pick into oakum for caulking.

To open a cable, for making it into small ropes, hang the strands upon three hooks in the tackle-board, stretch it out tight upon the hooks in the sledge, and heave till they are untwisted; then draw out the yarn.

The process of making small ropes is similar to making large ones, except the twisting and closing, which are done by a back-frame wheel or a table-wheel. See the next article.

*Rope-Making*, the art of preparing hemp, and spinning it into yarns or threads, and twisting those threads into strands, and laying those strands into cordage of the largest size, as the smallest kind is called *cord* or *twine* spinning.

Before we proceed further, it may be necessary to inform our readers of the different sorts of hemp proper to be made use of in the manufacturing of cordage. Of all the hems yet produced at our English markets, the Russian hemp has proved to be the best; it is grown in the southernmost parts of Russia, and shipped for England from the ports of St. Petersburg and Riga. The best sort is Riga rhine hemp: the next in quality is termed Petersburg clean hemp. These two are considered the best sorts of hemp to be used in making the strongest cordage.

The first process in the art of rope-making is, *Hatchelling the Hemp*.

Hatchelling the hemp, is the combing or clearing the ends, which else, in spinning, would run in with the long hemp, and so preparing it ready for the spinner; in the process of which, care and particular attention must be paid by the hatchellers that they do not use too great a quantity of oil, as in such case it will prevent the yarn from imbibing

its proper proportion of tar, and thereby prove a serious injury.

N. B. A small quantity of train-oil, say one pint to every hundred weight, sprinkled or daubed with a wad on the hemp, facilitates the hatcheller's business exceedingly, and is very necessary when the hemp is somewhat too dry, as the spinners are better able to perform their business when it has received such assistance.

The second and principal process to be attended to in the manufacturing of cordage, is *Spinning the Yarn*.

In spinning, particular attention must be paid by the spinner that the yarn be spun even, solid, and round; to accomplish which, he must spin with a strong even grip of the hand, taking care not to make his yarn larger in one place than in another, nor make a practice of spinning too much in a hurry; and the spinning-wheel must be kept turning a constant regular pace, otherwise the yarn so spun will lose its principal support, which is its proper turn, or twist, and will be little stronger than a parcel of straight hemp laid together, which would break in warping or straining up. The following regulations must be attended to in spinning. Every spinner is to spin out of the best hemp six threads, one hundred and sixty fathoms long, for a quarter of a day's work; but he is to spin out of the hemp which compose the bands by which the bales of hemp are bound together, no more than four threads, one hundred and sixty fathoms long, for one quarter of a day's work. To every twelve spinners there are allowed two hatchellers, one wheel-turner, and one wheel-tender: the wheel-tender's business is to splice the threads, and wind them on winches. The latter mentioned persons are paid in the same proportions as the spinners, that is, according to what work is done upon the wheel, only with this difference, the spinners are paid seven-pence per quarter for their work, the hatchellers, wheel-turner, and wheel-tender, only sixpence.

Each thread of the under-mentioned sizes of yarn to the spinning mark, (viz. 160 fathoms,) should weigh as follows:

	lbs.	oz.	drs.		lbs.	oz.	drs.
16	4	0	0	21	3	0	4
17	3	12	4	22	2	14	9
18	3	8	14	23	2	12	8
19	3	5	14	24	2	10	10
20	3	3	3	25	2	8	15

The third process to be attended to in the manufacturing of cordage, is *Warping the Yarn*.

Warping the yarn, is the stretching the yarns, previously to their being tarred, all to one given length, which, in full length rope grounds, is two hundred fathoms, and putting a slight turn or twist into it. The usual method is to warp the yarn either in whole or half hawls, which is done by putting the number of threads you mean to draw down at once in a bite, into a block with one sheave, (the one end of the bite of yarn being fast at the upper end,) which being drawn down and fixed over the end of a hook made fast to a post at one hundred fathoms distance from the warping post, forms, when opened, a length of two hundred fathoms, as above-mentioned. The number of half bites, or blocks of yarn, contained in a whole or half hawl, is to be governed, in a great measure, by the size of the yarn to be warped,—as, for instance, 16 to 19-thread yarn is warped three hundred and thirty-six threads in a hawl, 20 to 25-thread yarn is warped four hundred threads in a hawl. In winding the yarns on the winches after they are spun, it is most usual to wind them on in companies of four in a company; but as that method can-

## ROPE-MAKING.

not always be pursued, it frequently happens that whole or half hawls of yarn are obliged to be warped in half bites of an odd number.

The following rules and regulations respecting the warping of yarn must be particularly attended to.

In a hawl of yarn containing three hundred and thirty-six threads, there should be warped as under-mentioned.

$\frac{3}{4}$ Bites.	Threads.	of	9 threads in a $\frac{1}{2}$ bite.
37	3	of	9 threads in a $\frac{1}{2}$ bite.
33	6		ditto.
30	6		ditto.
28	0		ditto.
25	11		ditto.
24	0		ditto.
22	6		ditto.
21	0		ditto.
19	13		ditto.
18	12		ditto.
17	13		ditto.
16	16		ditto.

In a hawl of yarn containing four hundred threads, there should be warped as under-mentioned.

$\frac{3}{4}$ Bites.	Threads.	of	9 threads in a $\frac{1}{2}$ bite.
44	4	of	9 threads in a $\frac{1}{2}$ bite.
40	0		ditto.
36	4		ditto.
33	9		ditto.
30	11		ditto.
28	8		ditto.
26	10		ditto.
25	0		ditto.
23	9		ditto.
22	4		ditto.
21	1		ditto.
20	0		ditto.

When the yarn is warped in half hawls, it is to be carefully observed that only half the number of yarns, or threads, above-mentioned, are to be warped, and care should be taken to warp the number of threads as near as possible.

It requires three men to warp a hawl of yarn, who are employed as follows: viz. two men to warp (or draw the yarns to their proper distance), and one man to set up (that is, to tighten the yarns, and bring each yarn to its proper bearing): each man is allowed twelve threads (or two quarters of a day's work) for his labour.

To take the hawl of yarn up after it is warped, and carry the same into the tar-house, requires ten men, who are each paid one thread (viz. one penny) for their labour.

The fourth process to be attended to in the manufacturing of cordage, is *Tarring the Yarn*.

Tarring the yarn is a process which should be particularly attended to, being extremely careful that the tar is not boiling too fast nor too slow; if too fast, the tar will not stay in the yarn, if not hot enough, the tar will not sufficiently penetrate the yarn; therefore a strict medium must be carefully observed by the kettle-heater, as well as to keep the horse, or men, which turn the capstan round, going at a gentle, steady pace, thereby giving the yarn a proper time to imbibe its necessary proportion of tar, but at the same time not suffering it to be kept in the boiling tar too long, which is apt to make the yarn very tender, therefore should be very carefully avoided; and should the capstan be stopped by accident, the stop that keeps the yarn down must be instantly raised, and the yarn taken out. Particular attention

should also be paid in paying (or coiling) the yarn into the kettle, that too long a length be not payed in at once; if it is so done, the yarn will, of course, touch the bottom of the kettle, which it should, by no means, be suffered to do, as in such case it will imbibe the dregs and settlements of the tar appertaining to the bottom of the kettle, and make the yarn in such places black, or very much discoloured, and have a very unpleasing appearance in the rope when made. Yarn for cables requires more tar than for hawser-laid ropes. For standing and running rigging the less tar the better, provided the thread is well covered. It should be always remembered that the yarn, when tarred, should be overfret (or removed) the same day, as this piece of business, being omitted, will be likely to prove of a serious consequence in heating and tendering the yarn, which at all times must be carefully avoided. In overfretting the yarn it should always be remembered that the yarn be well shook and opened for two or three days, as in so doing it admits the air, separates and hardens the yarns, and contributes very much to the strength of the cordage. The hawls or half hawls of yarn, when tarred, should always be weighed and talhed.

Tarring yarn requires three men, who are employed as follows: viz. one to heat the kettle, one to pay (or coil) the yarn in the kettle, and one to haul off and overfret the yarn. They are, in general, paid in proportion to the work the spinners perform, which is called going by the wheel.

The fifth and last process to be attended to, is *Laying the Cordage*.

In laying cables, and all sorts of ropes in general, the great art lies in making each yarn to bear alike. For this purpose it was, particularly in the larger sized cables, that the patent machines have been introduced. Particular attention must be paid to this point, as therein consists the grand principle of making a strong rope. For all sorts of ropes which are to be immersed in the water, the utmost care must be taken to give the strands their proper hardness in their first process, according to the remarks laid down before, which will prevent the water from penetrating the strands, and thereby preserve the inside yarns of the cable; as, if this process is not regularly attended to, the inside yarns will be always wet, and very soon decay. It frequently happens that when the yarn is tarred somewhat too deep, that many a cable is spoiled, though not intentionally; the fear in the person who has the direction in making the cable, of turning a very dark coloured rope out of hand, prevents the regular make being given the cordage, as in pressing the yarn to their proper hardness, the tar will spring out, very much discolour the rope, and thereby give it a very unpleasing appearance, especially when the sun is shining very hot upon the yarn; to prevent which, in a great measure, care should be taken, in the summer months, to lay cables, and all sorts of cordage in general, either early in the morning, before the sun has much power on the yarn, which is also apt to tender it, or late in the evening, after the sun has set, or gone off the ground, or in heavy weather (by no means rainy); in which case your cordage will have a bright pleasing appearance, as the small fibres of the hemp will all yield to the top, and lay smooth, which otherwise would look rough, and appear as if the cordage was made of inferior hemp, though in fact it was not so, as all sorts of hemp have small fibres appertaining to them, and which it is past the art of man to prevent the sun from drawing up, and thereby making the rope look rough and unseemly.

N. B. The above remarks respecting taking advantage of the time for laying the cordage are only to be observed in uncovered grounds.

## ROPE-MAKING.

In *laying cordage*, the yarn for twisting into strands is hung on the hooks in the tackle-board, at the upper end of the ground, and upon hooks in the breast-board of the sledge, at the lower end, which are turned by men at both ends until the strands are hard; and are kept up from the ground by the stake-heads.

Before the turn is put in, the yarn should be stretched to its full extent by means of the tackle fixed from the sledge to the capstern, at twenty yards asunder, at the lower end of the ground; and when stretched to two hundred fathoms, the press is put upon the sledge and drag, before the tackle-fall is cast off; for if the yarn be not properly stretched before the tackle-fall is cast off, the rope will not be of its size, nor well made.

The strands should have a good hardening before the top is put in to lay the rope, and the layer should see that the heavers at the upper end keep the same hardness that the strands had before the top set off, nor should he begin to lay the rope until the sledge or wheel is moved by the power of the twist from the upper end.

When twisted sufficiently hard, the strands are hung on one hook in the breast-board of the sledge, but remain separate on the three hooks at the other end. The top is placed in at the sledge, and the rope twisted by turning the hooks at both ends one way, and, as the rope closes, the top moves towards the upper end.

When the top is put in, some of the weight should be taken off the sledge or drag, for if laid with as much weight as is used in the hardening, it would be too stiff, but, by removing a part of the weight, the strands will couch better.

The strength of the men at the hooks being greatly inadequate to the force required for twisting of cables, woodlads are used, according to the size of the cable, at equal distances along the whole length.

Cables should be rounded by the lower hook after they are laid, to throw the turn well up. They are generally thought to wear best when slack-laid; but some think when short-laid.

Cablets used for tow-lines or hawsers, require the strands to be laid shorter than cable-strands, but not so short-laid in closing; for being used in water, they would become stiff, hard, unhandy to coil away, and liable to break in cold weather.

In all cable-laid ropes, the proportion of the circumference is to the length of the strand in one round, as 11 is to 15; that is, if the circumference be  $14\frac{1}{2}$  inches, the length of the strand in one circumference is  $19\frac{1}{2}$  inches. In all hawser-laid rope, the proportion is as 12 to 16; that is, if the circumference be 7 inches, the length of the strand in one circumference is near 9 $\frac{1}{2}$ .

The strength of ropes depends on the hardening or well manufacturing, and not on the bare strength of the hemp; for it strengthens through every stage; *viz.* when first spun into yarn it is little better than hemp extended; when

twisted into strands, it shortens and strengthens as above, and increases in the same manner when laid into rope.

Where the diameter and circumference of one rope to another is as two to one, that is, where one rope is twice as big as another, the square of the diameter is as four to one; which shews, that one rope has four times as much yarn in it as the other, and consequently is four times as strong, according to the different magnitudes.

Cable-laid ropes shorten as five to three, and hawser-laid ropes as three to two; consequently the length of the yarn and strength will be accordingly; that is, the strength will be in the yarn, after it is laid in the rope, as much as if the rope-maker, in spinning, had allowed the same quantity of hemp in two feet as he did in three feet, so that the strength communicated by the process is two-thirds.

A rope is the same size when laid as the yarns were before twisted; so that what the yarns are lessened by twisting it is made up by shortening; from which it is inferred, that the yarns are always of an equal bigness, since the hemp is the same at one time as at another, and not any way diminished.

Were the strands single, without being twisted one about another, the strength would then be only in proportion as the area of each particular strand is in itself; but if the strands could possibly be twisted so as to be directly perpendicular to the base, the strength would then be found, by multiplying the diameter of the strands and the diameter of the whole rope one into the other, and the half of the product would be the strength of the said strands; but more particularly take the area of the single strand and area of the whole cable, and add them together, and the half of that will shew the strength of each strand when they are well twisted together.

But as it may be observed the strands lie at a certain angle between a perpendicular and the base, so that, as the angle of incidence is to radius, so is the relative to the absolute strength.

Respecting the *Bandage of Cordage*.—In the calculations specifying the weights of the different lengths of cordage, such weights are to be considered as the neat weights of the rope without bandage.

N. B. To every hundred weight of cordage the manufacturer is allowed to put on four pounds weight of bands; those bands are composed of the shakings, flyings, and strings with which the hemp is tied together, formed into an inferior kind of cordage; but it is to be observed those are all weighed to the rope-makers as good hemp, and paid for accordingly, therefore if he was not allowed to apply the refuse to such purpose, he must either put a higher price on his cordage, or be a very considerable loser. At the same time it should be considered, that as it is necessary that every coil of rope should be bound together for the convenience of carriage, stowage, &c. this kind of bandage answers such purpose in every degree, as well as if the coils were bound with bands made from the best hemp.

# ROPE-MAKING.

## TABLE I.

These sizes of Yarn are warped 336 Threads, and from 19 are warped 400 Threads in a Hawl.

												144 0 0	42	*10	108	18

\* Six threads are called a quarter of a day's work, for which each workman is paid 7d., and so on in proportion for a greater or less number.

*Remarks and Directions how to apply Tables I. and II.*

*Example.*—Suppose a cable of 12 inches in circumference is wanted to be made, the hawls of yarn out of which, upon examining the weights, are found to weigh 16 cwt. 2 qr. 10 lb. *per* hawl of 336 threads. A reference is to be made to Table I. line E, and the weight, being between 16 cwt. 2 qr. 0 lb. and 16 cwt. 2 qr. 18 lb. will be found to answer to 18-thread yarn. Then look down the 18-thread column, Table II., and upon the line of 12, (the size in the margin,) is found 80 threads *per* hook, which is the number of threads to be laid up *per* hook for the cable to be made of the weight *per* hawl of yarn of 336 threads above specified.

Again, if the hawls of yarn should be tarred of such a weight (say for example) requires to be worked between a

17 and an 18-thread yarn, in such case take the number of threads *per* hook to be worked for the size of the cable demanded, as should be worked both for 17 and 18-thread yarn; add them together, and take half the number of threads so added, to work *per* hook for the cable; but if there should happen in dividing to be an odd thread remaining, you must observe to which side the weight of your hawl of yarn is most inclining, and throw the thread in dispute to the heaviest side. The same rules must be observed in consulting all the following tables.

*Remarks.*—In laying three-strand cable-laid cordage, if you are in doubt respecting the size of your yarn, you must girt the yarn you purpose laying in one strand, and that should be half the size of your cable.

In hardening the strands in the laying of cable-laid cordage,

# ROPE-MAKING.

cordage, you must work with (in addition to your sledge) one prefs-barrel to every 20 threads contained in your strand; but in laying the strand, hardening, and laying the cable, you must have only one prefs-barrel to every 40 threads contained in your strand or cable. The above is to be considered as a standing rule in covered rope-grounds, but in open grounds, the prefs must be varied according to the state of

the bottom of the ground, which, after a shower of rain, or in damp weather, will be naturally soft, and occasion the sledge to draw exceedingly heavy, and of course want the less weight of prefs.

N. B. The weight of a prefs-barrel should be from  $3\frac{1}{2}$  to 4 cwt.

TABLE III.

Shewing the different shrinking Proportions of the Yarns and Strands in each Process in making the undermentioned Lengths of Cable.

	Length in fathoms of cable.	Length of yarns required to be warped.	In hardening the strands, the yarn will shrink 1-5th part of the whole length warped, and is called the strand's hardening mark.	In laying the strands, the strand will shrink 1-10th part of the whole length warped, and is called the strand's going distance.	In hardening the cable-strands previous to laying the cable, the strands will shrink 1-30th part of the whole length warped, and is called the cable's hardening mark.	In laying the cable it will shrink 1-15th part of the whole length warped, which brings it to the length required.
The Sledge should move up to the following Distances from the Tackle-Posts.						
	fms.	fms. ft.	fms. ft.	fms. ft.	fms. ft. in.	fms.
$\frac{1}{3}$ Cable	40	66 4	53 2	46 4	44 2 8	40
$\frac{1}{2}$	60	100 0	80 0	70 0	66 4 0	60

$\frac{1}{2}$	60	1 0 14 0	4 2 0 0	10 0 14 0	18 0 0 0	28 0 14 0	40 2 0 0	55 0 14 0	72 0 0 0
$\frac{2}{3}$	80	1 2 0 0	6 0 0 0	13 2 0 0	24 0 0 0	37 2 0 0	54 0 0 0	73 2 0 0	96 0 0 0
Whole	120	2 1 0 0	9 0 0 0	20 1 0 0	36 0 0 0	56 1 0 0	81 0 0 0	110 1 0 0	144 0 0 0

It is necessary to be understood, that in rope-making (according to the nature of the rope), weight will give size, and size will give weight, if properly made.

*Rule.*—To calculate very nearly the weight of any sized rope from 3 to 24 inches in circumference, 120 fathoms long, and lesser lengths in proportion; as may be readily proved by the above table, *viz.* multiply the size of the rope by itself, and one-fourth of that product is the weight of a hundred of 112 pounds.

*Example.*—Suppose the rope 12 inches in circumference;  $12 \times 12 :: 144$ , the fourth of which is 36 hundred weight, or 372 pounds, the weight of 120 fathoms of rope 12 inches in circumference. Again, 40 fathoms is the third of 120 fathoms; and the third of 36 cwt. is 12 cwt. the weight of 40 fathoms of 12-inch cable, as above.

*Directions how to apply the following Tables.*

In which is considered the four most principal sorts of yarns made use of in cable-laid cordage, *viz.* 16, 18, 20, and 25-thread yarn, and in hawser-laid cordage, to the three principal sorts of yarn made use of, *viz.* 18, 20, and 25-thread yarn, as it is very seldom any other size yarn is made for either cable or hawser-laid rope, except very particularly ordered to the contrary. The particulars of every rope of the sizes mentioned in the tables are fully explained

to the length of twenty fathoms, which will be found quite a sufficient guide for a rope of any length required :

*As for Example.*—Suppose I want a taper cable-laid rope to be made out of 16-thread yarn, 60 fathoms long, and 6 inches in circumference, to be tapered  $\frac{3}{4}$ ds the length, and  $\frac{3}{4}$ ds the size of the rope. I refer to Table V., and find under the figure 6, (the size demanded,) that it must be worked 5 threads *per* hook in the shank, the length of yarn to be warped for which, for 20 fathoms (I find in the margin) requires to be 33 fathoms 2 feet, three times which is 100 fathoms, the length of yarn required to be warped for the shank of a rope of 60 fathoms long. I then observe, in the next column on the right in the margin, the length of yarn required in the head for 20 fathoms is 11 fathoms 0 feet 8 inches, three times which is 33 fathoms 2 feet, the length of yarn required in the head to the first taper for a rope of 60 fathoms. Next refer to the number of tapers to be worked, which, upon looking under the figure 6, (the size demanded,) I find to be 9, the distance between them I find (upon calling my eye down the column) to be 14 feet  $7\frac{3}{4}$  inches for 20 fathoms, three times which is 44 feet  $5\frac{3}{4}$  inches, the distance to be observed between the tapers for a rope of 60 fathoms, being the length demanded. The same rule is to be observed, either adding or multiplying, according as required in all the tables of a similar description.

# ROPE-MAKING.

TABLE V.—continued.

To Taper half the Length and half the Size of the Rope.

Fathoms demanded.	Lengths of Yarn in Shank or whole Parts.	Lengths of Yarn in the Head to the first Taper.	Lengths of Yarn in the Taper.	Distance between the Tapers.

# ROPE-MAKING.

TABLE VI.

Shewing the Number of Threads to work *per* Hook and Heart for cable-laid Stays, four Strands and a Heart, of 5, 10, 15, and 19 Inches in Circumference, of the undermentioned Sizes of Yarn, with the Girt of each Strand prefixed against each Size.

Number of Threads afunder to weigh from 99 to 100lb.		16	17	18	19	20	21	22	23	24	25
Size in Inches.	Girt of each Strand.	Threads <i>per</i> Hook and Heart.									
5	2 $\frac{3}{4}$	9	9	10	11	11	12	12	13	13	14
10	4 $\frac{1}{2}$	35	37	39	41	43	46	48	50	52	55
15	6 $\frac{1}{2}$	79	84	89	94	99	104	109	114	119	124
19	8 $\frac{1}{2}$	127	135	143	151	159	167	175	183	191	199

The shrinking proportions of cable-laid stays are exactly the same as in three-strand cable-laid cordage, except in the closing the stay, which being composed of four strands, lie much closer in the rope than three strands, and having the heart of the stay to encompass, occasions the strands to shorten in a much greater proportion than in three-strand cable-laid cordage. The stay, in closing, will shorten  $\frac{2}{7}$  parts of the length of yarn first warped.

TABLE VII.

Shewing the Weight of cable-laid Stays, four Strands and a Heart, from 5 to 19 Inches in Circumference, and from 5 to 30 Fathoms in Length.

# ROPE-MAKING.

TABLE IX.

Shewing the Length of Yarn required to be warped, and the different shrinking Proportions in making the undermentioned Lengths of four-strand cable-laid Cordage.

Fathoms demanded.	Lengths of Yarn warped.			Strand's Hardening Mark.			Strand's Going Distance.			Cable's Hardening Mark.			Cable's Length.
	fms.	ft.	in.	fms.	ft.	in.	fms.	ft.	in.	fms.	ft.	in.	
10	17	0	6	13	4	0	11	5	9	11	2	4	10
20	34	1	0	27	2	0	23	5	6	22	4	8	20
40	68	2	0	54	4	0	47	5	0	45	3	4	40
60	102	3	0	82	0	0	71	4	6	68	2	0	60
80	136	4	0	109	2	0	95	4	0	91	0	8	80
120	205	0	0	164	0	0	143	3	0	136	4	0	120

N.B. The shrinking proportions of four-strand cable-laid cordage is exactly the same as three-strand, except in closing the cable, which consisting of four strands, lie much closer in the rope than three strands, but not having a heart to encompass it, does not diminish in length so much as cable-laid stays. The cable in closing will shorten  $\frac{1}{12}$  parts of the length of yarn first warped.

It being rather unusual to lay cables with a greater number of strands than four, the above tables are not laid down for a greater proportion,—but to know how to find the number of threads to work *per hook* for a greater number may at some time be necessary, therefore the following method

must be pursued to lay a cable in as many strands as may be thought expedient. Suppose a five-strand cable-laid rope is wanted to be made, you first square the size of the rope proposed to be made, and multiply that product by the size yarn you mean to make your cable from, that product divide by 52, and the quotient will be the number of threads to work *per hook* for a five-strand cable-laid rope. If for a six-strand, proceed as before, and divide by 62; for a seven-strand, divide by 72; for an eight-strand, divide by 82; and so on, adding 10 to your divisor for every strand you mean to increase in number in your cable.

TABLE X.

Shewing the Prime Cost to the Manufacturer in each Process, in making the undermentioned Sizes of three-strand cable-laid Cordage, with the Weight of Hemp and Tar required for each Rope.

Size.	Hatchelling, Wheel-turning, and Tending.	Expence at 5d. per Quarter.	Spinning.	Expence at 7d. per Quarter.	Warping, Taking-up, and Tarring, at 9s. per Hwl.	Laying at 7d. per Quarter.	Total Expence of Manufacturing into Cordage.	Weight of Hemp required for each Rope.	Weight of Tar required for each Rope.
5	7 3	0 3 9	22 3	0 13 1	0 2 10 $\frac{1}{2}$	0 15 5	1 15 1 $\frac{1}{2}$	5 0 0	1 1 0
10	31 1 $\frac{1}{2}$	0 15 7 $\frac{1}{2}$	93 4 $\frac{1}{2}$	2 14 7 $\frac{1}{2}$	0 12 1	2 6 1	6 8 5	20 0 0	5 0 0
15	70 3 $\frac{3}{4}$	1 15 3 $\frac{3}{4}$	211 5 $\frac{1}{4}$	6 3 6 $\frac{1}{4}$	1 7 3	5 17 10	15 3 11	45 0 0	11 1 0
20	125 0	3 2 6	375 0	10 18 9	2 8 2	11 18 0	28 7 5	80 0 0	20 0 0
24	180 0	4 10 0	540 0	15 15 0	3 9 5	15 11 6	39 5 11	115 0 23	28 3 5

The above table is calculated according to the usual mode of rope-making, and is termed by the trade working by the square, which is performed in the following manner: Suppose a cable 15 inches in circumference, the square of 15 is 225, the half of which is 112 $\frac{1}{2}$ ; that is, 113 threads *per hook* must be laid up for a 15-inch cable, proceeding in the same manner for any size demanded, which mode of working answers to

sixteen-thread yarn in all sizes of three-strand cable-laid cordage.

Where the diameter and circumference of one rope to another is as 2 to 1, that is, where one rope is twice as big as another, the square of the diameter is as 4 to 1, which shews that one rope has four times as much yarn in it as the other, and consequently is four times as strong, according to the different magnitudes.

# ROPE-MAKING.

TABLE XI.

Shewing the Number of Threads *per* Hook to work for three-strand hawser-laid Cordage, of 3, 6, 9, and 12 Inches in Circumference, of the Sizes of Yarn undermentioned, with the Weight of each Rope, and the Number of Men required to lay the same, with the Allowance to each Man for his Labour.

N <sup>o</sup> of Threads 99 to 100lb. Weight.	16	17	18	19	20	21	22	23	24	25	Weight of each Rope 133.2 long.	Men for Rope.	Threads per Rope.
	Threads <i>per</i> Hook.												
Size in Inches.											C. qr. lb.		
3	16	17	18	19	20	21	22	23	24	25	2 2 17	8 0	6
6	64	68	72	76	80	84	88	92	96	100	10 2 12	22 0	12
9	144	153	162	171	180	189	198	207	216	225	23 1 13	37 0	15
12	256	272	288	304	320	336	352	368	384	400	42 1 20	45 0	15

*Remarks.*—In hardening the strands, and in laying hawser-laid cordage, it must be worked with (in addition to the weight of the sledge) one prefs-barrel for every twenty threads contained in the rope. This is to be considered as a standing rule in covered rope-grounds, but in open grounds the prefs must be varied according to the state of the ground, as mentioned in cable-laid cordage.

In laying three-strand hawser-laid cordage, if there is any doubt respecting the size of the yarn, you must girt the yarn you propose laying in two of your readys (or strands), and that should be just the size of the rope.

TABLE XII.

Shewing the Length of Yarn required to be warped, and the different shrinking Proportions of the Yarn in each Process, in making the undermentioned Lengths of hawser-laid Rope, and also the Weight.

	Fathoms of Rope in Length.		Length of Yarn to be warped.		The Sledge should move to the following Marks from the Tackle-Posts.		¾-Inch.	1½-Inch.	2-Inch.	4-Inch.	6-Inch.	8-Inch.	10-Inch.	12-Inch.
	fms. ft.	fms.	fms.	fms. ft.	Rope's Hardening Mark.	Rope's Length.	Weight.	Weight.	Weight.	Weight.	Weight.	Weight.	Weight.	Weight.
Half } Coil }	10 0	15	12	10 0	0 2 7½	0 4 15	0 0 9 14½	0 1 11 9½	0 3 5 12½	1 1 18 6½	2 0 23 8	3 0 20 6	4 1 19 0	5 0 20 6

	40 0	60	48	40 0	0 9 14	0 19 12	0 1 11 9	1 1 18 6	3 0 20 6	5 2 17 9	8 3 10 8	12 2 25 8	16 2 26 0	21 0 24 0
	66 4	100	80	66 4	0 16 8	1 5 0	0 2 10 0	2 1 12 0	5 1 6 0	9 1 20 0	14 2 26 0	21 0 24 0	28 0 23 0	35 1 23 0
	80 0	120	96	80 0	0 19 12	1 11 8	0 2 23 2	2 3 8 12	6 1 12 12	11 1 7 2	17 2 20 0	25 1 23 0	33 0 7 12	41 0 7 12
	100 0	150	120	100 0	0 24 11	1 21 6	0 3 14 14½	3 2 3 15	7 3 22 15	14 0 15 14½	22 0 11 0	29 0 7 12	37 0 20 8	45 0 20 8
Whole } Coil }	120 0	180	144	120 0	1 1 10	2 3 4	1 0 6 11	4 0 26 2	9 2 5 2	16 3 24 11	26 2 2 0	33 0 20 8	41 0 20 8	49 0 20 8
	133 2	200	160	133 2	1 5 0	2 10 0	1 0 20 0	4 2 24 0	10 2 12 0	18 3 12 0	29 1 24 0	37 1 20 0	45 1 20 0	53 1 20 0

*Remarks.*—In hardening the strands the yarn will shrink one-fifth of the whole length, which is called the rope's hardening mark.

In laying the rope the strands will shrink one-sixth of the remaining distance, which brings the rope to the length required.

# ROPE-MAKING.

TABLE XIII.

Shewing the exact Cost to the Manufacturer in each different Process as undermentioned, in making the following Sizes of three-strand hawfer-laid Cordage, with the proper Proportions of Hemp and Tar necessary for each Rope.

12	60 0	1	10	0	180	0	5	5	0	1	3	2	3	5	7	11	3	9	33	3	22	8	1	26

The foregoing table is grounded (as termed by the trade) upon the principle of the square, but the method of working upon this principle differs between cable and hawfer-laid cordage. The mode pursued for making hawfer-laid cordage is as follows: Suppose it is wanted to make a three-strand hawfer-laid rope, six inches in circumference; the

square of 6 is 36, and twice 36 is 72, which is the number of threads to work *per hook* for a six-inch three-strand hawfer-laid rope. The same method must be pursued, according to this way of working, for any other size, and answers to eighteen-thread yarn in all three-strand hawfer-laid cordage. See Table XI.

TABLE XIV.

Shewing the Weight of Yarn (of the four most general Sorts made of) capable of being spun by each of the following Number of Spinners, at eight Quarters, (or 48 Threads) *per day*, in 1 Day, 1 Week of 6 Days, 1 Month of 24 Days, and 1 Year of 13 Months; with the Yield of Cordage at the Year's End prefixed against each Number of Spinner's Work.

# ROPE-MAKING.

Suppose you want to make a rope either cable or hawser-laid, to be tapered one-third the length, and one-third the size; you must refer to Table V. or XIV. for making taper-cable, or hawser-laid cordage, two-thirds the length and two-thirds the size, which you must work almost wholly the reverse way, by working the number of threads there mentioned to be worked in the tapers in the shank, and the number of threads in the shank must be worked in the tapers: the length of yarn there mentioned to be tapered must be the length in the head to the first taper, and the length

there mentioned in the head must be the length of the yarn to be tapered: the length of yarn requested to be warped for the shank will be the same as there mentioned, and the distance between the tapers will, in almost all cases, be the same as there nominated; but if at any time there should be a difference, and you are at a loss to find the distance between the tapers you must divide the length of yarn to be tapered by the number of threads you have to taper, and that will give the exact distance between them.

TABLE XVI.

Shewing the Number of Threads to work *per* Hook for four-strand hawser-laid Cordage, from 2 to 12 Inches in Circumference, of the Sizes of Yarn as undermentioned: the Ropes to be laid without Hearts, the Yarns comprising which being equally divided in the Strands.

No. of Threads here mentioned to weigh 99 to 100 lb.	16	17	18	19	20	21	22	23	24	25
Size in Inches.	Threads <i>per</i> Hook.

TABLE XVII.

Shewing the Length of Yarn requested to be warped for the undermentioned Lengths of four-strand hawser-laid Cordage, with the Hardening Mark prefixed against each respective Length.

Fathoms demanded.	Length of Yarn required.			Hardening Mark.		
	fms.	ft.	in.	fms.	ft.	in.
10	15	2	6	12	2	0
20	30	5	0	24	4	0
40	61	4	0	49	2	0
60	92	3	0	74	0	0
80	123	2	0	98	4	0
100	154	1	0	123	2	0
120	185	0	0	148	0	0
130	200	2	6	160	2	0

*Remarks.*—It is very seldom that hawser-laid cordage is composed of more than four strands, but for the sake of experiment, or otherwise, it might be demanded to contain a greater number: as such, the following rule, carefully attended to, will inform our readers how to lay a hawser-laid rope in as many strands as may be considered expedient.

Suppose you want a five-strand hawser-laid rope, you must square the size of the rope proposed to be made; that product multiply by the size yarn you propose making your rope from; the product of which, divided by 15, will give the number of threads to work *per* hook for a five-strand hawser-laid rope. If you want to make a six-strand hawser-laid-rope, you must proceed as above, and divide by 18; if a seven-strand, divide by 21; if an eight-strand, by 24; and so on, adding 3 to your divisor for every strand you mean to increase in the rope.

The shrinking proportion in making four-strand hawser-

laid cordage, in the first process, is exactly the same as in three-strand; the only difference is in closing the rope, which, being composed of four strands, occasions the rope to lay more round and close than in three-strand cordage, which makes the shrinkage be in a much greater proportion. The rope, in closing, will shorten  $\frac{1}{8}$ th parts of the remaining length of yarn, after the rope is hard, instead of  $\frac{1}{6}$ th, as in three-strand hawser-laid cordage.

The weight of each coil of four-strand hawser-laid cordage may be nearly ascertained, by referring to the table of the weight of three-strand (Table XII.), there being as near the number of threads in each size rope as can possibly be laid, for each strand to have an equal number. But it should be remembered, that a coil of four-strand hawser-laid rope, made out of 200 fathoms of yarn, will be only 130 fathoms long, instead of 133.2, as in three-strand hawser-laid cordage.

# ROPE-MAKING.

*Remarks.*—In hardening the strands, the yarn will shrink one-sixth part of the whole length, which is called the rope's hardening mark.

In laying the rope, the strands will shrink one-seventh part of the remaining distance, which brings the rope to the length required.

N. B. Bolt-rope is usually made of 20 or 25-thread yarn, and generally delivered from the rope-maker white;

the process of tarring it being usually performed by the sail-maker, and is called stoving it, it being done in a stove or oven calculated for the purpose. In laying up your work, you must work with the same number of threads as in common hawser-laid cordage. Bolt-rope, for exportation, is sometimes lightly tarred; in which case, in calculating the weight, you must add one-sixth to the weights hereunto annexed.

## TABLE XIX.

Shewing the Number of Threads to work *per* Hook for three-strand hawser-laid white Cordage, from 1 to 12 Inches in Circumference, of the undermentioned Sizes of Yarn, with the Weight of each Rope prefixed.

No. of Threads the mentioned to weigh 68 lbs.	16	17	18	19	20	21	22	23	24	25	Weight of each Rope 133.2 Fathoms long.
	Threads <i>per</i> Hook.										
Size in Inches.											C. qr. lb.

12	288	304	320	336	352	368	384	400	416	432	37 2 24

N. B. Especial care should be taken relative to making white cordage for tackle-falls, crane-ropes, &c. that the hemp be of the very best quality; and that the same be topped, *viz.* all the short hemp taken out by the hatcheller;

and that the spinner do spin his yarn for the same exceeding smart and even, by no means lighter than the weight specified under the article *spinning the yarn*: if he does, his rope will not answer the size required to be made.

# ROPE-MAKING.

TABLE XX.

Shewing the Number of Threads to work *per* Hook for four-strand hawser-laid white Cordage, without Hearts, from 2 to 12 Inches in Circumference, of the Sizes of Yarn as undermentioned.

No. of Threads here-mentioned to weigh 85 lbs.	16	17	18	19	20	21	22	23	24	25
	Threads <i>per</i> Hook.									
2	6	6	7	7	7	8	8	8	9	9

12	216	228	240	252	264	276	288	300	312	324

N. B. The weight of the above ropes may be found by consulting Table XVII. for three-strand hawser-laid white cordage; the number of threads in each rope of a size being of an equal number, as near as possible.

*Cordage made by Contract for the Use of His Majesty's Navy.*—The under-mentioned shews the number of threads to work *per* hook; the lowest weight, allowance in weight, bandage, and highest weight; the cordage is to be received and allowed for by the receiving officers of his majesty's re-

spective dock-yards, under the honourable commissioners of his majesty's navy, to rope-makers who have made cordage (upon the usual principle) by contract, in coils, hawsers, cablets, and cables, with the length of yarn to be warped for the same, and length of cordage when made, as ordered by the honourable navy-board.

N. B. The highest weight a hawl of yarn for each fort of cordage should weigh (and by no means more,) is here noted.

TABLE XXI. Cablets.

11	70	25 2 10	0 2 15	26 0 25
11½	76	27 3 4	0 2 22	28 1 26
12	83	30 1 10	0 3 1	31 0 11
12½	90	32 3 17	0 3 8	33 2 25
13	98	35 3 9	0 3 16	36 2 25
13½	106	38 3 1	0 3 25	39 2 26
14	114	41 2 20	1 0 5	42 2 25
14½	122	44 2 12	1 0 12	45 2 24
15	130	47 2 3	1 0 21	48 2 24
15½	139	50 3 7	1 1 2	52 0 9
16	148	54 0 13	1 1 11	55 1 24
16½	157	57 1 16	1 1 20	58 3 8

It is to be observed, that the above sizes in Tab. XX., viz. 2 to 9½ inches, are termed, in the navy contracts, cablets, the yarn for which should be warped 200 fathoms long, and the cablets, when complete, to be 120 fathoms. A hawl of yarn containing 336 threads, should weigh from 16 cwt. 0 qr. 8 lb. to 16 cwt. 1 qr. 25 lb., and no more, allowing one-sixth part of such weight for tar, which is the allowance made by the honourable navy-board, and no more.

Cablets from 4 to 9½ inches will not be rejected, if they are half an inch in girth above the dimensions ordered.

The yarn for the above cables (Tab. XXII.) are warped 166 fms. 4 ft. long, and the cables, when complete, to be 100 fathoms long. A hawl of yarn containing 336 threads, 166 fms. 4 ft. long, should weigh from 13 cwt. 2 qr. 6 lb. to 13 cwt. 3 qr. 16 lb., and no more, tarred with the same proportion of tar as the yarn for the cablets before-mentioned.

## ROPE-MAKING.

Cables 10 inches and upwards, are allowed three-fourths of an inch in girt more than the dimensions given.

In proportions of cordage wherein the cables contained in them do not exceed  $13\frac{1}{2}$  inches in circumference, a proportion of  $1\frac{1}{2}$  cwt. of spun-yarn is allowed to be sent to every ton of cordage; but if the cables are 14 inches in circumference and upwards, then 3 cwt. for every ton is allowed, in order to work up the topplings (or hemp) which should be taken out of the hemp agreeable to contract, previous to its being spun into cable-yarn (in particular), as it frequently happens that the great number of lives of some of his majesty's most valuable subjects are at stake upon the dependance of a single cable.

The cables made in the usual mode, by contract, have of late never exceeded  $16\frac{1}{2}$  inches in circumference, (Tab. XXII. extends no further): for all the higher sizes are made by patent machines, by which much manual labour is spared, and the yarns and strands laid much closer and more even, and bear the strain more equally.

Size.	Threads per Hook.	Lowest Weight.	Allowance in Weight.	Baudage.	Highest Weight.
		C. qr. lb.	C. qr. lb.	C. qr. lb.	C. qr. lb.
$\frac{3}{4}$	2	0 1 4	0 0 1	0 0 1	0 1 6
1	3	0 1 20	0 0 1	0 0 1	0 1 22
$1\frac{1}{2}$	6	0 3 13	0 0 2	0 0 2	0 3 17
2	9	1 1 6	0 0 4	0 0 4	1 1 14
$2\frac{1}{2}$	14	2 0 5	0 0 6	0 0 6	2 0 17
3	20	2 3 20	0 0 8	0 0 9	3 0 9
$3\frac{1}{2}$	26	3 3 7	0 0 11	0 0 11	4 0 1
4	35	5 0 14	0 0 14	0 0 16	5 1 16
$4\frac{1}{2}$	44	6 1 22	0 0 18	0 0 20	6 3 4
5	54	7 3 19	0 0 22	0 0 24	8 1 9
$5\frac{1}{2}$	65	9 2 2	0 0 27	0 1 1	10 0 2
6	77	11 1 3	0 1 4	0 1 7	11 3 14
$6\frac{1}{2}$	91	13 1 11	0 1 9	0 1 13	14 0 5

The sizes of cordage hereunto annexed, from  $\frac{3}{4}$  to  $3\frac{1}{2}$  inches in circumference, are termed, in the navy, contract coils; all above, viz. 4 to  $6\frac{1}{2}$  inch, are called hawsers. The yarn for both coils and hawsers should be warped 195 fathoms long, and the ropes, when completed, are to be 130 fathoms long. A hawl of yarn, consisting of 336 threads, 195 fathoms long, should weigh from 16 cwt. 1 qr. 7 lb. to 16 cwt. 2 qr. 24 lb. and no more, tarred in the same proportion as cables and cables.

All cordage delivered into his majesty's dock-yards undergo a trial, which is, by proving one strand out of each rope, each thread (or yarn) of which having a weight, weighing one-third of an cwt. made fast to it, which it should lift; but if a certain number of yarns (according to the size of each rope) should break in the trial, the rope is rejected, otherwise it is received.

Particular attention should be paid not to send any kind of cordage into his majesty's dock-yards above its highest weight, allowed according to contract, as, in such case, all above that weight will be a loss to the manufacturer; the receiving officer not being authorized to allow any more than is specified in the contract.

N. B. It is to be observed, that, in making cordage by contract for the use of his majesty's navy, his majesty finds his own hemp, the contractor tar and labour at a certain price per ton. All cables and cordage to be tarred with good Stockholm tar, without mixture of any

other, except about one-third part, which may be of Russia tar.

A white thread, twilled the contrary way, (sometimes called the rogue's yarn,) is to be laid in all the strands of the cables and large cordage; and a twine in the small cordage for the king's mark, so as to be seen on the outside of the strands.

In any of the strands, there is to be no greater number of threads at the ends of the cables or cordage than in the middle.

The only parliamentary regulations, relative to the manufacture of cordage, are contained in the following act; "An act for more effectually preventing deceits in the manufacturing of cordage for shipping; and to prevent the illicit importation of foreign-made cordage." 25 Geo. III. c. 56.

In July 1799, a patent was granted to W. Chapman and E. W. Chapman, of Newcastle-upon-Tyne, for their improved method of making cords and ropes, twined and untwined, from the spinning of the yarn inclusive, to the finishing of the rope or cordage. This invention appears, by the specification, to include material improvements in the spinning of rope-yarn, and in the manufacturing of cordage. Rope-yarns are at present spun by men, at an expence of from half a crown to five shillings per day, according to the situation of the place, whether in the out-ports, or on the river Thames. Or it is wholly spun by machinery.

In the practice of the first method rope-walks are necessary, and the fibres of the hemp are drawn into the yarn of different lengths proportionate in a given degree to their position in the outside or inside of the yarn; accordingly, when this yarn is strained, and its diameter collapses, the inside fibres of hemp bear the greatest strain, and thus they break progressively from the inside.

In the spinning by a mill the fibres are all brought forward in a position parallel to each other, previously to their receiving their twist. They are consequently all of one length; and, when twisted, the outside fibres are most shortened by forming the same number of spirals round a greater axis than the interior, and thus they must consequently break the first, on the same principle that the outside yarns of strands of ropes manufactured in the old method break before the interior yarns; and, consequently, with less strain than ropes of the improved principle, where the strands, (or immediate component parts of the rope) have been formed in such a manner as that all the yarns shall bear equally at the time of the rope's breaking.

Nevertheless, yarns spun by a mill have been found stronger than common yarns, on account of the great evenness with which they are spun; the manual labour in manufacturing is much less than in the common method: but, on the other hand, there is the expence of machinery, and the greater waste of hemp in preparing it for being drawn out in the progressive stages of its advance to the spindle.

The method invented by Messrs. Chapman differs from both the preceding, in having, by an easy and simple contrivance, the fibres of the hemp laid in the yarn in such a manner as the yarns themselves are laid in the strands of the rope manufactured on the new principle.

Their machinery consists only of a spindle, divided into two parts, the upper containing apparatus to draw forward the hemp from the spinner with twist sufficient to combine the fibres; which enables them to employ women, children, and invalids, and also to appropriate the rope-ground solely to the purpose of laying ropes.

The part we have described is only an improvement on

the methods of spinning, granted to Mr. William Chapman on the 8th day of November, 1798.

The remaining parts of their invention consist chiefly in the giving, from a stationary power, internal motion to a locomotive machine, *viz.* to the roper's sledge, on which the strands and the rope itself are twisted, by which contrivance they are enabled to apply a water-wheel, or steam-engine, to the whole process of making ropes of all kinds whatever.

Mr. Joseph Huddart of Ilington obtained a patent in August of the same year for an improved method of registering or forming the strands in the machinery for the manufacture of cordage. Having previously taken out a patent for this purpose, he contrived to effect it by the following means:

1. By keeping the yarns separate from each other, and drawing them from bobbins, which revolve, to keep up the twist whilst the strand is forming.

2. By passing them through a register, which divides them by circular shells of holes; the number in each shell being agreeable to the distance from the centre of the strand, and the angle which the yarns make with a line parallel to it, and which gives them a proper position to enter.

3. A cylindrical tube, which compresses the strand, and maintains a cylindrical figure to its surface.

4. A gauge to determine the angle which the yarns in the outside shell make with a line parallel to the centre of the strand when registering; and, according to the angle made by the yarns in this shell, the length of all the yarns in the strand will be determined.

5. By hardening up the strand, and thereby increasing the angle in the outside shell, which compensates for the stretching of the yarns, and the compression of the strand.

The patent which Mr. Huddart took out in August relates to the invention of a machine that may be worked by men, or any other power, and by means of which the registering may be commodiously and effectually carried on. But figures are necessary for describing intelligibly his peculiar contrivance. Mr. Huddart, in the following year, took out a patent for improvements in the method of turning cordage in the manufacture of it. But our limits forbid our enlarging on this article. The specifications of the patents for registering, as well as fastening, may be consulted by those who are concerned in this manufacture.

*Rope Walk*, or *Rope-house Ground*, is the place where ropes are manufactured. This should be 400 yards long, and about 10 broad. At the upper end are fixed the spinning-wheels, over which is the hatchelling-loft, also the back-frame wheels, tackle-boards, and posts, winches for winding the yarn on as it is spun, and reels on which to reel the ropes. On each side are stake-posts; in the middle is fixed the warping-post, and at the lower end, the capstern and reaching-post. Back-frame wheels for small, and sledges and drags for large ropes, are used towards the lower end; the back-frame wheel, for laying cordage from a six-thread ratline to a two-inch rope, is about four or five feet in diameter, and is hung between two uprights, fixed by tenons on a truck, and supported by a knee of wood. Over its top is a semicircular frame, called the head, to contain three whirls (that turns on the brasses) with iron spindles, secured by a half and pin. They are worked by means of a leather band encircling the whirls and the wheel. Three of the whirls are turned when hardening the strands, and one only when closing the rope, the strands being hung together upon it. The truck, on which the back-frame wheel is fixed, runs on four wheels, and is

made of three-inch oak plank, about nine feet long and thirteen inches broad at one end, and eleven inches broad at the other. The capstern, about eight feet high, and fourteen inches in diameter, is turned either by men or horses; its use is to draw the yarn, when tarring, out of the copper, through the nipper, to be coiled away in the yarn-house, and there properly hardened before it is used; otherwise it will kink, *i. e.* twist or curl, by being twisted too hard in closing. Another capstern, or crab, is fixed at the lower end of the walk, for stretching the yarn to its fullest extent, before it is worked into strands, by means of the tackle-fall, led from the sledge to the capstern; these being about eighteen yards distant from each other. The crank-wheel, which is used for spinning of lines, box-cord, &c. is fixed on an iron spindle or axis, with a handle by which to turn it. It hangs between two posts, and in its upper part, above the wheel, is let in a semicircular board to receive three sets of whirl-bolts, with wheels upon them, on which the spinners hang their threads: at the front side of the wheel is a short post, supported by a knee of oak, on which the spindle rests. The *drags* resemble the hinder part of the sledge, to which they are fastened by ropes, and they are lined with a board on the upper side: their weight serves as a press, when the rope requires more than the sledge can carry properly to stretch the strands, and prevent their kinking. The *hatchel* serves to clear the ends of the hemp, by drawing it through, having forty sharp-pointed iron-teeth, similar to the hatchel in the *clearer*, which has finer teeth. Iron-jacks are sometimes used instead of the table-wheel or back-frame wheel, and differ from the latter by having an iron-wheel with cogs, which work in the whirls, that have likewise iron-cogs. The *loper*, which is used to lay lines, has two iron swivel-hooks (running round in a brass or iron box) at each end, for the line to hang on and work, by the power of the fore-turn, from the wheel at the upper end. The *nipper* is formed of two steel-plates, with a semi-oval hole in each, which, by the motion of the upper plate, enlarges or contracts as the tarring of the yarn requires. It is thus fixed: a post is placed between the kettle and the capstern, with a mortise cut eighteen inches long from the kettle's surface, and five inches wide. The under plate is turned up on each side, to form two grooves, and is let into the front side of the post from the lower part of the mortise. The upper plate has a dove-tail on the back, that slides up and down in a groove into the grooves of the lower plate; and by a staff, made fast to its front, it is raised or lowered, and regulated by a weight suspended at the other end, so that the yarn receives no more tar than is required, and that which is squeezed out drops into a trough, and returns into the kettle. *Press-barrels* are old tar-barrels filled with clay, and laid on the sledge or drag to add weight when the rope is closing. The *reaching-post* is a post in the ground at the lower end of the walk; used in stretching the yarn by means of a tackle, one of the blocks of which is hooked to a strap round the post, the other block to a pendant at the sledge, being about eighteen yards distant from each other. *Sledges* are frames made of strong oak, clamped with iron in different parts; the two sides are the length of the sledge, made of oak, and tied in with oak bars at each end; near the front are two uprights, let into the sides, and supported by two slanting pieces from the upper end. A breast-board is fastened with iron pins to the uprights, and contains holes for the hooks to pass through, on which the books are hung; which, being turned by men, is twisted into rope, and so closed or finished. These sledges are loaded as the occasion of making the rope requires. The *spinning-wheel* is hung between two posts fixed

fixed in the ground; over its top is a femicircular frame, called the head, which contains twelve whirls, if it be for twelve spinners to spin at the same time; these whirls turn on iron spindles, with hooks to their front ends to hang the hemp on, and are worked by means of a leather band encircling the wheels and whirls. The tools and terms appropriate to rope-making are described in their proper places.

**ROPE-Yarn**, the yarn of any rope untwisted. It commonly consists of cable-ends which are worn out; and are called *junks of the cables*. It serves for many purposes among the sailors.

Rope-yarn properly denotes the smallest and simplest part of any rope, being one of the threads of which a strand is composed; so that the size of the latter, and of the rope into which it is twisted, are determined by the number of rope-yarns.

**ROPES, Standing**, in a *Ship*, the shrouds and stays are so called, because they are not removed, unless to be eased or set taught. See **SHROUDS**, and **STAYS**.

**ROPES, Staple**, ropes made of hemp, not inferior to clean Petersburg.

**ROPE-Bands**, braided cordage, used to fasten the heads of sails to their respective yards. See **ROBBINS**.

**ROPE-Deck**. See **DECK**.

**ROPE**, in *Agriculture*, a thick sort of cord formed of hemp, or other material; much used by farmers. See **CORDAGE**.

A very useful sort of rope for traces, and other similar purposes, has lately been formed of the coarse wool of sheep.

**ROPE, Cart**, that sort of rope used in loading hay, straw, or other bulky loads, by the farmer. These ropes should always be strong, and formed of the best materials, whatever the nature of them may be.

**ROPE** is also a word signifying to tedder, as a horse, or other animal. It is a very injudicious practice, and one which should by no means be generally followed by farmers.

**ROPE, Cord**, or *Strap*, in the *Manege*, is any of these tied round a pillar, to which the horse is fastened, when they begin to quicken, and supple, to teach him to fly from the chambrier, and not gallop fastly or incomparably.

In those maneges where there is no pillar, a man stands in the centre of the ground, and holds the end of the rope.

**ROPES, Drag**, in the *Artillery*, are those by which the soldiers pull the guns backwards and forwards both in their exercise, and in an engagement. They are of various lengths and dimensions, as they are used for guns or howitzers of different weights.

**ROPES, Foot**. See **FOOT-Ropes**.

**ROPES of two Pillars**, are the ropes or reins of a cavesson, used to a horse that works between two pillars. See **PILLAR**.

**ROPE-Dancer**. See **DANCER**, and **NUSANCE**.

**ROPE of Sand**, a phrase familiarly used to denote disunion, or want of adhesion and continuity. In this sense it is applicable to a variety of cases, and in military language to the disagreement that subsists between the colonel and the captains of a regiment.

**ROPE Machine for raising Water**, in *Hydraulics*.—If a vertical grooved wheel, fixed in a frame, be situated within the water at the bottom of a well, and another similar wheel, having a handle affixed to its axis, be situated in another frame at the upper part of the well; also an endless rope (*viz.* a rope whose two extremities are spliced into each other) be passed round both wheels; then, on turning the handle, the wheels and the rope will be caused to move,

*viz.* the rope will ascend on one side, and will descend on the other, passing successively through the water of the well; but the ascending part will carry up a quantity of water adhering to its surface; and this water differs in quantity, according to the size of the rope, the depth of the well, and the quickness of the motion; *viz.* with a larger rope, in a less deep well and quickest motion, a greater quantity of water will be raised, than otherwise.

In order to intercept the water at the top of the well, the upper wheel is inclosed in a pretty large box, in the bottom of which there are two holes, through which the ascending and descending parts of the rope pass. To these holes are affixed two short tubes, which prevent the exit of the water which falls to the bottom of the box. There is also a lateral spout on the side of the box, close to the bottom, for the water to come out of; and on the broad sides of the box there are two holes for the axis of the wheel. The 9th and 10th figures of *Plate XIV. Hydraulics*, exhibit a section and a front view of a machine of this sort, which was put up in the year 1782, on the castle hill at Windfor, where the depth of the well is 95 feet. A similar machine was also placed on the round tower of Windfor castle, which draws the water from the depth of 178 feet.

The same letters refer to the like parts in both figures.

The wheel, H, at the bottom of the well is of lignum vitæ, one foot in diameter. Its axis is of steel, and turns with its extremities in sockets of bell-metal.

The frame, I I, is of iron.

The wheel, E E, at the top of the well is of iron; but its rim, with the groove which receives the rope, are of lead. The diameter of this wheel is three feet.

The axis, d d, is of steel, and its extremities turn in bell-metal sockets, which are fixed in two upright posts, A, A, that support the machine. T is the handle affixed to the axis, which handle describes a circle of 28 inches in diameter; b b is the wooden box, lined with lead, which incloses the wheel E. F, F, are the holes at the bottom of the box through which the rope passes. Their diameter is about two inches.

On the same axis, d d, another wheel, C C, of about four feet in diameter, is fixed. This wheel is of wood, loaded on the edge with lead, and it serves as a fly to facilitate the motion.

The rope is of horse-hair, and measures half an inch in diameter.

With this identical machine, several experiments were tried, the result of which is as follows:

When the machine was worked slowly, *viz.* so as to make about 30 revolutions of the handle in one minute, then very little water came up adhering to the rope; and of this water a very small portion was separated from the rope within the box, so as to come out of the spout Z, in the side of the box.

When the revolutions of the handle were about 50 in a minute, then a considerable quantity of water came up adhering to the rope; and on turning the wheel E E round, the greatest part of that water, having acquired a considerable velocity, flew off in a tangent from the rope, and formed a jet within the box. This water, falling to the bottom of the box, came out of the spout Z.

It was found, that the utmost exertion of an ordinary working man could not make more than 60 revolutions of the handle in a minute; in which case the rope moved at the rate of about 16 feet *per second*. With this velocity the quantity of water that came out of the spout, Z, was about six gallons *per minute*: but it would have been impossible

possible for the man to have worked at that rate for more than three or four minutes.

This machine may evidently be placed afloat, *viz.* so as to convey the water from one place to another, which is not quite perpendicularly over the former. The same construction, and almost the same expence, will adapt the machine to wells of different depths, though the effects will not be always the same.

More than one rope, or a broad band instead of a rope, might be adapted to this machine, for which purpose, the wheels must have more than one (or a broad) groove, &c.

The greatest disadvantage of this machine is, that the rope does not last long. Its being always wet destroys it very soon. In putting on the rope, care must be had to make it well in water before it be spliced; otherwise it will either be too tight, or it will break. A hair rope has been found to last longer than one of hemp. See Cavallo's *Elem. of Nat. and Exp. Philosophy*, vol. ii.

ROPI, in *Geography*, a town of South America, in the jurisdiction of Guamanga.

ROPITZ. See REPITZ.

ROPOUREA, in *Botany*. See CAMAX.

ROPPE, in *Geography*, a town of the Tyrol; 4 miles S.W. of Stams.

ROQUE, JOHN DE LA, in *Biography*, a writer of voyages and travels, was the son of a merchant at Marseilles. He studied in his native city, and afterwards travelled into the East, but in what capacity is not known. In 1689 he visited Syria, mount Lebanon, and other countries in the East. In 1715 he was a resident in Paris, and was there associated with his brother in publishing the "Mercur de France." He died in 1745, in his 84th year. The following is a list of his principal publications: "Voyage de l'Arabie Heureuse par l'Océan oriental et le détroit de la Mer Rouge, fait par les François, &c. avec un Mémoire concernant l'Arbre du Café," 1716. "Voyage de la Palestine, fait par l'Ordre de Louis XIV." 1717: to this is annexed a translation of Abulfeda's Description of Arabia. "Voyage de Syrie et du Mont Liban, &c. avec un Abrégé de la Vie de M. M. de Chateuil," 2 vols. He was a member of the Royal Academy of Belles Lettres at Marseilles.

ROQUE, La, in *Geography*, a town of France, in the department of the Var; 6 miles S.W. of Brignoles.

ROQUE, Cape, a cape on the coast of Brasil. S. lat. 5°. W. long. 35° 40'.

ROQUEBROUE, LA, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Aurillac; 12 miles W. of Aurillac. The place contains 1277, and the canton 9812 inhabitants, on a territory of 310 kilometres, in 15 communes.

ROQUEBRUSSE, LA, a town of France, in the department of the Var, and chief place of a canton, in the district of Brignoles. The place contains 1436, and the canton 5220 inhabitants, on a territory of 187½ kilometres, in 8 communes.

ROUECOR, a town of France, in the department of the Lot and Garonne; 7 miles N.E. of Agen.

ROQUE-COURBE, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Castres; 4 miles N.N.E. of Castres. The place contains 1294, and the canton 3829 inhabitants, on a territory of 132½ kilometres, in 6 communes.

ROQUEFEUIL, a town of France, in the department of the Aude; 15 miles S.W. of Alet.

ROQUEFORT, a town of France, in the department of the Aude, and chief place of a canton, in the district of

Limoux; 7 miles S. of Quellan. The place contains 567, and the canton 4920 inhabitants, on a territory of 322½ kilometres, in 13 communes.—Also, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marfais; 12 miles N.E. of Mont-de-Marfais. The place contains 1077, and the canton 8380 inhabitants, on a territory of 565 kilometres, in 14 communes.

ROQUELAURE, a town of France, in the department of the Gers; 3 miles from Auch.

ROQUE-LIMBAUT, LA. See ROQUETAIMBAUT.

ROQUEMADOUR, a town of France, in the department of the Dordogne; 12 miles S.E. of Sarlat.

ROQUEMAURE, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzès, on the W. side of the Rhone; 6 miles N. of Avignon.

ROQUE-D'OLMES, a town of France, in the department of the Arrière; 7 miles S. of Mirepoix.

ROQUEPIC, an island in the Indian sea, covered with cocoa and other trees, flowers, and odoriferous plants. N. lat. 9° 56'. E. long. 95° 14'.

ROQUES, PETER, in *Biography*, a French Protestant divine in the 18th century, was born at Caune, in Upper Languedoc, in 1685. Having been educated for the ministry, he was chosen, at the age of 25, pastor of the French Protestant church at Basle, in connection with which he spent the remainder of his life. He died in 1748, at the age of 63. He was author of many works, which bore testimony to his learning, and the excellence of his judgment: of these, the principal are, "A Picture of the Behaviour of a Christian;" "The Evangelical Pastor;" "Elements of the Historical, Dogmatic, and Moral Truths contained in the Sacred Scriptures." He was the author of numerous papers inserted in the "Journal Helvétique," and "Bibliothèque Germanique."

ROQUESTARON, in *Geography*, a town of France, in the department of the Maritime Alps, in the district of Puget-Théniers. The place contains 344, and the canton 2224 inhabitants, on a territory of 217½ kilometres, in 7 communes.

ROQUET, in *Zoology*, the name of a species of American lizard, of small size, and of a reddish-brown colour, variegated with black and yellow spots. Its fore-legs are remarkably long for a creature of this kind; its eyes are particularly vivid and sparkling, and its head is carried continually erect; and the creature is almost always in motion, hopping about like a bird, and it usually carries its tail bent into a semicircle over the back. It is far from being shy or timorous, and is delighted at the sight of men; when tired with play or with running, it will open its mouth and pant, and loll out its tongue as the dogs do.

ROQUETAIMBAUT, in *Geography*, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen; seven miles N.E. of Agen. The place contains 1294, and the canton 5494 inhabitants, on a territory of 87½ kilometres, in 10 communes.

ROQUETAS, a town of Spain, in the province of Grenada, on the coast of the Mediterranean; 10 miles S.W. of Almeria.

ROQUEVAIRE, a town of France, in the department of the Mouths of the Rhone, and chief place of a canton, in the district of Marseilles; 12 miles E.N.E. of Marseilles. The place contains 3182, and the canton 17,926 inhabitants, on a territory of 275 kilometres, in 10 communes.

**ROQUILLE**, a measure of capacity in the West Indies; thus, the English gallon is divided into two pots, four pintes, eight chopines, sixteen roquilles, thirty-two muces, or sixty-four demi-muces.

**ROQUITE**, in *Geography*, a river of Africa, which runs into the Atlantic; 70 miles S.E. of cape Bajador.

**ROR**, a town of Bavaria; four miles S.W. of Abensperg.

**RORAAS**, a town of Norway, in the province of Drontheim; near which is a large copper mine, discovered in the year 1644; 68 miles S.S.E. of Drontheim. This mine is in the southern slope of the chain of Dofra, in a rock of what the Germans call horn-schiffer, or horn-blende slate. The veins are from six inches to six ells in thickness; and the ore of a pale yellow. The mines of Roraas are very productive, and a source of considerable revenue.

**RORARIUS, JEROME**, in *Biography*, who flourished about the middle of the 16th century, was a native of Pordenonè, in Italy, and in the course of time he became nuncio from pope Clement VII. at the court of Ferdinand, king of Hungary. He was author of a curious work, entitled "Quod animalia Bruta Ratione utantur melius Homine," in which he undertakes to shew, not only that beasts are rational creatures, but also that they make a better use of their reason than man. This work, after lying concealed in the obscure recesses of libraries 100 years, was published by M. Naude at Paris in 1645. Bayle.

**RORBACH**, in *Geography*, a town of Austria; 18 miles W. of Freyllatt.—Also, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Sarreguemines; six miles W. of Bitche. The place contains 655, and the canton 10,280 inhabitants, on a territory of 187½ kilometres, in 20 communes.—Also, a town of Germany, in the principality of Culmbach; seven miles S.S.E. of Gemunden.

**RORE**, in *Biography*. See CIPRIANO.

**RORENTZBERG**, in *Geography*, a mountain of Germany, on the Brisgau; two miles S. of Triberg.

**RORHAW**, a town of Austria; eight miles W.S.W. of Hainburg.

**RORICHE**, a river of Brandenburg, which runs into the Oder; three miles N.W. of Königsberg.

**RORIDULA**, in *Botany, from *roridus*, moist with dew, in allusion to the glandular moisture which clothes its herbage, like that of *Drosera*, the Sun-dew.—Linn. Gen. 567. Schreb. 157. Willd. Sp. Pl. v. 1. 1184. Mart. Mill. Dict. v. 4. Juss. 426. Lamarck Illustr. t. 141. Gært. t. 62.—Class and order, *Pentandria Monogynia*. Nat. Ord. uncertain, Juss.*

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, equal, permanent leaves. *Cor.* Petals five, ovate-oblong, equal, larger than the calyx. *Stam.* Filaments five, awl-shaped, half the length of the corolla; anthers inserted a little above their base, oblong, of two parallel, nearly cylindrical lobes, opening obliquely at the top, and separated almost half way down; their base pouch-like, projecting downwards, termed by Linnæus the nectary. *Pist.* Germen superior, oblong; style thread-shaped, the length of the stamens; stigma abrupt, slightly three-lobed. *Peric.* Capsule oblong, triangular, of three cells and three valves, the partitions contrary to the valves. *Seeds* solitary, oval, angular at one side, minutely dotted in rows.

Ess. Ch. Corolla of five petals. Calyx of five leaves. Anthers with a pouch at the base. Capsule of three valves and three cells. Seeds solitary.

Obs. Linnæus describes numerous seeds, but Gærtner

and Jussieu found them solitary in each cell. There is no reason to suppose these writers did not examine the very identical species.

1. *R. dentata*. Linn. Gen. Pl. 567. Syst. Veg. ed. 14. 244. Willd. n. 1. (*R. muscicapa*; Gært. v. 1. 298. *Ireon verticillata*; Burm. Prodr. Cap. 6.)—Native of bogs at the Cape of Good Hope, but apparently either in some remote tract, or not of frequent occurrence. The stem is shrubby, branched, round, smooth, purplish. Leaves numerous, crowded about the ends of the lateral shoots, linear-lanceolate, pointed, about two inches long, finely downy, deeply pinnatifid, or pectinate; their segments awl-shaped, fringed with glandular-tipped bristles. Flower-stalks first terminal, then lateral, solitary, racemose, woolly, longer than the leaves, each bearing about four large and handsome flowers. Bractæas and calyx fringed like the leaves. The petals seem to be white, or bluish-coloured. This is a very fine and singular plant, with which it is pity we are not acquainted in a recent state. May it not be allied to Jullien's *Tiliaceæ*?

**RORIFEROUS DUCT**, *q. d. dew dropping-pipe*; a name given by some to the thoracic duct; from its slow manner of conveying, and, as it were, distilling, the chyle into the common stream of blood.

**RORIPA**, or **RORIPPA**, in *Botany*, Scop. Carn. ed. 1. 520. Adanson Fam. v. 2. 417, a name which Scopoli says he borrowed from Gesner, and by which he designated a genus, which he separated from *Sisymbrium*, on account of its coloured calyx, four converging glands, and short pods. The same author, in his second edition of *Flora Carniolica*, reduces this genus, as most others have done, to *SISYMBRIUM*; see that article.

**RORNACH**, in *Geography*, a town of the bishopric of Passau; two miles N. of Passau.

**RORSBACH**, a town of the Helvetic republic, belonging to the abbey of St. Gall; six miles N.E. of St. Gall.

**RORSHEIM**, a town of Westphalia, in the principality of Halberstadt; six miles N.E. of Otterwick.

**ROS, DEW**. See DEW.

**Ros Solis**, in *Botany*, Sun Dew, a plant so called from the clear drops of viscid moisture, standing on the bristles which clothe its foliage; most abundant and conspicuous in hot bright weather. See *DROSER*.

**Ros Vitrioli**, among *Chemists*, is sometimes used for the first phlegm distilled from vitriol in balneo Mariae.

**Ros sur Couesnon**, in *Geography*, a town of France, in the department of the Ille and Vilaine; seven miles E.N.E. of Dol.

**ROSA**, in *Botany*, an ancient and popular name, derived, with most probability, from the Celtic, *rôs* or *rhos*; whence comes also its Greek synonym, *ῥοσ*; and the name of the same flower in various modern languages, Rose, Rofa, &c. De Theis remarks, that the Celtic *rhoad*, or *rhudd*, red, is the primary root of these words, the rose colour being almost synonymous with redness. Hence also came *Rhus*, *Rubus*, *Rubus*, and the Greek name of the Pomegranate, *ῥοα*, or *ῥοδία*, still in use. All these words have a manifest reference to a red colour, in some part of each of the plants.—Linn. Gen. 254. Schreb. 341. Willd. Sp. Pl. v. 2. 1063. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 537. Prodr. Fl. Græc. Sibth. v. 1. 347. Ait. Hort. Kew. v. 3. 257. Pursh 344. Juss. 335. Lamarck Illustr. t. 440. Gært. t. 73. Class and order, *Icosandria Polygynia*. Nat. Ord. *Senticosæ*, Linn. *Rosaceæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf; tube swelling, ovate or globose, contracted at the top; limb spreading, in five deep,

deep, converging, long, narrow-lanceolate segments, two of which are usually fringed, at both edges, with unequal leafy appendages, the third at one edge only, the two remaining having both edges naked; in some species all are simple and naked. *Cor.* Petals five, inversely heart-shaped, the length of the calyx, and inserted into its neck. *Stam.* Filaments very numerous, capillary, short, inserted into the neck of the calyx; anthers roundish-triangular. *Pist.* Germens numerous, in the cavity of the calyx; styles as many, villous, very short, inserted laterally into each germen, and closely compressed by the neck of the calyx; stigmas obtuse. *Peric.* none, except a spurious berry, formed of the turbinate tube of the calyx become soft and coloured, of one cell, contracted and closed at the neck, crowned with the faded hardened segments of the limb. *Seeds* numerous, oblong, hard, angular, hispid, lining the interior surface of the calyx.

*Ess. Ch.* Petals five. Calyx urceolate, five-cleft, fleshy, contracted at the neck. Seeds numerous, hispid, lining the inside of the calyx.

No genus more natural than this, in habit, or technical characters, can possibly be found. The Rose is also the most favourite of plants in all countries of the globe, the type of beauty and love, bestowing its name to enrich other flowers, which derive from thence their chief celebrity, and taking unquestioned precedence in all matters of ornament or taste. But thorns are proverbially the accompaniments of roses; nor can any one be more sensible of this, than the botanist, who attempts to extricate and define the species of this beautiful family. Cultivated plants in general are known to sport in luxuriant varieties, often transient indeed, but sufficiently durable to cause much perplexity to the accurate observer. No wonder therefore that roses, so abundant in every garden, should assume various aspects from difference of soil and treatment; though less perhaps, than most other tribes, from cross impregnation. The habit of this genus is invariably shrubby, and almost universally prickly; the branches round; leaves alternate, pinnate with an odd leaflet, serrated, frequently prickly or glandular; one species only being known to have simple leaves, or, in other words, to want the lateral leaflets. Stipulas almost always united to the base of the common footstalk. Flowers terminal, stalked, usually red, variously and deliciously fragrant; sometimes white; very rarely yellow, and in that case either inodorous or fœtid. Fruit harmless, but seldom pleasant. Seeds slow in germination.

The generality of writers on Roses have come under the description of florists rather than botanists, and their figures have been executed accordingly. Linnæus found the determination of species very difficult. Ehrhart paid considerable attention to the subject, and in his *Beiträge* has thrown much light upon it, by which Willdenow has profited. The garden Roses are well arranged in the new edition of Aiton's *Hortus Kewensis*, where we shall find but little to improve or correct; and they are elegantly displayed in Miss Lawrence's ample collection of figures, published in 1799, except that we could have wished for much more delicacy, and discrimination of tints, in their various foliage. Several new British ones have been first described, by the writer of the present article, in *English Botany*, where Mr. Sowerby has, as usual, been happy in his representations of their distinctive habits and characters.

The species are distributed by Linnæus, and all his followers, into two sections, distinguished by the shape of the tube of the calyx, inaccurately termed by him the germen. Of this error Willdenow takes notice, without correcting it, not being at that time aware of the measure adopted in

our *Flora Britannica*, where, by substituting *fruit* for *germen*, every inconvenience and inaccuracy is avoided. Mr. Dryander and Mr. Aiton in *Hort. Kew.*, while they follow, as we shall here do, Willdenow's general and particular distribution of the species, have, in the point just mentioned, corrected his phraseology. Our new species, chiefly supplied by English Botany, and Pursh's *Flora of North America*, will be inserted, as nearly as possible, according to their affinities. Perhaps some of the old ones might have been better placed; but except any glaring impropriety presented itself, more inconvenience than benefit would arise from disturbing an arrangement so generally received, and which Linnæus first formed in his *Systema Naturæ*, ed. 12. We have only brought *canina* and its allies nearer together than they are placed in the above-mentioned books.

Section 1. *Fruit nearly globose.*

1. *R. berberifolia.* Barberry-leaved Rose. "Pallas in *Nov. Act. Petrop.* v. 10. 379. t. 10. f. 5." Willd. n. 1. Ait. n. 1. (*R. simplicifolia*; *Salis. Hort.* 359. *Parad.* t. 101. *Poiret in Lamarck Dict.* v. 6. 276.)—Fruit globose, prickly, as well as the flower-stalk. Leaves simple, nearly sessile, with stipular recurved prickles. Found by Michaux and Olivier in the north of Persia. Seeds sent by the former to sir J. Banks were raised at Kew about the year 1790, but the plants did not long survive. This species is extremely remarkable for its simple leaves, which are obovate, glaucous, coarsely serrated, about an inch long, smooth, on short stalks, without stipulas, but having in their stead a pair of recurved taper prickles, spreading from the base of each footstalk. The branches are also beset with shorter prickles. *Flowers* solitary, on short, terminal, prickly, downy stalks. *Petals* yellow, crimson at the base. *Fruit* globular, very prickly, crowned with the simple narrow segments of the calyx. We wish the name *simplicifolia* had been retained, as much the best; and if Jusseu had actually given it as a name, in his *Gen. Pl.* 452, it might, by the right of priority, have superseded Pallas's appellation.

2. *R. lutea.* Yellow Sweet-briar. *Mill. Dict.* ed. 8. n. 11. Willd. n. 2. Ait. n. 2. *Curt. Lond.* t. 363. *Lavr. Ros.* t. 12. *Lob. Ic.* v. 2. 209. *Ger. Em.* 1267. (*R. lutea simplex*; *Bauh. Pin.* 483. *R. Eglanteria*; *Linn. Sp. Pl.* 703. *R. chlorophylla unicolor*; *Ehrh. Beitr.* v. 2. 70. *Arb.* 156. *R. fœtida*; *Herm. Ros.* 18. *Allion. Ped.* v. 2. 138.)

*β. bicolor.* Austrian Rose, or Copper Sweet-briar; *Jacq. Hort. Vind.* v. 1. t. 1. *Curt. Mag.* t. 1077. *Lavr. Ros.* t. 6. (*R. sylvestris austriaca, flore phœniceo*; *Hort. Angl.* 66. t. 18.)—Fruit globose, smooth, as well as the flower-stalk. Calyx and leaf-stalks minutely prickly. Prickles of the branches straight. Leaflets obovate, doubly serrated, rather glutinous, smooth.—Native of Germany and Italy; but not, as Willdenow reports, of England. It is however frequent here in old country gardens, in a pure air, flowering in June. Gerarde cultivated this species, and even raised it from seed, in order to refute a vulgar error, of its being some common rose, turned yellow by grafting on a broom-stock. The beautiful red or copper-coloured variety, *β*, is more difficult of cultivation, especially with respect to air. The stem is bushy, four or five feet high. Leaves deciduous, of five or seven obovate, strongly serrated, deep green, shining leaflets, rather viscid to the touch, and exhaling a most sweet and peculiar aromatic odour, more grateful to us than that of the Common Sweet-briar. *Flowers* copious, large, usually of an uniform golden yellow, with the smell of bugs; but in the variety *β* the upper side of the petals is of a tawny red, and the disagreeable

agreeable odour is less. We have, under the article EGLANTERIA, given the history of Linnæus's mistake, in confounding the present species, first with the Common Sweetbriar, and then with the Double Oriental Yellow Rose, (see hereafter *R. sulphurea* and *R. rubiginosa*); as well as our reasons for following the Hort. Kew., Willdenow, &c. in these names. The fruit of *R. lutea* has never been seen or heard of by us, in a state of maturity.

3. *R. sulphurea*. Double Yellow Rose. Ait. Hort. Kew. ed. 1. n. 2. ed. 2. n. 3. Willd. n. 3. Lawr. Ros. t. 77. (*R. glaucophylla*; Ehrh. Beitr. v. 2. 69. *R. hemisphærica*; Herm. Ros. 18. *R. lutea multiplex*; Ger. Em. 1267. Hort. Angl. 66. t. 18. *R. lutea maxima*, flore pleno; Hort. Eyf. vern. ord. 6. t. 2. f. 4. *R. flava*, flore pleno; Cluf. Cur. Post. 6.)—Fruit globose, somewhat prickly. Flower-stalks smooth. Stem with two sets of copious straight prickles. Stipulas jagged. Leaflets obovate, simply ferrated, glaucous, smooth. This fine and singular species, strangely confounded, by many botanists, with the last, was received by Clufius from the Levant, but its native country is not precisely known. It has been cultivated in England for near 200 years, and is perfectly hardy as to cold, but very impatient of low, confined, or smoky situations; nor does it, in the most favourable, often expand its copious and truly glorious flowers to advantage. We have seen them in the greatest perfection, on a poor gravelly soil, exposed to east winds, about outhouses and hovels, where no care was taken of the plant. The bush is larger than *R. lutea*, and evidently distinguishable by the pale glaucous hue of its smooth inodorous leaves. The prickles of the stem are of two kinds; some twice as large as the others. Flowers large and very double, without scent, of a rich but delicate golden yellow; their inner petals, when perfect, so profusely and elegantly crumpled, and so brightly transparent, that neither the structure, nor the colour, of any other rose, can give the slightest idea of their beauty; much less has any artist, except perhaps Van Huysum, in one or two of his finest pictures, done this flower tolerable justice. The foliage in Miss Lawrance's plate is much too dark, and wants the glaucous pale aspect which characterizes the species. The flower is well drawn in the old Hortus Eystetenensis.

4. *R. Banksiæ*. Lady Banks's Rose. Ait. n. 4.—“Smooth, naked, and without prickles. Fruit globose. Leaves ternate or pinnate, shining. Stipulas fetaceous, distinct.”—Native of China, from whence it is said to have been brought, by Mr. W. Kerr, in 1807. It is marked, by Mr. Aiton, as a green-house shrub, blossoming in June and July. We have seen neither specimen nor figure.

5. *R. blanda*. Labrador, or Hudson's bay, Rose. Ait. Hort. Kew. ed. 1. n. 3. ed. 2. n. 5. Willd. n. 4. Pursh n. 1. Lawr. Ros. t. 27.—Fruit globose, smooth. Adult stems, like the flower-stalks, quite smooth, and without prickles.—Native of the most northern parts of America, on the east, as well as west, coasts, flowering there, as in our gardens, from May to August. Mr. Gordon is known to have cultivated it in 1773, but the species has not excited general notice. The young branches, and their leaf-stalks, bear copious, straight, red prickles, but they afterwards become smooth, naked, red and shining. The leaflets are usually seven, oblong, or obovate, large, varying in breadth. Stipulas broad and long, with glandular spreading points. Flowers solitary, moderately large, crimson. Tube of the calyx short, and almost hemispherical; segments long and simple, tapering gradually to a point.

6. *R. cinnamomea*. Cinnamon Rose. Linn. Sp. Pl. 703. Willd. n. 5. Ait. n. 6. Engl. Bot. t. 2388. Ger. Em.

1268. Lawr. Ros. t. 34. (*R. fluvialis*; Fl. Dan. t. 868. Retz. Scand. ed. 2. 120. *R. majalis*; Herm. Ros. 8. Rosier printanier; Reynier Mém. de la Suisse, v. 1. 222.)  
β. *R. collincola*; Ehrh. Beitr. v. 2. 70. Arb. 25.

Fruit globose, smooth as well as the flower-stalks. Stem with occasional, small, twin prickles, below the stipulas. Footstalks scarcely prickly. Leaflets oblong, finely downy, glaucous beneath.—Native of Germany, Switzerland, Sweden, and Denmark; first observed wild in England by Mr. Salisbury, in the wood in Aketon pasture, near Pontefract, Yorkshire. In gardens the double variety is common. This is one of our earliest Roses, flowering in May. The bush is rather tall, with brown or reddish twigs, shining and smooth, except the small, and not universal, twin prickles, under each stipula. The leaves have a dull glaucous aspect, and are usually elliptic-oblong, unequally ferrated; in β, Ehrhart's *collincola*, which our friend Dr. Afzelius is inclined to make a distinct species, they are broader and more obtuse, but we can find no permanent specific mark. Still less can we distinguish, even as a variety, the *fluvialis* of Fl. Dan. The flowers are of a delicate purplish blush-colour, at least such are the double ones, seen in gardens; in which we could never detect any of the cinnamon scent, mentioned by Bauhin, to justify the name. The fruit of the wild kind is small, globose, scarlet. Segments of the calyx simple, long, and slender, for the most part slightly spatulate at the end, but not invariably so. The bush, when young, is sometimes very prickly.

7. *R. kamtschatica*. Kamtschatka Rose. Venten. Hort. Cels. t. 67, not 68. Ait. n. 7.—Fruit globose, smooth as well as the flower-stalks. Stem downy, very prickly. Leaf-stalks somewhat prickly. Leaflets obovate, abrupt.—Native of Kamtschatka.—Sent to Kew by M. Cels, from his garden at Paris, in 1802; but it was, long before, cultivated in Chelsea garden, from whence we received a specimen in 1791. Every part is larger than the preceding. The stem is downy, and armed with numerous, scattered, straight, pale, slender prickles; some of which are also found on the leaf-stalks. Leaflets usually seven, of a pale glaucous green, veiny and rugged; somewhat downy beneath; coarsely ferrated, abrupt and emarginate. Stipulas obovate, dilated, obtuse, veiny and downy. Flowers solitary, purplish rose-coloured, fragrant. Segments of the calyx simple, entire, spatulate at the ends. Fruit small, globose, red. Perhaps this species ought to have been introduced between *blanda* and *cinnamomea*.

8. *R. arvensis*. White Dog Rose. Hudf. Angl. ed. 1. 192. Linn. Mant. 2. 245. Willd. n. 6. Ait. n. 8. Fl. Brit. n. 2. Engl. Bot. t. 188. Lawr. Ros. t. 86. (*R. fylvestris*; Herm. Ros. 10. *R. Herporhodon*; Ehrh. Beitr. v. 2. 71. *R. ferpens*; Ehrh. Arb. 35. *R. fylvestris folio glabro*, flore planè albo; Bauh. Hist. v. 2. 44.)—Fruit nearly globose, smooth. Flower-stalks glandular, somewhat cymose. Prickles of the stem and leaf-stalks hooked. Styles elongated, combined.—Native of England, Germany, and Switzerland. It often decorates, in profusion, the hedges and thickets of the gravelly counties of England, flowering in June and July, when its long, trailing, purplish-brown twigs, and copious milk-white blossoms, are highly ornamental. We believe this species is unknown in Sweden and Denmark; for the t. 398 of Fl. Dan. cited by Linnæus, whom Willdenow like Hudson copies, is most evidently, as it calls itself, *spinosissima*. There is a glaucous hue on the young shoots, as well as on the backs of the leaflets, which are mostly five, oval, pointed, smooth, with sharp unequal ferratures. Stipulas linear, pointed. Flower-stalks rough with glandular bristles, not prickly. Base of the calyx smooth and ovate,

but the fruit is globose, of a deep red, crowned with the elongated styles, so combined as to seem one.

9. *R. spinosissima*. Burnet Rose. Linn. Sp. Pl. ed. 1. 491. ed. 2. 705? Willd. n. 8. Ait. n. 9. Fl. Brit. n. 1. Engl. Bot. t. 187. Fl. Dan. t. 398. Lawr. Ros. t. 48 and t. 78. Ehrh. Arb. 85. (*R. pimpinellifolia*; Linn. Syst. Nat. ed. 10. 1062. Sp. Pl. 703. R. n. 1106; Hall. Hist. v. 2. 40. *R. campestris spinosissima*, flore albo odoro; Bauh. Pin. 483. *R. campestris odora*; Clus. Pan. 111. *R. campestris odorato flore*; Clus. Hist. 116. *R. pimpinellæ folio*; Ger. Em. 1270.)—Fruit globose, smooth as well as the flower-stalks. Prickles of the stem very numerous, straight and setaceous. Leaflets roundish, smooth. Calyx of the fruit reflexed.—Native of sandy downs near the sea, as well as the borders of fields, and mountains, in various parts of Europe; not uncommon in Britain, flowering in July.—This is a bush of humble growth, seldom more than two or three feet high, and much branched. The stem is copiously clothed with innumerable, straight, crowded, needle-like, pale prickles. The leaf-stalks are occasionally prickly. Leaflets seven or nine, roundish, or slightly elliptical, obtuse, serrated, small, even and smooth, a little glaucous, not shining. Flower-stalks terminal, solitary, single-flowered, rather swelling upwards, always, as far as we have seen, smooth and naked. Germen depressed, and nearly hemispherical. Segments of the calyx tapering, smooth, and entire. Flowers with a light pleasant scent, usually cream-coloured, yellow in the middle; but Miss Lawrance's t. 78 represents the red variegated variety, first described by Sibald in his Scotia Illustrata, p. 2. 46. t. 2, under the name of *R. Ciphiana*. The fruit is much larger than the leaflets, globose, dark purple, and finally quite black, with large seeds, and crowned with the reflexed calyx.—We feel no scruple in referring the *pimpinellifolia* of Linnæus to his *spinosissima*, of which it is not even a variety; but we cannot take into consideration all the different things which various authors have supposed one or other of these species. We shall notice *pimpinellifolia* of Villars under *alpina*. Miss Lawrance's t. 15 and t. 19, are doubtful, on many accounts. The former indeed answers to our next species. Her t. 63 is surely different from both. The synonyms of old writers, regarding this Rose, are very puzzling, nor have they ever been well explained. The figure in Clusius's Stirp. Pannon. 114, belongs in truth to *spinosissima*, as he gives it in his Historia; while his 4th Rose, or *χαμαίροδο* of the former work, to which that figure seems annexed, is *pumila* of Jacquin. His other cut, at p. 111, more resembles *cinnamomea*, which is often very prickly the first season, as professor Swartz remarks. Our learned correspondent just named likewise suggests that the *cinnamomea* is one of various things which Linnæus in Fl. Suec. confounded under the name of *spinosissima*. Haller has certainly not adverted to all the Roses known to be found in Switzerland, but his n. 1106 can be no other than our *spinosissima*.

10. *R. rubella*. Red-fruited Dwarf Rose. Sm. Engl. Bot. t. 2521. (*R. spinosissima*  $\gamma$ ; Fl. Brit. 537?  $\beta$ ; Lawr. Ros. t. 15.)—Fruit globose, somewhat bristly. Flower-stalks bristly. Prickles of the stem very numerous, straight, and setaceous. Leaflets elliptical, smooth. Calyx of the fruit inflexed.—Gathered near Newcastle, by Mr. Winch. We have also specimens from Mr. James Backhouse, who has just informed us that he finds the inflexed calyx, after flowering, an invariable character of this species, that of the foregoing being always reflexed. The rough flower-stalks are less unalterable, though tolerably constant. The scarlet fruit is a very remarkable difference. The flowers are elegantly tinged with red. Mr. Backhouse thinks this rather

the taller-growing shrub of the two, and he observes that the leaves fold together, or sleep, at night. We know not whether this is the case with *spinosissima*.

11. *R. involuta*. Dr. Walker's Rose. Fl. Brit. 1398. Engl. Bot. t. 2068. Ait. n. 10.—Fruit globose, very prickly as well as the flower-stalks. Prickles of the stem very numerous, and nearly straight. Petals involute and imperfectly expanded. Leaflets elliptical, hairy beneath.—Native of the Hebrides, where it was gathered by the Rev. Dr. Walker, and Mr. J. Mackay.—The present species has the general habit, and very prickly stem, of the two last. But the flower-stalks, leaf-stalks, and young fruit, are all extremely prickly, the latter being more disposed to be ovate than depressed. The leaflets are more elliptical, their under side hairy, especially the ribs. Segments of the calyx long, simple, pointed, rough externally with glandular prickles. Petals pale blush, with deeper tints here and there, concave and involute, seldom more than half expanded. Ripe fruit unknown to us.

12. *R. parviflora*. Small American Rose. Ehrh. Beitr. v. 4. 21. Willd. n. 9. Pursh n. 2. (*R. caroliniana*; Mich. Boreal-Amer. v. 1. 295. *R. carolina*; Sm. Inf. of Georgia, v. 1. 49. t. 25.)—Fruit globose, slightly depressed, bristly as well as the flower-stalks and calyx. Leaf-stalks downy, somewhat prickly. Prickles in pairs under the stipulas, straight. Leaflets elliptic-lanceolate, simply serrated, smooth. Flowers solitary or in pairs.—“Native of woods on the sides of hills, from New York to Carolina, flowering in June and July. About two feet high. There are a number of varieties of this species.” Pursh. Our specimens, sent by the Rev. Dr. Muhlenberg, answer well to the figure above cited, and have, like that, solitary flowers, of a pale pink hue. The stem is slender and smooth, except a pair of awl-shaped, slender, straight prickles under each stipula. Leaflets five, elegantly elliptical; their common stalk reddish, channelled, prickly, somewhat downy, or hairy. The Rose in Dill. Elth. t. 245. f. 316, is exactly our's, though quoted by authors for the *lucida*.

13. *R. nitida*. Polished American Rose. “Willd. Enum. 544.” Pursh n. 3.—“Fruit globose. Calyx, flower-stalks, and branches hispid. Leaf-stalks rather downy, without prickles. Leaflets oblong-lanceolate, polished and smooth on both sides.”—In Pennsylvania and Virginia, flowering from June to August. Petals red, obovate. Leaflets seven. Pursh. We have not met with any specimen or figure.

14. *R. lucida*. Shining American Rose. Ehrh. Beitr. v. 4. 22. Arb. 76. Willd. n. 10. Pursh n. 4; excluding the synonym of Dillenius. (*R. alpina*  $\beta$ ; Ait. n. 27. Lawr. Ros. t. 75.)—Fruit globose, depressed, rather hispid as well as the flower-stalks. Leaf-stalks somewhat prickly, not downy. Prickles usually in pairs under the stipulas, straight. Leaflets ovato-lanceolate, bluntish, coarsely serrated, very smooth, shining. Corymbs of few flowers.—On the borders of swamps, from New York to Carolina, flowering in July and August. From four to six feet high. Pursh. By Ehrhart's specimen, the only one we have seen, it evidently appears, that the *R. carolina fragrans, foliis mediotenus ferratis*; Dill. Elth. 325. t. 245. f. 316, is very erroneously referred by Willdenow and Pursh to the present species; belonging, if we are right in what we take for *parviflora*, n. 12, indubitably to that plant. The present has seven leaflets, of a larger size and firmer texture. Stipular prickles shorter, thicker, not always present. Flowers corymbose, four or five together. If we are right in Miss Lawrance's figure, this species, as well as *parviflora*, ought to be placed on the list of our garden plants.

15. *R. gemella*. Twin-flowered American Rose. "Willd. Enum. 544." Pursh n. 5.—Fruit globose, smooth as well as the flower-stalks. Flowers mostly in pairs. Leaflets elliptic-oblong, opaque; their veins hairy beneath. Leaf-stalks downy. Prickles in pairs under the stipulas, hooked.—On dry sunny hills, from New England to Carolina, flowering in July and August. A low *shrub*, with large red *flowers*. Pursh. Specimens in the herbarium of Linnæus, referred by him to *R. carolina*, have slender *branches*, quite smooth, and somewhat glaucous. *Leaflets* seven, smaller, thinner, and more acutely serrated than the last; rather glaucous and downy beneath; their veins as if fringed. *Leaf-stalks* and *stipulas* finely downy and hoary. *Flowers* terminal, in pairs, on short smooth *stalks*, enveloped in large downy *bractæas*. *Germs* exactly globular, quite smooth and naked. Segments of the *calyx* smooth at the base, downy at the edges and upper part, simple; spatulate at the end.

16. *R. Lyonii*. Lyon's American Rose. Pursh n. 6.—"Fruit nearly globose, smoothish. Flower-stalks hispid, mostly ternate. Leaf-stalks rather prickly. Stem with straight scattered prickles, not hairy. Leaflets ovate-oblong, acute, serrated; smoothish above; downy beneath: the upper leaves simple. Stipulas linear. Segments of the calyx downy, linear, scarcely lacinated."—Gathered by Mr. Lyon in Tennessee, North America, flowering in July. The *leaflets* are three or five, small, with coloured veins. *Flowers* pale red. Pursh.

17. *R. fetigera*. Fringe-cupped American Rose. Mich. Boreal-Amer. v. 1. 295. Pursh n. 7.—"Fruit globose. Stalks and ribs of the leaves prickly. Branches not hairy; their prickles in pairs or scattered. Leaflets pointed, smooth. Segments of the calyx fringed with bristles."—In swamps of Virginia and Lower Carolina, flowering in June and July. From five to eight feet high. *Leaflets* three or five. Pursh.

18. *R. carolina*. Carolina Rose. Linn. Sp. Pl. 703, omitting the reference to Dillenius. Willd. n. 11. Ait. n. 11. Pursh n. 8. Lawr. Raf. t. 24. t. 3. t. 54; also perhaps t. 68, and t. 66; scarcely t. 36. (*R. corymbosa*; Ehrh. Beitr. v. 4. 21.)—Fruit globose, bristly as well as the flower-stalks. Leaf-stalks hairy, somewhat prickly. Stem smooth. Stipular prickles slightly hooked. Leaflets elliptic-lanceolate, acute, finely serrated; downy and glaucous beneath. Flowers corymbose.—In swamps, and on the banks of ponds, from New England to Virginia, flowering in June and July. Pursh says, "there are a great many varieties of this species." So little, however, have these been attended to, that five or six of those species which we have last described have, by Linnæus and others, been usually referred to *R. carolina*. The true *carolina* common in our shrubberies, flowering in June and July, is well distinguished by the above characters, first pointed out by the accurate and observing Ehrhart. This *shrub* is five or six feet high, bushy, but erect, with red, smooth, a little glaucous, twigs. *Leaflets* large, more copiously and minutely serrated than in *lucida*, n. 14, which this species, at first sight, most resembles; but they differ also from that in their glaucous and downy under side, as well as in having a fine taper point. The *flowers* are more numerous in each *corymb*, large, of a full crimson. The Pennsylvania Rose of the gardens, figured by Miss Lawrence, t. 68, and t. 66, differs in some respects from the common *carolina*. Its *leaflets* are more coarsely and sharply serrated; pale, but not glaucous nor downy, beneath. *Flowers* smaller and paler; in the double variety peculiarly beautiful, most of the outer petals being of a light flesh-colour, the central ones involute or tufted, of a rich crimson.

19. *R. rubifolia*. Bramble-leaved Rose. Ait. n. 12. Pursh n. 9.—"Fruit globose, rather hispid as well as the flower-stalks. Calyx unexpanded, pointless. Leaves ternate; downy beneath. Leaf-stalks glandular and prickly. Stem with somewhat hooked, stipular and scattered, prickles, not hairy. Flowers corymbose."—Discovered in North America, by the late Mr. Francis Maffon, who sent it to Kew in 1800. It is a hardy *shrub*, flowering in June and July, but has not yet fallen under our observation.

20. *R. villosa*. Apple Rose. Linn. Sp. Pl. 704. Willd. n. 12. Ait. n. 13. Fl. Brit. n. 3. Engl. Bot. t. 583. Lawr. Raf. t. 33, and t. 29. (*R. pomifera* major; Park. Parad. 418. f. 7.)—Fruit globose, bristly as well as the flower-stalks. Prickles of the stem nearly straight. Leaflets elliptic-oblong, downy on both sides. Segments of the calyx the length of the ripe fruit.—Native of mountainous woods and thickets, in the north of Europe. Plentiful in Westmoreland, Cumberland, and the north of Yorkshire, flowering in June. It is often cultivated in shrubberies for the sake of the beauty of its large scarlet bristly fruit, above an inch in diameter. The double-flowered variety, when luxuriant, is one of our handsomest flowering shrubs. Miss Lawrence's figures of this species are not happy. The bush is from four to six feet high, with strong, straight, scattered prickles. *Leaflets* five or seven, large, of a peculiar elliptic-oblong shape, somewhat rounded at the end, doubly serrated and glandular at the edges, finely downy and hoary on both sides, aromatic or pungent, in some degree, when rubbed. *Flowers* one or two at the end of each branch, lightly scented, of a fine pale pink. *Fruit* at every period armed with strong thorns, and crowned when ripe with the hispid, involute, twisted *calyx*, which then hardly exceeds it in length.

21. *R. mollis*. Soft-leaved Round-fruited Rose. Sm. Engl. Bot. t. 2459. (*R. villosa*  $\beta$ ; Fl. Brit. 538. Relh. Cant. 193. *R. sylvestris*, folio mollitè hirsuto, fructu rotundo glabro, calyce et pediculo hispidis; Dill. in Raii Syn. 478.)—Fruit globose, half as long as the segments of the calyx, bristly as well as the flower-stalks. Prickles of the stem straight. Leaflets elliptic-ovate, downy on both sides.—Native of bushy places, in England, Scotland, and Wales, flowering in June or July. A much more humble shrub than the *villosa*; the *leaflets* less oblong, and more ovate; *petals* of a deeper red; ripe *fruit* much smaller, purplish, not scarlet, its length or diameter not above half the length of the permanent *calyx*, one segment of which, and no more, is often very distinctly pinnated. The Rev. H. Davies has found the *fruit* variable in Anglesea, from perfect smoothness, as mentioned by Dillenius, to every degree of roughness. The prickles of the *stem* vary in size, and are frequently hooked.

22. *R. glutinosa*. Clammy Cretan Rose. Sm. Prodr. Fl. Græc. Sibth. v. 1. 348. Fl. Græc. t. 482, unpublished. (*R. cretica montana*, foliis subrotundis glutinosi et villosi; Tournef. Cor. 43. *R. pumila alpina*, pimpinellæ exacte foliis sparsis, spinis incurvis, aquatè purpurea; Cupan. Panphyl. ed. 1. v. 1. t. 61.)—Fruit globose, hispid as well as the flower-stalks. Prickles of the stem copious, hooked. Leaflets roundish; downy and glandular on both sides.—Native of the Sphaciote mountains of Crete, and, from Cupani's synonym, of the mountains of Sicily. By a specimen sent to Linnæus, the plant seems to have been cultivated in the French gardens, but we know it not in England. The *stem* is low, bushy, with numerous stout *branches*, armed with many, scattered, strong, hooked prickles. *Leaflets* seven, roundish and obtuse, strongly and

often doubly ferrated; downy, somewhat hoary, glandular and viscid on both sides, as are also the *leaf-stalks*. *Flowers* small, pale bluish, terminal, solitary, on short, brittle, viscid *stalks*. *Fruit* globose, scarlet, covered with rigid glandular-pointed bristles, its diameter full half an inch, which nearly equals the length of the permanent, upright, converging, hispid *calyx*.

23. *R. hibernica*. Irish Rose. Sm. Engl. Bot. t. 2196. Ait. n. 14.—Fruit nearly globose, smooth as well as the flower-stalks. Prickles of the stem slightly hooked. Leaflets elliptical, smooth; their ribs hairy beneath.—Discovered by John Templeton, esq. in the county of Down, about Belfast harbour, where it grows abundantly, flowering from the early part of June, till the middle of November. The discoverer thus became entitled to the liberal premium of fifty pounds, offered by the patrons of botany at Dublin, for the detection of any new Irish plant. The above characters readily distinguish this species, from every other described rose. The *stem* is six feet high, erect, much branched, and very prickly. *Leaflets* broadly ovate, deeply and acutely ferrated, smooth, except the back of their ribs and veins, which are hairy. Sometimes a few coarse hairs occur on the upper surface. *Flower-stalks* often solitary, sometimes two or three together. *Petals* pale bluish-coloured. *Fruit* scarlet, smooth, accurately globose when young, but in ripening sometimes elongated at the summit, so as to become slightly ovate.

This is not the only new Irish Rose that has been discovered of late; Dr. Taylor having favoured us with incomplete specimens of what will certainly prove two or three others, hitherto nondescript; one of them with remarkably large, twin, hooked, stipulary *prickles*, unlike any other species with which we are acquainted.

24. *R. sinica*. Three-leaved Chinese Rose. Linn. Syft. Veg. ed. 13. 394. Ait. n. 15.—“Fruit nearly globose, smooth. Flower-stalks prickly, hispid. Stem and leaf-stalks prickly. Segments of the calyx lanceolate, somewhat stalked.”—Native of China. Cultivated by Miller in 1759. A hardy shrub, flowering from May to July. Aiton. We adopt this entirely on the authority of the *Hortus Kewensis*, having never seen the garden plant; nor have we any authentic specimen to prove what *R. sinica* of Linnæus really is; he having mentioned it only, under the above characters, in his *Systema Vegetabilium*. There occurs in his herbarium, a specimen from the Upsal garden, marked *China*, which answers to the above characters; especially in the paradoxical account of the stalked leaves, or segments of the *calyx*, they being here in a deformed or monstrous state. But the leaflets are five, not three, as Mr. Aiton’s English name implies; and the very young *fruit*, though “nearly globose,” has all the appearance of being truly oval when perfectly formed. Indeed we believe this specimen to be not essentially different from *R. indica*, the Pale China Rose, now so common in gardens.

25. *R. rugosa*. Rugose Japan Rose. Thunb. Jap. 213. Willd. n. 13.—“Fruit globose, smooth. Flower-stalks, leaf-stalks, and stem prickly. Leaflets obtuse with a point, rugose, downy beneath.”—Native of Miaco in Japan, flowering in May and June, and known by the name of Ramanas.—*Stem* shrubby. *Branches* somewhat downy, armed with larger and smaller, very dense, spreading, white prickles. *Leaflets* nine, an inch long, ovate, blunt, with a point, ferrated; green and rugose above; downy, veiny and rugose beneath; their *common stalk* downy, beset with scattered, spreading, white prickles. *Flowers* solitary, on downy *stalks*, furnished also with copious, very slender, spreading, white prickles. *Calyx* downy within; hairy

without. Young *fruit* globose, destitute of prickles or pubescence. Thunberg.

26. *R. provincialis*. Provins Rose. Mill. Dict. ed. 8. n. 18. Ait. Hort. Kew. ed. 1. n. 11. ed. 2. n. 16. Willd. n. 14. Lawr. Raf. t. 8. t. 22. t. 1. t. 4. t. 43. t. 21.

β. *R. muscosa*; Ait. n. 25. Willd. n. 22. Curt. Mag. t. 69. Lawr. Raf. t. 14. (*R. rubra plena spinosissima*, pedunculo muscosa; Mill. Ic. 148. t. 221. f. 1. *R. provincialis spinosissima*, pedunculo muscosa; Hort. Angl. 66. t. 18.)

γ. Leaves and flowers much smaller. Rose de Meaux, &c.; Lawr. Raf. t. 31. t. 50. t. 71. Curt. Mag. t. 407. To which are most akin Lawr. Raf. t. 88 and t. 76; mere evanescent varieties.

Fruit roundish. Flower-stalks and leaf-stalks hispid. Prickles of the branches scattered, somewhat hooked. Leaflets roundish-ovate; hairy beneath; with glandular ferratures.—Native of the south of Europe; at least it is so considered; though a plant too generally cultivated for any thing to be averred on this subject. With us it is hardy, flowering in June and July. Most of the varieties are increased by roots or layers, and remain tolerably distinct; the different forms of variety γ are least permanent. *Stems* usually three or four feet high, straight, very prickly. *Leaflets* five, of a rounded bluntish figure, veiny and rugose. *Stipulus* linear-lanceolate, acute, undivided; most entire in their lower part. *Flowers* two or three, or more, at the top of each branch, large, delightfully fragrant, of that peculiar bright crimson hue popularly termed a rose-colour, with broad brown stains on the backs of the outer *petals*, which are permanent in the otherwise white variety, represented in Miss Lawrence’s t. 4. In all our cultivated varieties the *flowers* are double, with slight remains of *stamens* or *styles*; so that the *fruit* never ripens. We have however seen, in the ample collection of roses at Messrs. Lee and Kennedy’s, perfectly single *flowers* of the Moss Rose, which those experienced cultivators have proved to be only a variety of the Common Provins Rose. Indeed we have been told in Italy, that this variety loses its mossiness, almost immediately, in that climate.

27. *R. serax*. Hedge-hog Rose. Ait. n. 17. Lawr. Raf. t. 42.—Fruit globose, hispid. Leaflets elliptic-oblong, rugose, four pair with an odd one. Stem, leaf-stalks, and young branches, very densely spinous.—Native of mount Caucasus. Introduced about 1796, by Lee and Kennedy. Hardy, flowering from June to August.—A stout bushy *shrub*, very remarkable for its copious, long, straight prickles. The *leaflets* are recurved, convex, and rugose, of a glaucous hue. *Flowers* large, crimson, on short stalks.

Section 2. *Fruit ovate, or oblong.*

28. *R. gallica*. Red Official Rose. Linn. Sp. Pl. 704. Willd. n. 16. Ait. n. 19. Ehrh. Off. 324. Woodv. Med. Bot. t. 141. Lawr. Raf. t. 16. t. 13. t. 57. t. 7, and t. 49. (*R. rubra*; Ger. Em. 1261. Bauh. Pin. 481. Rosa; Matth. Valgr. v. 1. 168. *R. milefia rubra*, flore simplicis; Hort. Eyll. vern. ord. 6. t. 6. f. 3. *R. prænestina variegata*; ibid. t. 2. f. 2. Mill. Ic. 148. t. 221. f. 2.)

β. *R. centifolia*. Linn. Sp. Pl. 704. Willd. n. 15. Ait. n. 18. Lawr. Raf. t. 11. t. 40. t. 85. t. 44. t. 51. t. 2. t. 35. t. 46. t. 67. t. 20. t. 59. t. 47. t. 55. t. 39. t. 73. t. 82. t. 87. t. 79. t. 89. (*R. centifolia rubra*; Hort. Eyll. vern. ord. 6. t. 2. f. 1. *R. hollandica*, sine batava; Ger. Em. 1262.)

Fruit ovate, hispid as well as the flower-stalks. Stem hispid

hispid and finely prickly. Leaflets ovate; hairy beneath. Calyx half-pinnate.—Native of the southern parts of Europe. This, in its nearly single state, is the Rose always used medicinally, for conserve, tincture, &c. on account of the richer colour, and more astringent quality, of its petals. Its numerous varieties are common in gardens throughout Europe, blooming in June and July. We perfectly agree with our friend Mr. Lee of Hammer-smith, that the *R. centifolia* of authors, of which so many trifling varieties are indicated above, is itself merely a variety of the *gallica*. This a comparison of their *leaves* will readily prove. The roughness of their *leaf-stalks* is undoubtedly variable. *R. gallica* in its natural state, as it is said to be in the south of France, and as we see it usually in country gardens and shrubberies, is scarcely three feet high, throwing up, from its creeping *roots*, many *stems*, armed with fine, dispersed, and not numerous, straight, short *prickles*. *Leaflets* five, large, ovate, doubly serrated, overlapping each other at their heart-shaped base; the under side pale, downy or hairy, often whitish; the upper smooth, of a fine, rather shining, green. *Stipulas* linear-lanceolate, pointed, entire, downy and glandular. *Flowers* of a few large spreading *petals*, whose colour is a peculiarly rich and deep crimson, their base, like the *stamens*, of a fine golden yellow. Segments of the *calyx* downy, broad at the base, some of them fringed at the keel or margin, with a row of linear-lanceolate leaflets, as if pinnate. *Fruit* globular, pale scarlet, becoming nearly smooth as it ripens. The red and white parti-coloured variety, or *Rosa mundi*, Miss Lawrence's t. 13, differs only in colour. This is often termed the York and Lancaster Rose. The Giant Rose, her t. 49, is gigantic in size and height, but paler in colour. The Velvet Rose, her t. 51 and t. 2, Hort. Angl. t. 18, is of so very dark a colour, at least those flowers which first expand, that some persons take the liberty of calling it black, and confirm the misnomer by a round assertion of its being produced by grafting on a black-currant bush. The innumerable varieties of the *centifolia* differ chiefly in the disposition of their richly multiplied, though diminished, *petals*, and are, many of them, very beautiful from their fullness, and precise neatness of figure; their colours are different shades of crimson, verging to pink, or to a blueish-purple.

29. *R. damascena*. Damask Rose. Mill. Dict. ed. 8. n. 15. Willd. n. 17. Ait. n. 20. Lob. Ic. v. 2. 206. Lawr. Ros. t. 38. t. 52. t. 10. t. 5. t. 17. t. 70. t. 58. t. 18. t. 83. t. 80, and t. 90.—Fruit ovate, turgid, hispid as well as the flower-stalks. Stem and leaf-stalks with hooked prickles. Leaflets ovate, pointed, hoary; villous beneath. Calyx half-pinnate.—Native of the south of Europe, and cultivated, time out of mind, in our gardens, flowering in June and July. The specific name seems to have originated with Lobel, and indicates that this species of Rose came from Damascus. Perhaps it may be what is reported to have been brought from Syria by a Comte de Brie, at his return from the crusades, of which the abbé Rozier speaks in his Cours complet d'Agriculture; though that author's description accords with the common *R. gallica*, and not with our *damascena*, and he calls it moreover *R. provincialis*. We have seen an extract only from his work, communicated by a learned friend, to whom we, as well as Mr. Aiton, are indebted for the more correct orthography of Provins, instead of Provence, Rose, for our n. 26. We cite Rozier to shew that some particular sort of Rose was brought from Syria to France; but whether it might be our *damascena*, or the *moschata* hereafter mentioned, which many old authors have termed *damascena*, and which is certainly an oriental Rose; we have not materials

even to form a conjecture. The Damask Rose is proverbially sweet, nor can any be more so than the species now under our consideration, which forms a bush four or five feet high. The *leaves* are distinguished, at first sight, by a hoary aspect, and more downy surface, than the *provincialis* or *gallica*, as well as by the longer, more pointed, shape of their *leaflets*. The prickles of the *stem* are broader, and hooked. *Flowers* more copious, with more slender and hoary *stalks*, as well as *calyx*. Their usual colour is a delicate uniform pink, verging rather towards purple than scarlet, and their fragrance is deliciously sweet as well as lasting. The name of York and Lancaster Rose, given to a very casual and transient variety of this, Lawr. t. 10, some of whose petals are white, others blush-coloured, appears much more suitable to the red and white *R. gallica*.

30. *R. sempervirens*. Evergreen Rose. Linn. Sp. Pl. 704. Willd. n. 18. Ait. n. 21. Sm. Prodr. Fl. Græc. Sibth. v. 1. 348. Fl. Græc. t. 483, unpublished. Lawr. Ros. t. 45. Clus. Exot. append. alt. Dill. Elth. 326. t. 246. (*R. moschata sempervirens*; Tourn. Inst. 637.)—Fruit ovate, hispid as well as the calyx and flower-stalks. Stem and leaf-stalks with hooked prickles. Leaflets ovate, pointed, smooth and shining. Flowers somewhat umbellate. Bractæas lanceolate, recurved.—Native of Germany, in hedges near Tubingen. Roth. Dr. Sibthorp found it very frequent in the hedges of Greece, and the neighbouring islands, and judiciously considered it as the genuine *κνυοσβελιον* of Dioscorides, with whose rather ample description it exactly agrees. The reader may see in John Bauhin's Hist. v. 2. 33, what uncertainty has enveloped this subject. This Rose has been cultivated about two hundred years, or perhaps longer, in England, being, on account of its singularly luxuriant and rapid growth, as well as the beauty of its shining evergreen *leaves*, very fit for covering tall buildings, as well as for making an impervious hedge or trellis. The *flowers* moreover are beautiful, sweet, of a delicate white, and plentiful whenever they appear at all, lasting through June, July, and August; but we have, like Clusius, found this shrub little disposed to blossom. Its general aspect, both in *leaf* and *flower*, is most like our wild *R. arvensis*, n. 8; but the ovate *fruit*, yellow when ripe, and the want of a glaucous hue about the *foliage*, *flower-stalks* or *buds*, are, among other things, sufficient marks of difference.

31. *R. levigata*. Climbing American Rose. Mich. Boreal-Amer. v. 1. 295. Pursh n. 10.—“Fruit ovate, very densely hispid. Segments of the calyx nearly entire. Prickles in pairs, recurved. Leaf-stalks slightly prickly. Leaflets lanceolate-oval, almost ribbles, polished. Stipulas narrow, with awl-shaped points.”—Found in the shady woods of Georgia, North America, climbing to a great height. An evergreen *shrub*. *Leaflets* three or five. Tube of the *calyx* clothed with long and slender *spines*. Pursh, Michaux.

32. *R. pumila*. Dwarf Austrian Rose. Clus. Hist. 117. Linn. Suppl. 262. Willd. n. 19. Ait. n. 22. Jacq. Auflr. v. 2. 59. t. 198. (*R. austriaca*; Crantz Fasc. 2. 33.)—Fruit obovate, hispid as well as the flower-stalks. Leaf-stalks and stem with straightish prickles. Leaflets elliptical, glaucous beneath; their serratures glandular.—Common in Austria, on dry grassy hills, especially about woods and thickets, flowering in May and June. Jacquin. Root creeping. *Stems* twelve or eighteen inches high, erect, simple, or slightly branched, beset, in the upper part chiefly, with copious, small, slender, nearly straight *prickles*. *Leaflets* five, sometimes but three, drooping, of a roundish-elliptical shape, with double glandular serratures; smooth and green

green above; paler, glaucous, and sometimes downy, beneath. *Flowers* solitary, rather large, crimson; pale or whitish in the centre; very sweet-scented. Segments of the *calyx* partly pinnate, downy within and without. *Fruit* obovate, or pear-shaped, scarlet, more or less hispid, its pulp sweet and agreeable.—We are much inclined to refer this, as a variety, to *R. gallica*, n. 28; at least, if a more natural arrangement of the species were attempted, they ought to stand next to each other. Schleicher has found the *pumila* in Switzerland, nor can we doubt its being Haller's n. 1104, though Jacquin says the contrary, on the authority of a dried specimen, of what authority we know not. Haller, in his *Historia*, adopted his n. 1104 from other authors, nor did he there attempt a specific character; but in his *Nomenclator*, he has given one which precisely answers to Jacquin's plant.

33. *R. turbinata*. Frankfort Rose. Ait. ed. 1. n. 17. ed. 2. n. 23. Willd. n. 20. Lawr. Ros. t. 69, marked 63. (*R. campanulata*; Ehrh. Beitr. v. 6. 97. *R. inapertis floribus*, alabastro crassiore, francofurtensis quibusdam; Tourn. Inst. 639. *R. francofurtensis*; Park. Parad. 414. t. 415. f. 3.)—Fruit turbinate, hairy as well as the flower-stalks. Leaf-stalks and leaflets villous. Prickles scattered, hooked.—The native country of this Rose is not known; but the shrub has been cultivated in gardens, ever since the days of Parkinson, from June to August. There is an appearance of monotropy about the *calyx*, whose tube is bell-shaped, thick, and dilated at the top; the segments however are, most of them, quite simple and entire. *Petals* large, crimson. *Leaves* broad, villous.

34. *R. rubiginosa*. Common Sweet-briar, or Eglantine. Linn. Mant. 2. 564. Willd. n. 21. Ait. n. 24. Fl. Brit. n. 5. Engl. Bot. t. 991. Jacq. Austr. t. 50. Ehrh. Beitr. v. 4. 22. Arb. 75. Lawr. Ros. t. 56. t. 65. t. 72. t. 41. t. 61. t. 74. (*R. eglanteria*; Herm. Ros. 17. Hudf. Angl. 218. *R. suavisfolia*; Lightf. Scot. 262. Fl. Dan. t. 870. *R. sylvestris odora*; Ger. Em. 1269. f. 1. R. n. 1103; Hall. Hist. v. 2. 39.)—Fruit obovate, as well as the flower-stalks. Prickles of the stem and leaf-stalks hooked. Leaflets elliptical, clothed beneath with rusty-coloured glands.—Native of dry sunny banks in various parts of Europe, flowering in June and July; truly wild in many places in England, where the soil is gravelly or sandy, sometimes even in wet situations about rivers. The *stem* is bushy, much branched, about a yard high, with copious, broad, strongly hooked prickles, of a pale brown, all over its green branches. *Leaflets* five or seven, of a roundish, elliptical figure, with strong, double, glandular serratures; their upper surface bright green, slightly hairy; the under clothed with reddish viscid glands, the seat of a delightful fragrance, which renders the plant acceptable to most people, though often compared to the scent of apples, which many persons dislike. *Flowers* also sweet-scented, of a full and uniform pink; occasionally double, and sometimes pale or whitish, as represented in some of Miss Lawrence's plates. *Fruit* scarlet, more or less obovate, bristly, often nearly smooth; internally mealy and insipid. This well-known shrub makes beautiful and fragrant, though not long-lived, hedges. It bears forcing well, and hence is generally introduced, in winter or spring, into the apartments of those who delight in such innocent luxuries. Care should be taken to obtain the true sort, and not the following species.

35. *R. micrantha*. Small-flowered Sweet-briar. Sm. Engl. Bot. t. 2490.—Fruit ovate, somewhat bristly, as well as the flower-stalks. Stem straggling, with scattered hooked prickles. Leaflets ovate, acute, clothed beneath with rusty-coloured glands.—Mr. W. Borrer finds this

species of Rose common in hedges and thickets, in England, flowering about June and July. We have also met with it in gardens, confounded with the genuine Sweet-briar, from which it differs as follows. The *stem* is less prickly, less bushy, and of a more elevated and straggling form of growth, like *R. canina*. *Leaflets* less rounded, less rusty beneath, and not so fragrant as those of *rubiginosa*. *Flowers* paler, and smaller, being less than those of any other British Rose. *Fruit* ovate, with a more gradual neck, not obovate or pear-shaped. It varies in roughness. *Footstalks*, and backs of the *leaves*, downy as well as glandular.

36. *R. suaveolens*. American Sweet-briar. Pursh n. 11. ("R. eglanteria americana; Andrews's Roses, with a figure.")—Fruit ovate. Flower-stalks, and prickly leaf-stalks, rough with glandular bristles. Stem smooth; its prickles long, slender, slightly curved. Leaflets roundish-elliptical; downy above; somewhat glandular beneath.—Native of North America. We received specimens from Pennsylvania, gathered by the Rev. Dr. Muhlenberg. Linnæus cultivated this species at Upsal, and has preserved a branch, without name or description, in his herbarium. The plant differs from both the foregoing, in its long, slender, slightly curved, but by no means hooked, *prickles*, which often stand, two together, near, or close to, the base of the *leaf-stalks*. The *leaflets* are of a broad roundish form; finely hairy above; loosely besprinkled with stalked glands, though not rusty, beneath. *Flowers* pink, small, often, but not always, solitary, nor are the segments of the *calyx*, as Mr. Pursh describes them, always simple or entire; some of them are pinnate. *Fruit* smooth, or somewhat prickly.

37. *R. scabriuscula*. Roughish-leaved Dog Rose. Sm. Engl. Bot. t. 1896. (R. n. 459; Winch Guide, v. 1. 48. v. 2. preface, 5.)—Fruit roundish-ovate, bristly as well as the flower-stalks. Prickles awl-shaped, nearly straight. Leaflets elliptical, roughish with minute hairs.—Native of hedges in Durham and Northumberland, as well as on the north side of Bury in Suffolk, flowering in June.—This Rose has a general resemblance to *canina* and *tomentosa*, hereafter described; but its *pubescence* is hairy, more of the nature of the two or three last, as are also the glandular serratures of the *leaves*. There is a harshness about them, very unlike the *tomentosa*, nor have they any greyish hoary hue. Their scent is scarcely any. The *stem* is tall, with copious, scattered, nearly straight, and rather slender, brown *prickles*. *Leaf-stalks* hairy, prickly, and clothed with glandular bristles. *Leaflets* elliptical, pointed, doubly and sharply serrated, of a light bright green; finely hairy all over their upper surface, but moist so on the rib and veins beneath. *Flower-stalks* and young *fruit* beset with strong glandular bristles. *Calyx* partly pinnate; downy within; glandular and bristly at the outside. *Petals* moderately large; Mr. Winch finds them always white, tinged or blotched with red; in Suffolk they are mostly of a pale pink. *Fruit* large, red, inclining to a globular figure.

38. *R. cæsia*. Glaucous-leaved Dog Rose. Sm. Engl. Bot. t. 2367. (*R. canina pubescens*; Afzel. in Sims and Kon. Ann. of Bot. v. 2. 211.)—Fruit roundish-ovate, smooth. Prickles of the stem hooked. Leaflets ovate, pointed, doubly serrated, downy; very glaucous as well as the germen and young branches.—Found by Dr. Adam Afzelius in Sweden, and by Mr. W. Borrer in the highland valleys of Perthshire and Argyleshire, flowering profusely in July. Mr. Borrer describes the *bush* as "compact, not so tall as the *canina*. *Flowers* usually solitary; sometimes in pairs, generally of an uniform, but very beautiful, carnation hue; occasionally white. *Calyx* sometimes sprinkled with glands, sometimes not. Young *twigs*, *leaves* and *germen*

men remarkably caſious." His ſpecimens accord precifely with thoſe ſent by Dr. Afzelius. The very glaucous leaves, clothed on both ſides with fine hairy pubeſcence, eſſentially diſtinguiſhes this plant from *canina*, under which ſo many diſtinct ſpecies have been negligently confounded, by moſt botaniſts, till within a few years paſt. The fruit has been obſerved by Dr. Swartz to vary ſomewhat in form, being occaſionally oblong, obovate, or nearly globoſe: in a young ſtate it is glaucous and blueiſh; always ſmooth. *Calyx* partly pinnate.

39. *R. tomentofa*. Downy-leaved Dog Roſe. Fl. Brit. n. 4. Engl. Bot. t. 990. Ait. n. 31. (*R. villoſa*; Ehrh. Arb. 45. Villars Dauph. v. 3. 551. *R. fylveſtris* alba, cum aliquo rubore, folio hirsuto; Bauh. Hiſt. v. 2. 44.)—Fruit ovate, briftly as well as the flower-ſtalks. Prickles of the ſtem hooked. Leaflets ovate, downy on both ſides.—Native of woods, hedges, and thickets, in various parts of England, flowering in June and July. It is alſo found in Germany and Dauphiny. The ſtem is buſhy, and moderately tall. Prickles hooked, generally placed under the infertion of each leaf-ſtalk, either ſolitary or in pairs. Leaflets five or ſeven, ovate, acute, with fine double glandular ferratures, of a grey hoary green, denſely clothed on both ſides with ſoft pubeſcence, and, when rubbed, exhaling a ſlight aceſcent fragrance, moſt like the ſmell of *R. villoſa*, n. 20. *Calyx* pinnate, in the manner deſcribed in the generic character, clothed externally with glandular bristles. Fruit in every ſtate, more or leſs briftly, though ſometimes nearly ſmooth, while the flower-ſtalks are always very briftly; its colour when ripe is a tawny ſcarlet. Petals almoſt white towards their baſe, otherwiſe elegantly roſe-coloured, and a little fragrant. Specimens from Ehrhart and Villars have determined their ſynonyms; though the latter, at leaſt, by his deſcription, has apparently confounded the true *villoſa* with our *tomentofa*. So little were Roſes underſtood or conſidered at one time, that we recolleſt many grave debates among the Norwich botaniſts, about thirty years ago, whether this moſt diſtinct ſpecies were different or not from the common *canina*!

40. *R. canina*. Common Dog Roſe, Wild Briar, or Hep-tree. Linn. Sp. Pl. 704. Willd. n. 31. Ait. n. 30. Fl. Brit. n. 6. Engl. Bot. t. 992. Curt. Lond. faſc. 5. t. 34. Woodv. Med. Bot. t. 139. Fl. Dan. t. 555. Lawr. Roſ. t. 81. t. 60. Ehrh. Arb. 55. (*R. n. 1101*; Hall. Hiſt. v. 2. 38.)—Fruit ovate, ſmooth as well as the flower-ſtalks. Prickles of the ſtem ſcattered, hooked. Leaflets ovate, pointed, very ſmooth, unequally ferrated.—Very common in hedges and thickets in Britain, as well as throughout Europe, flowering in June. Few plants contribute ſo much to the ornament of the country, for it is certainly the moſt elegant of our Roſes; the ſcent of its flowers, and the flavour of its fruit, are both peculiarly grateful. The latter, when mellowed by froſt, affords a moſt agreeable conſerve, kept in the apothecaries' ſhops. The ſtem is often fix or ſeven feet high, erect and ſtraggling, with irregularly diſperſed, pale brown, broad prickles. Leaflets uſually ſeven, of a dark ſhining myrtle-like green; paler, or glaucous in ſome degree, underneath; with numerous, ſharp, unequal, not glandular, ferratures. Leaf-ſtalks ſmooth, armed with a few hooked prickles. Flower-ſtalks terminal, naked and very ſmooth, often ſolitary, ſometimes two, three, or four in a kind of umbel. *Calyx* downy, ſcarcely ever glandular. Fruit oblong-ovate, of a coral red, almoſt always quite ſmooth.

41. *R. collina*. Rough-ſtalked Dog Roſe. Jacq. Auſtr. v. 2. 58. t. 197. Willd. n. 32. Ait. n. 32. Engl. Bot. t. 1895.—Fruit ovate, ſmooth. Flower-ſtalks briftly, cluſ-

tered. Prickles of the ſtem ſcattered, hooked. Leaflets ovate, downy beneath, ſimply ferrated. Leaf-ſtalks downy.—Gathered by Jacquin on hills in Auſtria. Mr. W. Borrer finds it common in Suffex, flowering in July, and ripening fruit in October.—Its habit and general aſpect are like the *canina*. The prickles are diſperſed, hooked. Leaflets uſually ſeven, variable in length and roundneſs, ſimply, and tolerably equally, ferrated; always downy, or finely hairy, beneath, eſpecially the rib; ſometimes ſlightly ſo above. They have no ſcent, and are thicker, as well as leſs ſhining, than thoſe of *canina*. Leaf-ſtalks downy and prickly. Flowers pale pink, fragrant, commonly two or three together, on ſtalks covered with glandular bristles. Fruit in every ſtate ovate and ſmooth, except now and then a ſtraggling bristle or two; ſcarlet when ripe, and ſaid not to be diſtinguiſhable from *canina*. We have never taſted it. The ſtyles, after flowering, are combined and elongated, as in *R. arvenſis*.

42. *R. dumetorum*. Downy-ſtalked Dog Roſe. "Perf. Syn. part 2. ſect. 1. 50?" Engl. Bot. t. 2579.—Fruit ovate, ſmooth. Flower-ſtalks villous, ſomewhat briftly, cluſtered. Prickles of the ſtem hooked, rather aggregate. Leaflets ovate, doubly ferrated; ſlightly hairy beneath. Leaf-ſtalks very downy.—Gathered by Mr. W. Borrer, in buſhy places in Suffex, flowering in July, and ripening fruit in October. We believe it alſo to have been found in Switzerland, near Orbe, by the late Mr. Davall, and there is a ſpecimen, without name, or any mark, in the Linnæan herbarium. The ſynonym of Perfoon was ſuggeſted by Mr. Borrer, nor have we any further authority for its application. The habit of the ſhrub is more robuſt than *R. canina*, with very ſtrong hooked prickles, uſually placed in pairs under each footſtalk, and ſometimes three or more together under the lateral branches. It differs alſo from that ſpecies in having very downy footſtalks; leaflets rounder and flatter, doubly ferrated, their ribs and veins hairy beneath; the flower-ſtalks either villous and briftly, or only villous, with ſoft, ſpreading, permanent hairs; rarely ſmooth. Theſe hairs, and the double ferratures, diſtinguiſh it from *collina*, with which its downy leaf-ſtalks agree. The flowers are ſmaller and paler than in either of thoſe ſpecies. The ſtyles accord with *canina*, not with thoſe of *collina*.

43. *R. moschata*. Muſk, or Cluſter, Roſe. Mill. Diſt. ed. 8. n. 13. Willd. n. 23. Ait. n. 26. Deſfont. Atlant. v. 1. 400. Lawr. Roſ. t. 64. t. 53. Jacq. Hort. Schoenbr. v. 3. 16. t. 280. Ger. Em. 1265. f. 1 and 2. (*R. moſchata* minor, flore ſimplici; Bauh. Hiſt. v. 2. 45; and flore pleno; ibid. 47.)—Fruit ovate, villous when young, as well as the flower-ſtalks. Stem and leaf-ſtalks prickly. Leaflets oblong, pointed, ſmooth. Panicles many-flowered, downy as well as the calyx.—Deſfontaines found this elegant and fragrant Roſe growing every where in the hedges of Barbary. It is cultivated by the inhabitants of Tunis, who obtain from its petals, by diſtillation, a very fragrant eſſential oil; the ſame, if we miſtake not, which in the Eaſt Indies is called *Ottar*. The ſhrub is common in our gardens, and has been ſo from Gerarde's time, flowering from July to October. The ſemidouble kind moſt uſually occurs. The ſtems are long and lax, ſmooth, beſet with ſcattered, ſhort, hooked prickles. Leaves of a light, ſlightly glaucous green, eſpecially beneath, ſmooth, except ſome downineſs on their footſtalks, and their ribs beneath. Stipulas ſmall, narrow, fringed with glands, and divaricated at the points. Flowers rather ſmall, white, exceedingly numerous, in large terminal panicles, whoſe ſtalks are ſlender, downy, deſtitute of prickles or glands, as is likewiſe the ſlender, downy, partly pinnate, calyx. Petals with ſlender claws. Fruit ſmall, ſmooth, orange-coloured.—*R. moſchata* major, Bauh. Hiſt.

v. 2. 45. Lob. Ic. v. 2. 208, quoted by Miller incautiously for this, may be *R. damascena*.

44. *R. rubrifolia*. Red-leaved Rose. Villars Dauph. v. 3. 549. Willd. n. 24. Bellardi Append. ad Fl. Pedem. 23. t. 4. (Rosier multiflore; Reynier Mem. de la Suisse, v. 1. 222.—Fruit roundish-ovate, smooth as well as the flower-stalks. Prickles of the stem and leaf-stalks hooked. Leaflets ovate, smooth, coloured, simply ferrated. Flowers corymbose, with sheathing dilated bractæes and stipulas.—Native of the mountains of Switzerland, Dauphiny, and Savoy; a stranger to our gardens. The whole plant, branches, leaves, stalks, and tube of the calyx, are more or less tinged with a vinous red. The stem is erect and robust, ten to fifteen feet high, armed with scattered, distant, recurved prickles. Leaflets seven or nine, large, broadly ovate, with strong sharp serratures, smooth on both sides, with numerous, parallel, red veins. Stipulas red, smooth; the upper ones, near the flowers, much dilated, and replaced immediately by similar, but smaller, bractæes. Flowers from three to five, of a fine pink, forming a short smooth corymb. Segments of the calyx almost entirely simple, very long and slender, downy within, slightly glandular at the edges, each terminating in a long, lanceolate, leafy point. Fruit oval, small, smooth. Villars says the cultivated plant retains the peculiar red tints of its bark and foliage; only the size of the flowers is somewhat diminished.

45. *R. lagenaria*. Bottle-fruited Rose. Villars Dauph. v. 3. 553. Willd. n. 25.—Fruit obovate, beaked, smooth, pendulous. Stem without prickles. Leaf-stalks rather prickly. Flower-stalks downy, somewhat cymose. Leaflets elliptical, doubly ferrated, smooth as well as the calyx.—Native of France, in the district of Embrun, among the woods of Boscodon. Villars says he never met with this species elsewhere. He describes it as akin to the following, but differing in its large leafy calyx, and the greatly elongated spindle-shaped fruit, having a neck like that of a bottle. The stem is from three to five feet high, without thorns. Leaflets thin, obtuse. Flower-stalks three together, slightly downy, recurved. We have seen no specimen.

46. *R. alpina*. Alpine Rose. Linn. Sp. Pl. 703. Willd. n. 26. Ait. n. 27. Villars Dauph. v. 3. 552. Sm. Tour on the Cont. v. 3. 137. 140. Jacq. Austr. t. 279. Lawr. Ros. t. 30. (R. n. 1107; Hall. Hist. v. 2. 41.)—Fruit ovate, smooth. Stem without prickles. Leaf-stalks and flower-stalks bristly. Leaflets elliptic-oblong, doubly ferrated, smooth.—Very common in the alpine thickets of Switzerland, Savoy, Dauphiny, Austria, &c. flowering from June to August. It has long been cultivated in botanic gardens, but is not one of our popular species, being, though an elegant plant, and remarkable for the want of prickles, less striking than *R. pendulina*, which is also known by the name of "the Rose without a thorn." The present has smooth, spreading, sometimes procumbent, stems and branches, of a shining deep red, observed by Jacquin to be occasionally hairy or bristly, but never thorny. Leaflets seven or nine, elliptic-oblong, usually more than an inch in length, thin, smooth, doubly and sharply ferrated; paler beneath, with some hairs, now and then, on the midrib. Flowers generally solitary, of a rich and elegant rose-colour, on drooping, red stalks, clothed with glandular bristles. Calyx downy, with long, simple, slender, rather leafy-pointed segments; its tube generally smooth, though we have from M. Du Cros, a specimen with bristles on that part, as well as on the segments of the calyx. Fruit pendulous, oval, somewhat beaked, of a fine scarlet.—Miss Lawrence's t. 75 cannot possibly have any relationship to this species; see *lucida*, n. 14.

47. *R. pyrenaica*. Pyrenæan Rose. Gouan. Illustr. 31. t. 19. Willd. n. 27.

β. *R. pimpinellifolia*; Villars Dauph. v. 3. 553. (*R. glandulosa*; Bellardi Append. ad Fl. Pedem. 24.)

Fruit ovate, hispid as well as the flower-stalks, and somewhat prickly leaf-stalks. Stem without prickles. Leaflets elliptical, doubly ferrated, smooth.—Native of vallies among the Pyrenæan mountains, as well as of Switzerland and Dauphiny. We are fully persuaded that the *R. pimpinellifolia* of Villars is, as he himself suggests, but a variety of Gouan's *pyrenaica*, nor can we trace out sufficient marks to describe it even as a variety. The glandular edging of the stipulas, on which our worthy friend Bellardi has founded its character and name, is no less evident and constant in *pyrenaica*, and even in *alpina* itself; of which last indeed we are strongly inclined to consider the supposed species, both of Gouan and Villars, as mere varieties, differing from the usual kind in their bristly calyx and fruit. The segments of the calyx are simple, with more or less leafy points in all, nor does Gouan mention any thing that affords a permanent mark of discrimination between *pyrenaica* and *alpina*.

48. *R. pendulina*. Smooth Pendulous Rose. Rose without a thorn. Linn. Sp. Pl. 705. Willd. n. 28. Ait. n. 28. Pursh n. 12. Ehrh. Arb. 105. Lawr. Ros. t. 9. (*R. sanguiforbæ majoris folio, fructu longo pendulo*; Dill. Elth. 325. t. 245. f. 317.)—Fruit ovate, elongated, smooth, pendulous. Stem and branches smooth, without prickles. Flower-stalks and leaf-stalks hispid. Leaflets elliptical, doubly ferrated, smooth, rather numerous. Segments of the calyx simple, naked and entire. Dillenius says this species was raised, in the Eltham garden, from New England seeds; but Mr. Pursh never met with it wild in any part of North America; and Ehrhart gives his specimen as a Swiss plant. We believe however that it is a North American, not an European shrub. In our gardens it blossoms towards the end of May, ripening fruit in August. The stem is five or six feet high, bushy, smooth, dark red, nor is there a prickle to be found on any part of the plant. Leaves bearing a considerable resemblance to those of the Greater Burnet, *Sanguiforba*, and composed of from nine to thirteen large, elliptical, smooth leaflets, paler beneath, with double glandular serratures. Flowers solitary, crimson, on glandular, rather than bristly, stalks. Tube of the calyx oblong, very smooth; its segments quite simple, entire, narrow, downy at the edges, but destitute of dorsal prickles or glands. Fruit pendulous, scarlet, smooth and shining, remarkably elongated, beaked and curved, sufficiently discriminating the species, which nevertheless is nearly related to *R. alpina*, but in every part more robust.

49. *R. montana*. Round-leaved Mountain Rose. Villars Dauph. v. 3. 547. Willd. n. 29.—Fruit oval, bristly as well as the flower-stalks. Leaf-stalks prickly and glandular. Stem with hooked solitary prickles, below each leaf. Leaflets roundish, abrupt, doubly ferrated, smooth.—Native of hills in Dauphiny and Switzerland. A very distinct species, of which we have specimens from Mr. Schleicher. The stem is only two or three feet high, but strong, with many spreading, reddish, smooth branches. Prickles pale brown, moderately hooked or deflexed, awl-shaped, with a long linear base. They stand solitary, a little below each branch or leaf. Stipulas broad, fringed with glands. Leaf-stalks purplish, slightly prickly and glandular. Leaflets seven, somewhat glaucous, much resembling those of the Lesser Burnet, *Poterium*; their termination generally abrupt, and their serratures coarse, scarcely glandular; the midrib now and then hairy beneath. Flower-stalks terminal, short, very bristly and glandular, either solitary,

litary, or two or three together, enveloped in the uppermost stipulas. Petals small, generally white, sometimes red. Segments of the calyx, bristly and glandular at the back, partly pinnate. Fruit red, armed with many strong prickles. This species has but a remote affinity to either *canina* or *arvensis*, with which Villars contrasts it, except that the styles are said to be elongated, after flowering, as in the latter.

50. *R. multiflora*. Bramble-flowered Chinese Rose. Thunb. Jap. 214. Willd. n. 30. Ait. n. 29. Curt. Mag. t. 1059. ("R. flava; Donn. Cant. ed. 4. 121.")—Fruit ovate, villous, unarmed. Flower stalks villous, racemose. Stem and leaf-stalks prickly. Leaflets ovate, simply serrated; downy beneath.—Native of Japan and China. Introduced into this country by Thomas Evans, esq. of Stepney, about the year 1804. It is hardy, flowering in June and July, and a great acquisition to the gardens, being a shrub of luxuriant growth, easily trained to a considerable height. The leaves are of a greyish aspect; smooth above; paler and downy beneath; their serratures simple. Flowers in clusters, simple or compound, resembling those of the double-flowering Bramble, and not much larger. Thunberg describes them white; with us they are pink, with very numerous, small, imbricated petals, a few remains of stamens, and some elongated, dilated, greenish styles. The flowers, on the first introduction of the plant, were reported to be yellow, but we have not heard of any such variety having made its appearance.

51. *R. caucasica*. Caucasian Rose. "Marsch. Taurico-Caucas. v. 1. 400." Ait. n. 33.—"Fruit ovate, smooth as well as the flower-stalks. Leaf-stalks prickly. Stem not hairy; its prickles hooked. Leaflets doubly serrated, downy. Flowers umbellate."—Native of mount Caucasus, from whence it is said, in Hort. Kew., to have been brought to England about the year 1798. It is a hardy shrub, flowering in June and July. We have seen neither specimen nor figure. If the plant still exists in our collections, it ought to be delineated and given to the public.

52. *R. parvifolia*. Small-leaved, or Burgundy, Rose. Ehrh. Beitr. v. 6. 97. Willd. n. 33.—"Fruit ovate, nearly smooth. Flower-stalks glandular. Leaf-stalks and stem with minute straight prickles. Leaflets ovate, rugged; somewhat villous beneath; their serratures glandular." Said to be a native of Europe. A dwarf shrub. Leaflets five, small, ovate, acute. Flowers small. Willdenow. We know not what is intended under the above description; unless it be the Burgundy Rose, Miss Lawrence's t. 44, which we have, after the example of Hort. Kew. considered as a variety of *centifolia* or *gallica*, see n. 28. The characters answer, as far as any thing can be made out by the figure. We should have suspected the Rose de Meaux, Miss Lawrence's t. 31, might have been Ehrhart's and Willdenow's plant; but the latter has duly referred that, as we have done, to *provincialis* in its proper place, and having seen both in a living state, must be presumed to have distinguished them. There seems a great probability that the *parvifolia* in question is some garden variety of the *gallica*, to which its characters approach sufficiently near to authorize this opinion. We leave it for the final determination of those who may meet with authentic specimens.

53. *R. semperflorens*. Dark Chinese Rose. Curt. Mag. t. 284. Willd. n. 34. Ait. n. 34. Sm. Exot. Bot. v. 2. 63. t. 91. Lawr. Ros. t. 28. Jacq. Hort. Schoenbr. v. 3. 17. t. 281. (*R. diversifolia*; Venten. Jard. de Cels, t. 35.)—Fruit ovate, roughish. Stem, leaf-stalks, and flower-stalks, hispid or prickly. Prickles hooked. Leaflets three or five, ovate, smooth; paler beneath, with a hairy

rib. Calyx reflexed, entire.—Native of China, from whence it was introduced by the late Mr. Slater, about the year 1789. The shrub is perfectly uninjured by any of our frosts, and where the air is pure, grows luxuriantly in the open ground, flowering most part of the year. Yet it sometimes dies off unaccountably, and is not become so general an ornament of every cottage garden as the Pale Chinese-Rose, hereafter mentioned, brought to England about the same period. The *sempervirens* is generally of humbly growth, but in a rich loamy soil, on the outside of a greenhouse, may be trained to a considerable height. The stem is much and variously branched, armed with scattered, short, hooked prickles. Leaflets three or five, ovate, acute, rigid, unequally serrated; of a dark shining green, and smooth, above; paler, and rather glaucous, beneath, with a densely hairy rib. Leaf-stalks clothed with glandular bristles, and some soft hairs, as well as with a few hooked prickles. Stipulas linear, acute, fringed with stalked glands. Flower-stalks terminal, usually solitary, rough with glands or prickles, single-flowered. Segments of the calyx reflexed, lanceolate, coloured, simple and entire, downy, more or less fringed or glandular at the edges. Petals deep crimson, sometimes very dark, tremulous from the slenderness of their claws; paler at the back. The figures in Ventenat, and our Exotic Botany, exhibit the flowers in a single state; the rest have double flowers, as usually seen in gardens. Jacquin represents a supposed bluish-coloured variety, which is probably *indica*, n. 55. The fruit is mostly roughish, at least when young; but sometimes quite smooth. We have not met with it ripe. The shrub is readily increased by cuttings.

54. *R. chinensis*. Slender Chinese Rose. Jacq. Obs. fasc. 3. 7. t. 55.—"Fruit ovate, smooth as well as the flower-stalks. Leaf-stalks and stem prickly. Leaflets usually three, ovate-lanceolate, finely serrated, smooth."—Native of China. Described by Jacquin from some specimens belonging to Gronovius. He speaks of the leaves as perfectly smooth and shining, and the segments of the calyx fringed with down. The leaves were mostly ternate, some of them only having a small additional leaflet at one side. This is very likely to be, as Willdenow suspected, the same species with our *sempervirens*. If it should so prove, we hope the latter name, though of posterior date, will not be sacrificed to one so vague and indiscriminate as *chinensis*; especially as *sempervirens* is now established in systematic works of authority, and Jacquin himself, who, in his Hort. Schoenbr. considered these plants as the same, has liberally preferred it.

55. *R. indica*. Blush Chinese Rose. Linn. Sp. Pl. 705. Willd. n. 36. Ait. n. 35. (*R. semperflorens*  $\beta$ ; Lawr. Ros. t. 26. *R. longifolia*; Willd. n. 37.)—Fruit ovate, smooth. Flower-stalks bristly and glandular. Leaf-stalks glandular and prickly. Leaflets ovate, pointed, smooth; paler beneath. Prickles of the stem scattered, slightly hooked. Flowers somewhat corymbose. Calyx partly pinnate and leafy.—Native of China and the East Indies. Introduced by Sir J. Banks, about the year 1789, into the gardens of England, where it proves quite hardy, flowering profusely, almost throughout the year; and is undoubtedly one of the most desirable acquisitions, of the ornamental kind, that our collections have for a long time received. The shrub is of rapid and lofty growth, much stronger than *R. semperflorens*. Stem more or less armed with scattered, very strong, reddish, sharp, hooked or recurved prickles, which we have never found entirely wanting. Leaves of a full, bright, shining green on the upper side; paler, opaque, and a little glaucous, beneath; their leaflets for the more part five, ovate, taper-pointed, sharply and prettily

pretty equally, but not strongly, serrated. *Leaf-stalks* bordered with glandular bristles, and furnished with a few hooked prickles. *Stipulas* linear, narrow, reticulated, fringed with red glandular bristles; their points acute, divaricated at right angles. *Flower-stalks* terminal, very numerous and corymbose in strong-growing plants; in ordinary ones fewer; in some solitary and single-flowered at the ends of weak lateral branches. They are always clothed with minute glandular bristles, even in the original specimen of Linnæus, which he described as smooth. Neither are the *leaves* of that specimen downy beneath. He seems to have taken that character from another, which he confounded therewith, but which we judge to be *moschata*, whose very young *leaves* bear a few hairs on their ribs and veins. *Flowers* moderately large, in a double state consisting of numerous, lax, disorderly *petals*, varying with every tint of pink or carnation, and having a sweet, though light, odour, as in *semperflorens*, but not exactly the same. The perfume of both is very inferior to most of our garden Roses, and even to the wild *R. canina*. The *calyx* of *R. indica* is variable in luxuriance, but always in some degree leafy, pinnate, or jagged. *Fruit* large, pale scarlet. On a careful comparison of Willdenow's *longifolia*, (sent by the Rev. Dr. Rottler, and by the late Dr. Koenig, from the East Indies,) with our garden plant, and the Linnæan specimen, we can have no doubt of their perfect identity; though the prickles of the *stem* seem wanting on the upper part, at least, of the luxuriant Indian specimens. Every one, who has attended to the cultivated *R. indica*, will be aware that this circumstance is of no importance, in the consideration of such materials as we have before us.

56. *R. bracteata*. Macartney Rose, or Sir George Staunton's Rose. Willd. n. 38. Ait. n. 36. Venten. Jard. de Cels, t. 28. Curt. Mag. t. 1377. (*R. lucida*; Lawr. Ros. t. 84.)—*Fruit* obovate. *Braçteas* pectinated, concealing the flower-stalk, which is villous like the young branches. Prickles in pairs under the prickly leaf-stalks. *Leaflets* obovate, obtuse, crenate, smooth and shining. *Stipulas* deeply jagged. *Calyx* silky, taper-pointed.—Native of China, from whence it was brought by lord Macartney and sir G. Leonard Staunton, in 1795. It proves tolerably hardy in England, flowering from August to the end of autumn; but is often so much injured by exposure to our severe frosts, as seldom to recover sufficiently to blossom well in the ensuing summer. The *stem* is four or five feet high, downy, armed with a pair of deflexed reddish prickles under each *leaf-stalk*, and with innumerable minute straight ones over the whole surface. *Leaf-stalks* hairy, glandular, and prickly. *Leaflets* about seven or nine, rigid, shining, of a fine green; their ribs minutely prickly. *Stipulas* but little attached to the leaf-stalk, deeply cut, or pectinated, at one side. *Flowers* terminal, solitary, large, cream-coloured, agreeably scented, on short hairy stalks, which are concealed by several large, sheathing, deeply pectinate, or pinnatifid, *bracteas*. *Calyx* coriaceous, taper-pointed, very silky externally. Ventenat mentions a small central point, in the sinus of each *petal*, which we do not find constant. The *stipulas*, and especially the *bracteas*, are so peculiar, that this species can be confounded with no other.

57. *R. alba*. White Garden Rose. Linn. Sp. Pl. 705. Willd. n. 39. Ait. n. 37. Lawr. Ros. t. 37. t. 25. t. 23. t. 32. Ger. Em. 1260, with the same cut which Lobel uses for *R. damascena*.—*Fruit* ovate, smooth. *Flower-stalks* and *calyx* bristly. *Leaf-stalks* downy, armed like the stem with hooked prickles. *Leaflets* roundish-ovate, sharply serrated, downy beneath. *Calyx* partly pinnate.

—Native of Europe; in the hedges and thickets of Hesse and Saxony, according to Roth. Common in our gardens from the days of Gerard, flowering in June and July. The bush is five or six feet high. *Leaves* dark green, of five or seven large, broad *leaflets*, sharply and copiously serrated, veiny; paler, and more or less downy, beneath. *Stipulas* paler, broad, dilated upwards, with glandular serratures, and obliquely spreading points. *Flowers* large, somewhat corymbose, pleasantly but weakly scented, usually pure white, but often tinged with a most delicate blush, as in Miss Lawrance's t. 23 and t. 32. Segments of the *calyx* partly bordered with long leafy appendages, glandular at the edges. *Braçteas* like the *stipulas*, but more ovate. *Fruit* tawny, rarely perfected in gardens. We can give no good reason for placing the present species here, at a distance from *gallica*, n. 28, to which it is most naturally allied. No difficulty or confusion indeed can arise respecting a plant so well known, and so clearly defined. The White Rose was formerly an article of the *Materia Medica*, its distilled water, which possesses a slight astringency, being supposed good for inflammations and weaknesses of the eyes. A more fragrant water, equally colourless and efficacious, is distilled from the Provins rose, n. 26; which, we believe, is usually kept in the shops. In some of this, after long keeping, we have seen a floating oiliness, as deliciously and powerfully fragrant as the oriental otto of roses.

Our catalogue of species thus amounts to 18 more than Willdenow's, notwithstanding some retrenchments. The drawings of the Chinese afford reason to suppose we are not yet acquainted with all their species, and we have already hinted that some Irish ones are still waiting for more complete elucidation than they have hitherto received. The distribution of the species in general requires revision; nor have botanists sufficiently adverted to some characters, that appear to us more important than several they have depended upon. The number, and precise situation, of the sub-stipular prickles, the form of the stipulas, and the structure of the calyx, appear to us more constant, than the absence or presence of glands, or of pubescence, in certain parts. The nature of the serratures of the leaves, whether simple or double, glandular or not, is likewise occasionally worthy of notice.

ROSA, in *Gardening*, contains plants of the deciduous flowering, shrub, and evergreen kind, of which the species cultivated are: the single yellow rose (*R. lutea*); the double yellow rose (*R. sulphurea*); the Hudson's-bay rose (*R. blanda*); the cinnamon rose (*R. cinnamomea*); the white dog rose (*R. arvensis*); the small burnet-leaved rose (*R. pimpinellifolia*); the Scotch rose (*R. spinosissima*); the small-flowered American rose (*R. parviflora*); the shining-leaved American rose (*R. lucida*); the Carolina rose (*R. carolina*); the apple rose (*R. villosa*); the Provence rose (*R. provincialis*); the hundred-leaved rose (*R. centifolia*); the red rose (*R. gallica*); the damask rose (*R. damascena*); the evergreen rose (*R. sempervirens*); the dwarf Austrian rose (*R. pomila*); the Frankfort rose (*R. turbinata*); the sweet-briar rose (*R. rubiginosa*); the moss Provence rose (*R. muscosa*); the musk rose (*R. moschata*); the Alpine rose (*R. alpina*); the deep red China rose (*R. semperflorens*); and the white rose (*R. alba*).

Of the first there is a variety termed the Austrian rose, which has the stalks, branches, and leaves, like those of the single yellow rose, but the leaves are rounder. The flowers are also larger; the petals have deep indentures at their points; are of a pale yellow on the outside, and of a reddish copper colour, orange scarlet, or barré colour within; are single, have no scent, or a disagreeable one, and soon fall away.

away. It has sometimes flowers entirely yellow on one branch, and copper-coloured on another.

In the fourth species there is a double variety, in which the shoots are redder; the flowers small, short, thick, and double, of a pale red colour at the end of the leaves (petals), somewhat redder and brighter towards the middle. It is the smallest and earliest of the double garden roses, flowering in May.

In the seventh sort there are several varieties, as the striped-flowered, or with variegated flowers, red striped with white. The red Scotch rose, which seldom rises more than a foot high; the stalks are covered with a brown bark, and are closely armed with small spines; the leaves are very small; the flowers are also small, sessile, and of a livid red colour; the fruit is round, of a deep purple colour, inclining to black when ripe. And according to Withering, there is also a variety with prickly peduncles, and cream-coloured flowers, changing to white. Lawrance likewise mentions a double Scotch rose.

In the eighth kind there is a variety with a double flower.

Of the twelfth species there are several varieties, as the red Provence rose; the stem and branches are not so great as those of the other, but greener, the bark not being so red; the flowers are not so large, thick and double, but of a little deeper damask or blush colour, turning to red, but not coming near the full colour of the best red rose; nor is the scent so sweet as that of the damask Provence, but coming near that of the ordinary red rose. It is not so plentiful in bearing as the damask Provence. The blush Provence rose, in which the stalks rise from three to four feet high, and are unarmed; the leaves are hairy on their under side; the peduncles have some small spines; the segments of the calyx are semi-pinnate; the corolla has five or six rows of petals, which are large, and spread open; they are of a pale blush colour, and have a musky scent. The white Provence rose, which differs only in the colour of the flowers. The great and small dwarf Provence roses, called rose de Meaux, differ from each other in little except size; the smaller of the two is generally known by the nursery-men and gardeners by the name of Pomponne rose. It throws out numerous stems, which rarely exceed a foot, or a foot and half, in height; usually straight, rigid, and very prickly; the flowers very small, and distinguished by the brilliant colour of the central petals, appearing in June. All the sorts flower from July to August.

In the thirteenth species the varieties are very numerous; as the Dutch hundred-leaved rose; the blush hundred-leaved rose; the Singleton's hundred-leaved rose.

The single and double velvet rose, which, according to Parkinson, has the old stem covered with dark-coloured bark, but the young shoots of a sad green, with few or no thorns; the leaves are of a sadder green than in most roses, and very often seven on a stalk; the flower is single; or double, with two rows of petals, the outer larger, of a deep red, like crimson velvet; or more double, with sixteen petals or more in a flower, most of them equal: they have all less scent than the ordinary red rose. The Burgundy rose, which is an elegant little plant, not more than a foot or eighteen inches in height. The Sultan rose, the Stepney rose, the gurnet rose, the bishop rose, and the Lisbon rose.

In the fourteenth sort there are several varieties; as the red official rose, the Mundi rose, which has the flowers very elegantly striped or variegated with red and white: in other circumstances it so perfectly resembles the red rose, that there can be no doubt of its being a variety of that;

indeed it frequently happens that a red rose or two appears on the same plant with the variegated flowers. The Childing rose, the marbled rose, and the double virgin rose, which have great affinity with each other, according to Miller.

Of the fifteenth sort there are also several varieties, as the red damask rose, the blush damask rose, which differ only in the shade and colour. The York and Lancaster rose, which agrees with the damask in stalk, leaf, &c. differing only in the flower being variegated with white stripes. Mr. Hart's rose has the white stripes more distinct; the flowers in these being less double than in several others, are frequently succeeded by fruit, and have ripe seeds, from which other varieties may be obtained. According to Parkinson, sometimes one half of the petal is of a pale whitish colour, and the other half of a paler damask than common; or one petal is white or striped with white, and the other half blush or striped with blush; sometimes also striped or spotted over, and at other times little or no stripes or marks, and the longer it remains blown open in the sun, the paler and the fewer stripes, marks, or spots will be seen in it. The smell is of a sweet damask rose scent. The red monthly rose, the white monthly rose, which are so called from their continuing to blow in succession during the greater part of the summer; not that they blow in every month, as the name implies. They are, in every respect, like the damask rose, unless it be that they are more full of prickles than that. The blush Belgic rose, which rises about three feet high, with prickly stalks; the leaves are composed of five or seven leaflets, which are oval, hairy on their under side, and slightly serrate; the peduncles and calyxes are large and semi-pinnate; the flowers very double, of a pale flesh colour, with little scent, generally in great quantities. The red Belgic rose, which differs only in having the colour of the flower a deep red. The great royal rose, and the imperial blush damask rose.

In the nineteenth sort the cultivated plant grows larger and more erect; the leaves are bigger and much sweeter than in the wild one, the rusty colour of them disappears, and the whole puts on a more vigorous appearance; the sweet scent is supposed to proceed from the gland. There are varieties with double flowers; as the common double sweet-briar, the mossy double sweet-briar, the evergreen double sweet-briar, the red double sweet-briar, the royal sweet-briar, and the yellow sweet-briar.

Of the twenty-first kind there is a variety with double flowers. And the editor of Miller's dictionary considers the evergreen musk rose of Miller to be the same with this.

Of the twenty-fourth sort, according to Parkinson, there are two varieties of the white garden rose; one attaining sometimes the height of eight or ten feet, with a stock of a great bigness, the other seldom higher than a damask rose. Both have somewhat smaller and whiter-green leaves than in many other roses, five most usually on a stalk, and paler underneath; as also a whiter-green bark, armed with short prickles. The flowers in the one are whitish, with an eye of blush, especially towards the bottom, very double, and for the most part not opening so fully as the red or damask rose. In the other more white, less double, and opening more. Some have only two or three rows of petals; and all have little or no smell.

*Method of Culture.*—In all the sorts the increase may be effected by suckers, layers, or by budding upon stocks of other sorts of roses; but this last method is only practised for some peculiar sorts, which do not grow well upon their own stocks, and send forth suckers sparingly. Where more

## ROSA.

forts than one are to be had upon the same plant, such forts only should be budded upon the same stock as are nearly equal in their manner of growth, otherwise the stronger one will draw all the nourishment from the weaker.

The suckers should be taken off in October, and planted out either in nursery-rows, or in the places where they are to remain; as where they are permitted to stand upon the roots of the old plants more than one year, they grow woody, and do not form so good roots as if planted out the first year. The best method to obtain good-rooted plants is to lay down the young branches in autumn, which will take good root by the autumn following; especially when watered in dry weather; when they may be taken off from the old plants, and be planted out where they are to remain. The seeds are sometimes sown in the autumn, to produce new varieties, in beds of light mellow earth, or in drills, especially for the common sweet-briar kinds, and for raising hedges of them.

But although new varieties and some particular permanent forts, such as continue the same by seeds, may occasionally be raised in this way; all the double kinds and peculiar varieties, are by no means, in general, to be produced in this manner, as they cannot be continued, with certainty, the same by seeds, but constantly require, in this intention, to be raised from layers or suckers.

The most proper season for planting all the forts is the autumn or winter, when the weather is mild and open, when they will, for the most part, flower in full perfection during the succeeding summer, but, should there be a necessity, they may be replanted out even so late as the beginning of the spring months without much danger. And it is often an useful practice to set out a few plants in this late manner for the sake of a late long continued blow in the autumnal season. In general, however, the sooner the work of planting them out is performed, the stronger and more fully will the plants afford their flowers.

In planting them out in the common or shrubby borders, it should mostly be done in a single manner; and they may be trained with single stems to the height of one, two, or more feet, and then managed so as to branch out into bushy heads; and it is commonly adviseable to have them in this form; though some, for the sake of a more bushy growth, suffer them to branch away immediately from the bottom, as they will flower well in any mode of training.

Some, for curiosity, may also be run up with single stems to the height of from five or six to ten feet, and be kept in erect positions by means of proper supports, being made to form branchy heads at these heights, some running up more or less for the sake of greater variety. The large growing forts may likewise, in some cases, be planted out against walls, pales, &c. and be trained laterally as well as in an upright manner to some considerable extent.

Some plants of the early forts, as the monthly, &c. may also be set out in warm situations for more early blowing, and be treated in the same way.

But in the gardens about the metropolis, where large quantities of flowers of this kind are wanted for sale, the plants are generally set out in close rows, being put into the ground, in a fort of trench planting manner, at the distance of about a foot from each other, and afterwards kept down to the height of from not more than one to three feet, according to the forts and circumstances by cutting them over, or clipping them every autumn or winter, at the top and on the sides, by which lateral branches are sent off in greater abundance for future flowering.

All good gardens should mostly be possessed of the dif-

ferent sorts of these flowers, as they are easily procured, and multiply in an expeditious manner.

Some of the best forts of these plants may further also occasionally be put in pots for the purpose of being set out conveniently in different parts for the sake of ornament.

And where there are the conveniencies of hot-houses and forcing-frames, it may, in many cases, be desirable and proper to place some of the prime forts in pots for the purpose of being forced in such places for an early blow by means of artificial heat. In this way they may be made to flower either in the winter or early spring months. In which intention some potted plants of the monthly, common, or moss Provence, or other choice sorts of roses, must, in the winter, be set in the above sort of frame, wrought by dung, bark, or fire heat, or in a hot-house, which is by much the best, and be, by such means properly applied, forced into blow in the beginning of the new year and in succession for the two following months, and until the plants in the natural open ground begin to flower, different successional supplies of plants being so placed at the distance of every two or three weeks.

For this use a quantity of plants should, in general, be annually potted, which, if they have had a summer's growth in the pots, plunged in the ground, before they are employed in this way, it will be the better, as they will be more firmly rooted, and consequently blow in greater perfection and beauty. See *FORCING*, and *FORCING-FRAME*.

It is not unusual for the gardeners in the vicinity of the metropolis to form conveniencies of the above kinds in order to force flower-plants of this nature, as there is almost constantly a great demand and ready sale for them, at an early season, while they are in flower in the pots, as well as when the flowers are gathered in nosegays and other ways. They often pay extremely well in this manner of cultivating them.

Almost all the open ground forts delight in a rich moist soil and an open situation, in which they produce a greater quantity of flowers, and those much fairer, than when they are upon a dry soil, or in a shady situation. The pruning which they afterwards require, is only to cut out their dead wood, and take off all their suckers, which should be done every autumn; and if there are any very luxuriant branches, which draw the nourishment from the other parts of the plant, they should be taken out, or shortened, to cause them to produce more branches, if there be occasion for them to supply a vacancy; but it is best to avoid crowding them with branches, which is as injurious to these plants as to fruit-trees; for if the branches have not equal benefit from the sun and air, they will not produce their flowers so strong, or in so great plenty, as when they are more open, and better exposed to the sun, so as to have a more free circulation of air. As the moss Provence rose seldom sends out suckers, and does not strike very freely by layers, it is often increased by budding it upon stocks of the other forts; but the plants are best when raised from layers.

In general the best fort for flowering early and late is the monthly, next to which in flowering in the open air is the cinnamon, which is immediately followed by the damask rose, then the blush, York, and Lancaster; after which, the Provence, Dutch hundred-leaved, white, and most other forts; and the latest forts are the Virginian and musk roses, which, if planted in a shady situation, seldom flower until September, and if the autumn proves mild, continue often till the middle of October. And the plants of the two sorts of musk roses should be placed against a wall, pale, or other building, that their branches may be supported, otherwise they are so slender and weak as to trail upon

upon the ground. These plants should not be pruned until spring, because their branches are somewhat tender; so that when they are cut in winter, they often die after the knife; these produce their flowers at the extremity of the same year's shoots in large bunches, so that their branches must not be shortened in the summer, lest the flowers should be cut off. The shrubs will grow to be ten or twelve feet high, and must not be checked in their growth, if intended to flower well. They are all highly ornamental plants, mostly for the shrubby borders and clumps, being planted according to their habits of growth.

ROSA, SALVATOR, in *Biography*, so well known among the cognoscenti as the author of spirited and extravagant pictures of banditti, &c., was born at Naples in 1614, and received his first knowledge of design from his kinsman, F. Francazano; but by the death of his father, being reduced to extreme poverty, he was constrained to provide himself a maintenance by sketching designs upon paper, and selling them at any price he could obtain.

In that wretched situation he laboured for some time, till one of his designs, an historical subject of Hagar and Ishmael, accidentally happened to fall into the hands of Lanfranc. Pleased with the ability it displayed, he eagerly enquired for the artist; and as soon as he became acquainted with him, took him under his protection, and provided for him generously. This unexpected and happy change in his circumstances, enabled Salvator to pursue his studies with more effect; and he soon acquired considerable eminence, and his works were eagerly sought after.

The style which he formed is peculiarly his own, and his best productions are beautiful imitations of nature; but in general his works are artificial combinations, and wrought with extravagance; the spirit and fire with which they are executed, too frequently giving them a consequence and a name they do not deserve. This, indeed, may perhaps be said, that half the pictures which go under his name, are spurious or heavy imitations, and he pays the tax which all mannerists, like him, must submit to.

He certainly possessed a comprehensive genius; and was an excellent satirical poet, as well as an ingenious painter. In landscape painting he was entirely original, delighting in scenes of desolation and terror; these he peopled with banditti reposing, or lurking for their prey, or dividing their spoils; lonely shepherds, or forlorn travellers. Sometimes he attempted to create an interest by filling the scene he drew with some sacred or historic subject, but in this he seldom succeeded; his figures being ill proportioned, falsely attired, and void of expression. In colour he sometimes attained excellence. The dull, low, or lurid tone, which so justly becomes the character of loneliness, of forests almost impenetrable, or dreadful to see, and conveying ideas of danger in their aspect, he frequently presented most perfectly; and wrought the various parts with the greatest freedom of touch, and the utmost readiness of invention. His pictures are not unfrequent in our collections in this country; and genuine ones of the first quality are sold at extravagant prices. He died at the age of 59, in the year 1673.

Among musical MSS. purchased at Rome in 1770, was the music-book of Salvator Rosa, the painter, in which are contained, not only airs and cantatas set by Carissimi, Cesti, Luigi, Cavalli, Legrenzi, Capellini, Palqualini, and Bordini, of which the words of several are by Salvator Rosa; but eight entire cantatas written, set, and transcribed by this celebrated painter himself. The book was purchased of his great grand-daughter, who inhabited the house in which her ancestor lived and died. The hand-writing was

ascertained by collation with his letters and satires, of which the originals are still preserved by his descendants. The historians of Italian poetry, though they often mention Salvator as a satirist, seem never to have heard of his lyrical productions; and as this book is not only curious for the music it contains, but the poetry, we shall be somewhat minute in our account of its contents.

The first composition in this MS. was luckily a scene in Cesti's opera of *Orontea*, which it would have been difficult to have found elsewhere; for of the many hundred operas that were composed for the different theatres of Italy, during the last century, except two or three that have been printed, an entire copy, in score, it would be difficult to find, if not impossible.

II. Is a cantata by Capellini, a composer of no great eminence; yet there is in it a very pleasing air in triple time of  $\frac{3}{4}$ , in which the crotchets are expressed by minims hooked or tied like quavers.

III. Is an elegant simple air, by Legrenzi, sung to two different stanzas. See LEGRENZI.

IV. Is a beautiful Siciliana by Cavalli, the composer of *Erifina*. See CAVALLI.

V. Is a cantata written by Salvator Rosa, and set by Cesti. Recitative had not, as yet, banished formal closes, or regular modulation, which encroached too much upon air, and destroyed its narrative and declamatory plainness and simplicity.

Salvator was either the most miserable or the most discontented of men. Most of his cantatas are filled with the bitterest complaints, either against his mistress, or mankind in general. In this he says, that he has had more misfortunes than there are stars in the firmament, and that he has lived six lustres (thirty years) without the enjoyment of one happy day.

VI. Is a cantata set by Luigi, almost wholly in recitative, which, but for the formality of the closes, would be admirable. See LUIGI.

VII. Another cantata by the same composer, of which the words are very beautiful.

VIII. A cantata set by Carissimi, in which the melody is impassioned, and the recitative admirable. See CARISSIMI.

IX. Is a pleasing and natural air by Marc Antonio Pasqualini, which is repeated to different stanzas. The composer of this air was admitted into the Papal chapel in 1630; and from the year 1643 to 1670, he was a favourite stage-singer, with a soprano voice. Many of his compositions are preserved in the collections of the time, in which more grace and facility appear than force and learning.

X. A cantata, of which the words are by Salvator Rosa, and the music by Cesti. There are great strength and imagination in this poetry.

In the church of Santa Maria degli Angeli de' PP. Certosini, at Rome, where Salvator Rosa was buried, there is an inscription on his tomb, at which Crescimbeni, a Florentine, is angry; as it gives him *il primato sopra tutti i Rimatori Toscani*. This, like almost all monumental praise, is certainly hyperbolic; but Salvator's poetry seems to have great merit for its boldness and originality; it is indeed somewhat rough, even in his lyrics; and his satires are often coarse; but he appears to us always more pithy than his contemporaries, whom Marini's affectation had perhaps enervated and corrupted.

Salvator's cantata, of which we are now speaking, is the incantation of a female, distracted with love, disappointment, and revenge. This lyric poem seems to have furnished ideas to the author of Purcell's *Mad Bess*.—"By the

the croaking of the toad," &c. And in *Salvator* all the charms and spells of the witches in *Macbeth* are invoked.

XI. Is a gloomy, grumbling history of this painter and poet-musician's life, in which the comic exaggeration is not unpleasing; but it is rather a satire on the times in which he lived, than a lyric composition. However, it is set by *Bandini*; but being chiefly narrative, the music is almost wholly recitative; scarcely any measured melody being introduced, except to the first line, which serves as a refrain, or burden.

XII. Is an excellent cantata on the torments of *jealousy*, set by *Luigi*, in which there is more air and less recitative than usual at this period.

XIII. Is a single air by *Alessandro Scarlatti*, which must have been produced early in that great composer's life; as *Salvator*, in whose hand-writing it is entered in his book, died in 1675 (*Orlandi Abecario Pittorico*); some writers say in 1673. See *SCARLATTI*.

XIV. and XV. Are two single airs by *Legrenzi*, of which the melody is pleasing; they were perhaps sung in operas. The music of all the rest of the cantatas and songs in this book, amounting to eight, is of *Salvator's* own composition, and is not only admirable for a dilettante, but in point of melody superior to that of most of the matters of his time.

The two first are cantatas, but so ill written as to be difficult to read. The third begins with a pleasing air; and the fourth with such a spirited movement as the seventeenth century seldom produced. Two other airs in the same cantata are well accented, and pleasing. In the recitative of the fifth cantata, some of the first true closes occur that we have met with in narrative melody. There are several airs in this and the rest of *Salvator's* cantatas on pleasing subjects, and treated in a manner above mediocrity. The last of his airs is chiefly remarkable for its moving base: and if we only suppose this cantata to have been composed just before the author's death, it will be of a higher date than the publication, or perhaps the existence of any of *Corelli's* works, who is supposed to have been the inventor of this kind of pendulum base; which, however, frequently occurs in the cantatas of *Cesti*.

Whoever is curious to see specimens of *Salvator Rosa's* musical compositions, may find in the fourth volume of *Burney's Gen. Hist. Mus. fragments*, not only of his own productions, but of his contemporary composers of eminence, whose works he thought worth entering in his music-book. *Signorelli*, tom. v. p. 338.

ROSA DA TIVOLI. See *ROOS*.

ROSA, in *Geography*, a small island near the E. coast of *Sardinia*. N. lat.  $39^{\circ} 5'$ . E. long.  $9^{\circ} 3'$ .—Also, a town of *Germany*, in the county of *Henneberg*; five miles S. of *Saltzungen*.—Also, a town of *Spain*, in the province of *Seville*; eight miles S. of *San Lucar*.

ROSA. See *St. Rosa*.

ROSA, Cape, a cape on the coast of *Algiers*. N. lat.  $37^{\circ} 2'$ . E. long.  $8^{\circ} 5'$ .

ROSA, Mount, an eminence of the Alps, reckoned the second mountain of that famous ridge, lying about midway between *Great St. Bernard* and the lake of *Locarno*. *M. Saussure* visited this mountain, which has been reckoned only 60 feet inferior in height to *Mont Blanc*, this being estimated about 14,700 feet above the level of the sea. But in *George Shuckburgh's* table of heights taken by the barometer, &c. (*Phil. Trans.* vol. lxxvii. p. 592.) *Mont Blanc* is elevated 14,432 feet above the lake of *Geneva*, and 15,662 feet above the *Mediterranean*;

and *mount Rosa*, as measured geometrically by *Father Beccaria*, is 15,084 feet above the same sea.

ROSA Crucis, in *Church History*. See *ROSYCRUCIANS*.

ROSA Fatuina, in *Botany*, a name given by some authors to the piony.

ROSA Junonis, a name given by some authors to the lily.

ROSACEÆ, the 92d natural order in *Jussieu's* system, the 10th of his 14th class. See *FICOIDEÆ*, for the distinctions of that class. The characters of this large and important order, named from the Rose, and rose-like flowers, which compose it, are the following.

*Calyx* either superior, and tubular; or inferior, pitcher or wheel-shaped; its limb mostly divided, and generally permanent. *Petals* definite, usually five, inserted into the upper part of the calyx and alternate with its divisions; sometimes wanting. *Stamens* indefinite, rarely definite, inserted into the same part below the petals; others often roundish. *Germen* in some cases simple, inferior, the styles and stigmas mostly numerous; in others superior, simple, with one style, or manifold with many styles; the styles in every instance lateral, or proceeding from the side of each germen. Structure of the fruit various; in some an inferior apple, of many cells, or a sort of cup or urn, apparently inferior, bearing many seeds, over which it closes; in others the seeds, or seed-vessels, each of one cell, and mostly single-seeded, indefinite or definite, are superior, standing on a common receptacle; in others, again, there is either a solitary superior capsule of one cell; or a superior nut, with one or two seeds, which is either naked, or invested with a drupaceous coat. The scar of each seed is lateral, just below the summit, connected by a thread, or umbilical cord, with the lower part of the seed-vessel. *Corkulum* straight, without an *albumen*. *Stem* herbaceous, shrubby, or arboreous. *Leaves* either simple or compound, alternate, accompanied by *stipulas*.

Section 1. POMACEÆ. *Germen* simple, inferior, with many styles. *Apple* umbilicated, or bordered, with the limb of the calyx, of many cells. Trees or shrubs.—This section contains the Linnæan genera of *Pyrus*, (from which *Jussieu* distinguishes *Malus* and *Cydonia*), *Mespilus*, *Cratægus*, and *Sorbus*.

Section 2. ROSÆ properly so called. *Germens* several, indefinite, invested with the urn-like calyx contracted at the top, so that they seem inferior; each accompanied by one style. Seeds as many. Shrubs.—*Rosa* here stands alone.

Section 3. SANGUISORBÆ. *Germens* several, definite, rarely solitary, invested with cup-like calyx contracted at the top, so that they seem inferior; each with one style. Seeds as many. Mostly herbaceous, many of them without petals, many with a definite number of stamens, some with stamens and pistils in separate flowers.

*Poterium*, *Sanguisorba*, *Ancistrum*, *Acana*, *Agrimonia*, *Neurada*, *Cliffortia*, *Aphanes*, *Alchimilla*, and *Sibbaldia*.

Section 4. POTENTILLÆ. *Germens* several, indefinite, truly superior, standing on a common receptacle, each with one style. Seeds as many, naked, rarely pulpy.—Herbs, rarely shrubs.

*Tormentilla*, *Potentilla*, *Fragaria*, *Comarum*, *Geum*, *Dryas*, *Rubus*; to which is to be added our *Duchefnea*, (see *FRAGARIA*, at the conclusion) now described in *Tr. of Linn. Soc.* v. 10. 372.

Section 5. SPIRÆÆ. *Germens* several, definite, superior, each with one style. Capsules as many, with one or more seeds.—Shrubs, rarely herbs.

*Spiræa*, *Suriana*, and *Tetracera*.

Section 6. PROCKIÆ. *Germen* single, superior, with one style.

*Style.* Fruit of one cell, with one or more seeds.—Trees or shrubs, sometimes destitute of petals.

*Tigarea* of Aublet; *Delima*, *Prockia*, and *Hirtella* of Linnæus.

SECT. 7. AMYGDALÆÆ. *Germen* single, superior, with one style. Nut either naked, or more usually invested with a pulpy coat, and containing one or two seeds.

*Hedycera* of Schreber, which is Aublet's *Licania*; *Grangeria* of Commerfon; *Chryfobalanus* of Linnæus; *Cerafus*, *Prunus* and *Armeniaca* of Tournefort, all three included in the Linnæan *Prunus*; *Amygdalus* of Tournefort and Linnæus, including *Persica* of the former; *Moquilea*, *Couepia*, and *Acia* of Aublet, (the latter Schreber's *Acia*); and *Parinari* of Aublet, which is Schreber's *Petrocarya*.

SECT. 8. *Genera akin to the Rosacea.*

*Plinia* of Plumier and Linnæus, the uncertainty of whose history we have fully explained; see *PLINIA*.

*Calycanthus*, allied by its fruit to *Rosa*, but the leaves are opposite and simple, and the flower in a manner apetalous.

*Ludia* of Commerfon; *Black-wellia* of the same author; *Homalium* of Jacquin and Linnæus; and *Napimoga* of Aublet. The three last appear to constitute one genus; see *HOMALIUM*.

ROSACEOUS COROLLA, is one which consists of several petals ranged in a circle; so that, according to Tournefort's acceptation of the word, it includes, not only the natural order of ROSACEÆ, (see that article,) and other flowers agreeing therewith in having mostly five petals, as *Ranunculus*; but even such as have only two, like *Circæa*. The author is obliged to exclude the Cruciform and Umbelliferous plants from this order by a particular and arbitrary exception; for according to his primary idea, it would admit every polypetalous regular flower, as well as some that are irregular, as *Cassia*, &c. See *COROLLA*.

ROSACLORUM, or, according to some authors, *Rosichiero*, a fine red used to enamel on gold with. It is prepared in this manner: take ten pounds of crystal-glass, put it into a pot, and when it is well melted, add to it, at twice, a pound of the best red-lead; stir the mass well together, and afterwards cast it into water. Repeat this process three times, then when the matter is again in fusion, mix with it five ounces of calcined brass, and the same quantity of the deepest cinnabar; stir the whole well together, and let it settle three hours; then add of glass of tin three ounces, mix the whole, and it will be of a fine rose-colour. Merret's Notes on Neri, p. 350.

ROSADE, a kind of liquor, prepared of pounded almonds and milk, mixed with clarified sugar.

ROSALBA, *CARRIERA*, in *Biography*, was of Chiozza, and carried crayon painting to a high degree of perfection. Orlandi celebrates her miniatures. Her crayon painting arrives, not seldom, at the strength of painting in oil. Her portraits spread all over Europe, are as elegant and graceful in conception and attitude, as fresh, neat, and alluring in colour. Her Madonnas, and other sacred subjects, rise from grace to dignity, and even majesty. Equal and incessant application deprived her of sight during the last ten years of her life. She died in 1757, at the age of 82.

Rosalba is celebrated by Walther for her musical talents and exquisite taste in singing.

ROSALE, in *Geography*, a town of Persia, in the province of Fars, or Farsistan; 15 miles W. of Kazerou.

ROSALGATE, CAPE. See *RASALGATA*.

ROSALIA, a name used by authors for the measles, or

a disease very like the measles, consisting of a number of apertures and protuberances of the skin, which soon die away.

ROSALIA, in *Music*. See *REPETITIONS*.

ROSALIND, a mask, written by Lockman, set by Smith for Hickford's rooms, and performed there in still life, oratorio wise, in 1740. This little drama would not be mentioned here, as the poetry is upon a level with Mr. Lockman's other productions; and of the music we know nothing, as it was never published. But as, "to raise the pamphlet price a shilling," the poetry is preceded by "inquiries into the origin of operas."

ROSAMARINA, in *Geography*, a town of Sicily, in the valley of Demona, at the mouth of a river of the same name, which runs into the sea, 10 miles N.E. of Millretta.

ROSAMOND, in *Biography*, daughter of lord Clifford, was a young lady of great beauty, fine accomplishments, and endowed with the most engaging wit and sweetness of temper. She had been educated, according to the custom of the times, in the nunnery of Godstow, and the popular history of her is as follows. Henry II. of England saw her, was smitten with her beauty, and triumphed over her honour. To avoid the jealousy of his queen, Eleanor, he kept her in a labyrinth at Woodstock, and by his connection with her had two children, who were afterwards William Longsword, earl of Salisbury, and Geoffrey, bishop of Lincoln. On Henry's absence in France, the queen found means to discover her, and, jealous of her great beauty, caused her to be poisoned. This story is not well supported by historical documents. Several writers mention no more of her, than that the queen caused her to be so harassed, that she did not long survive after she was discovered. Other writers assert, that she died a natural death, and the story of her being poisoned is supposed to have arisen from the figure of a cup being placed on her tomb. She was buried in the church of Godstow, opposite to the high altar, where her body remained till it was ordered to be removed with every mark of disgrace by Hugh, bishop of Lincoln, in 1191. By many, however, she has been regarded as a saint, but her history is in every respect very uncertain. See *Grofe's Antiq. of Eng. and Wales*.

ROSAMOND, an English opera, written by Addison on the Italian model. After the great success of *Artinoe* and *Camilla* in 1705 and 1706, in which the dialogue was wholly spoken in recitative, and the performers all English fingers; in 1707, notwithstanding the deficiencies of those dramas in poetry, music, and performance (for as yet no foreign composer or captivating singer was arrived) this kind of exhibition became so formidable to our own actors, that a subscription was opened the beginning of this year, "for the encouragement of the comedians acting in the Haymarket, and to enable them to keep the diversion of plays under a separate interest from operas." *Daily Courant*, January 14th, Cibber gives a circumstantial account of this humiliating transaction, and speaks of its success with considerable triumph. See *CLAYTON*.

The verses of Rosamond are highly polished, and more lyrical perhaps than in any poem of the same kind in our language. And yet this drama is not wholly free from opera absurdities, on which Addison was afterwards so severely pleasured. For instance, the king's approach to the secret bower of bliss, where his fair Rosamond was treasured up from the resentment of his jealous queen, is always announced and published by a loud concert of military instruments: *Act i. sc. 1.*

"Hark,

“ Hark, hark ! what found invades my ear ?  
The conqueror’s approach I hear.  
He comes, victorious Henry comes !  
Hautbois, trumpets, fifes, and drums,  
In dreadful concert join’d,  
Send from afar the found of war,  
And fill with horror ev’ry wind.”

It was the fashion in almost all the serious operas that were written in Italy, before the time of Apostolo Zeno and Metastasio, to mix comic and buffoon characters with the tragic, even in *dramme sacri*, notwithstanding the severity of some Italian critics upon our Shakspeare for the same practice.

And Mr. Addison has fully complied with this custom, in the characters of Sir Truitt and Grideline, which are of the lowest species of comic.

If it can be proved that gunpowder was invented, and in military use in the time of Henry II. Mr. Addison was guilty of an anachronism in making him alk,

“ Why did I not in battle fall  
Cruel’d by the thunder of the Gaul ?”

The loss of Rosamond in the second act of this drama is not compensated by a single interesting event in the third, which drags and languishes for want of her so much, that neither the flat and forced humour of Sir Truitt and Grideline, nor the elegant compliments made to the duke of Marlborough and Blenheim, ever kept the audience awake in the performance.

In 1733, Rosamond was set by Mr. (afterwards Dr.) Arne, his first attempt at dramatic music, in the performance of which his sister, Miss Arne, afterwards the justly celebrated actress Mrs. Cibber, performed the part of Rosamond. The airs in this *coup d’essai* of Arne, were extremely pleasing, and far superior to those of any English composer of that period. Many of them were afterwards sung at Vauxhall by Mrs. Arne and Low with great applause. “ Was ever Nymph like Rosamond,” was long in universal favour all over the kingdom.

ROSAN, in *Geography*, a town of the duchy of Warfaw, on the Narew; 110 miles E. of Thorn.

ROSANA, a river of Germany, which runs into the Inn, near Landeck, in the county of Tyrol.

ROSANI, CAPE, a cape on the coast of Romania, in the Grecian Archipelago. N. lat. 40° 35'. E. long. 24° 14'.

ROSANNA, a town of Lithuania, in the palatinate of Novogrodek; 36 miles W. of Novogrodek.

ROSARBA, in *Botany*, the name of an imaginary plant, which has given great trouble to the commentators on the works of the ancients.

The Arabian writers, Avicenna, Serapion, and others, have mentioned two kinds of carob or ceration; the one esculent, and endowed with the virtue of a gentle purgative, the other an astringent.

This last they have distinguished from the other by the name of the nabathean pod or aljembut. They say in their descriptions, that the aljembut is like the rosarba; so run the old translations, but the true meaning of the original is *rosa vinea*. This was a name given to the common wild acacia-tree, and the tree which produced the nabathean pod, might be very well likened to this; it being, in reality, only a species of the acacia, and the fuccus acacie, or inspissated acacia juice of the shops, being, according to Isidore, made oftentimes from the unripe fruit of this very species.

ROSARIA, among the Romans, a kind of perfumes, so called either from their being chiefly made of roses, or because they had a most exquisite odour.

ROSARIO, in *Geography*, a small island in the Spanish main, near the coast of Carthagea. N. lat. 10° 5'. W. long. 75° 56'.—Also, a town of New Navarre; 30 miles S.W. of Casa Grande.—Also, a town of South America, in the province of Tucuman; 78 miles N. of St. Miguel de Tucuman.—Also, a town of Brazil, in the government of Minas Geraes; 220 miles N. of Villa Rica.—Also, a town of North America, in the county of California; 30 miles S.W. of Loreto.—Also, a town of the island of Cuba; 45 miles S. of Havannah.

ROSARIO, El, a town of Mexico, in the province of Chiapa; 140 miles S.E. of Chiapa dos Espagnols.

ROSARIO, or *Neustra Señora del Rosario*, a canal of a strait in the gulf of Georgia, which separates the island of Florida from America; about 30 miles in length. At the S.E. extremity the canal is six miles broad; but towards the N.W. its breadth is gradually diminished to two miles, in its narrowest part.

ROSARUM ACETUM. See ACETUM.

ROSARUOLO, in *Geography*, a town of Istria; 8 miles E. of Capo d’Istria.

ROSARY, in the *Romish Church*, a chaplet consisting of five or fifteen decads of beads, to direct the recitation of so many Ave Maria’s, in honour of the Virgin.

ROSARY also denotes a particular mass or form of devotion addressed to the Virgin, to which the chaplet of that name is accommodated. It consists of fifteen repetitions of the Lord’s prayer, and an hundred and fifty salutations of the blessed Virgin; whilst the *crown*, as it is called, according to the different opinions of the learned concerning the age of the Virgin, consists of six or seven repetitions of the Lord’s prayer, and six or seven times ten salutations or Ave Maria’s.

Some attribute the institution of the rosary to St. Dominic; but F. d’Achery shews it was in use the year 1100; so that St. Dominic could only make it more celebrated. Others attribute it to Paulus Libycus, and others to St. Benedict; others to the Chartreux; others to Venerable Bede; and, finally, others to Peter the Hermit. Those who ascribe it to St. Dominic, differ as to the particular time of its institution; some referring it to the year 1208, when he preached against the Albigenes; others will have him to have set it on foot in the course of his missions in Spain, before he passed into France.

ROSARY, *Order of the*, or of *our Lady of the Rosary*, is an order of knights, supposed by Schoonebeck, and the Jesuit Bonanni, to have been instituted by St. Dominic, but by mistake; for that saint never instituted any order under this name, and these authors apparently make a military order of an army of crosses, who, under the command of the count de Montfort, fought against the Albigenes.

The abbot Justiniani, and M. Hermant, will have this order to have been established by an archbishop of Toledo, named Frederic, after St. Dominic’s death; and to have borne for a badge a black and white cross, in the middle of which was represented our Lady, holding her little son in one hand, and in the other a rosary. F. Mendo adds, that they were obliged to rehearse the rosary on certain days. After all, F. Helyot doubts whether or no such an order in reality ever existed. Edmondson refers the institution of this order to the year 1212; and he says, the badge of the order was a cross patonce per cross countercharged argent and sable, surmounted on the centre with a medal or, enamelled

melled with the image of the Virgin, supporting the infant in one hand, and holding a rosary in the other, all proper. The order of the "Celestial Collar of the Holy Rosary" is a religious order for ladies, instituted at the request of father Francis Arnoul, a Dominican, by queen Anne of Austria, widow of the French king Lewis XIII., and mother of Lewis XIV., for fifty young ladies of the first families in France. The collar of the order was composed of a blue ribbon, enriched with white, red, and maiden's blush roses, interlaced with the capital letters A. V. in cypher affixed to it; and pendent at the breast by a silk cordon, a cross of eight points pomettée, and in each angle a fleur-de-lis: on the centre the image of the Virgin Mary, and on the reverse the image of St. Dominic, enamelled.

ROSARY is a word frequently met with in the ancient histories of Ireland, and used to express a peculiar sort of base money coined abroad, in the form of the penny, current in that kingdom; but of so much baser an alloy, that it was not worth quite half the real value of the penny. This and many other such coins were decried, and it was made death to import any of them, by Edward I., in 1300.

ROSARY, *Persian*, a beautiful compendium of oriental ethics, written by a Persian poet, whose name was Eddin Sadi; who, about the middle of the 13th century, when the Turks invaded Persia, withdrew from his own country, and settled at Bagdad, for the purpose of prosecuting his studies. After experiencing much vicissitude of fortune, he returned home, and compiled the book just mentioned, which he completed in the year 1257. This book, we are informed, has been universally read in the East; and has been translated into Latin, and into several modern languages. As our readers in general may not have access to the original work, which is divided into eight chapters, nor to extracts from it, we shall here subjoin, both for their information and amusement, the following citations.

1. Paradise will be the reward of those kings who restrain their resentment, and know how to forgive. A king, who institutes unjust laws, undermines the foundation of his kingdom. Let him, who neglects to raise the fallen, tear, lest when he himself falls, no one will stretch out his hand to lift him up. Administer justice to your people, for a day of judgment is at hand. The dishonest steward's hand will shake, when he comes to render an account of his trust. Be just, and fear not. Oppress not thy subjects, lest the sighing of the oppressed should ascend to heaven. If you wish to be great, be liberal; for, unless you sow the seed, there can be no increase. Assist and relieve the wretched, for misfortunes may happen to yourself. Wound no man unnecessarily; there are thorns enough in the path of human life. If a king take an apple from the garden of a subject, his servants will soon cut down the tree. The flock is not made for the shepherd, but the shepherd for the flock.

2. Excel in good works, and wear what you please: innocence and piety do not consist in wearing an old or coarse garment. Learn virtue from the vicious; and what offends you in their conduct, avoid in your own. If you have received an injury, bear it patiently: by pardoning the offences of others, you will wash away your own. Him, who has been every day conferring upon you new favours, pardon, if, in the space of a long life, he should have once done you an injury. Respect the memory of the good, that your good name may live for ever.

3. In your adversity, do not visit your friend with a sad countenance; for you will embitter his cup: relate even your misfortunes with a smile; for wretchedness will never reach the heart of a cheerful man. He who lives upon the

fruits of his own labour, escapes the contempt of haughty benefactors. Always encounter petulance with gentleness, and perverseness with kindness: a gentle hand will lead the elephant itself by a hair. When once you have offended a man, do not presume that a hundred benefits will secure you from revenge: an arrow may be drawn out of a wound, but an injury is never forgotten. Worse than the venom of a serpent is the tongue of an enemy, who pretends to be your friend.

4. It is better to be silent upon points we understand, than to be put to shame by being questioned upon things of which we are ignorant. A wife man will not contend with a fool. It is a certain mark of folly, as well as rudeness, to speak whilst another is speaking. If you are wise, you will speak less than you know.

5. Although you can repeat every word of the Koran, if you suffer yourself to be enslaved by love, you have not yet learned your alphabet. The immature grape is sour; wait a few days, and it will become sweet. If you resist temptation, do not assure yourself that you shall escape slander. The reputation, which has been fifty years in building, may be thrown down by one blast of calumny. Listen not to the tale of friendship, from the man who has been capable of forgetting his friend in adversity.

6. Perseverance accomplishes more than precipitation; the patient mule, which travels slowly night and day, will in the end go further than an Arabian courser. If you are old, leave sports and jests to the young: the stream, which has passed away, will not return into its channel.

7. Instruction is only profitable to those who are capable of receiving it: bring an ass to Mecca, and it will still return an ass. If you would be your father's heir, learn his wisdom: his wealth you may expend in ten days. He who is tinctured with good principles while he is young, when he is grown old will not be destitute of virtue. If a man be destitute of knowledge, prudence, and virtue, his door-keeper may say, Nobody is at home. Give advice where you ought; if it be not regarded, the fault is not yours.

8. Two kinds of men labour in vain: they who get riches, and do not enjoy them; and they who learn wisdom, and do not apply it to the conduct of life. A wise man, who is not at the same time virtuous, is a blind man carrying a lamp: he gives light to others, whilst he himself remains in darkness. If you wish to sleep soundly, provide for to-morrow. Trust no man, even your best friend, with a secret; you will never find a more faithful guardian of the trust than yourself. Let your misfortunes teach you compassion: he knows the condition of the wretched, who has himself been wretched. Excessive vehemence creates enmity; excessive gentleness, contempt: be neither so severe, as to be hated; nor so mild, as to be insulted. He who throws away advice upon a conceited man, himself wants an adviser. In a single hour you may discover, whether a man has good sense; but it will require many years to discover whether he has good temper. Three things are unattainable; riches without trouble, science without controversy, and government without punishment. Clemency to the wicked is an injury to the good. If learning were banished from the earth, there would, notwithstanding, be no one who would think himself ignorant. Brucker's Hist. of Philos. by Enfield, vol. ii.

ROSAS, in *Geography*, a sea-port town of Spain, in Catalonia, on the north side of a gulf of the Mediterranean, to which it gives name, with a good harbour, defended by a fort. It was anciently called "Rhoda," and "Rhodope;" 22 miles N.E. of Gerona. N. lat. 42° 17'. E. long. 3° 0'.

ROSATA ALOE. See ALOE.

ROSATE, in *Geography*, a town of Italy, in the department of the Olona; 9 miles S.W. of Milan.

ROSATUM ACETUM. See ACETUM.

ROSATUM Vinum. See VINUM.

ROSAZZO, in *Geography*, a town of Italy, in Friuli; 6 miles S. of Friuli.

ROSBACH, a town of Germany, in the county of Sayn; 8 miles E. of Hachenburg. See ROSSBACH.

ROSBEGH POINT, a cape on the west coast of Ireland. N. lat.  $52^{\circ} 6'$ . W. long.  $9^{\circ} 52'$ .

ROSBOTH, a word used by some authors to express a soft excrescence from any part.

ROSCHINTZE, in *Geography*, a town of Prussia, in Natangen; 12 miles S. of Lick.

ROSCHITZ, a town of Austria; 2 miles S.W. of Schtrattentaal.—Also, a town of Moravia, in the circle of Brunn; 8 miles W. of Brunn.

ROSCIUS, QUINTUS, in *Biography*, a Roman actor of great celebrity, was a native of Gaul. He was contemporary at Rome with the celebrated actor Esopus. So great were his talents for the stage, and such was the degree of perfection to which he carried his art, that, according to Cicero, a complete master in any other art was popularly called the Roscius of it. Roscius was not less esteemed for his morals and good conduct, than admired for his professional talents. The greatest men in the state were his intimate friends, and the loss of him was universally lamented. "Which of us," says Cicero, alluding to Roscius in his oration for the poet Archias, "was so rude and unfeeling as not to be affected by the recent death of Roscius, who, though he died at an advanced age, appeared, on account of his excellence in his art, worthy of immortal life." His death took place in the year 61 B.C. He composed a parallel between theatrical and oratorical action, which is lost.

There are several passages in Cicero concerning Roscius, which, if the ancient actors, Romans as well as Greeks, did not declaim in musical notes, would be wholly unintelligible. He tells us (de Orat.), that Roscius had always said, when age should diminish his force, he would not abandon the stage, but would proportion his performance to his powers, and make music conform to the weakness of his voice; which really happened: for the same author informs us (de Leg.), that in his old age he sung in a lower pitch of voice, and made the tibicines play slower.

As there were combats, or contests, established by the ancients for the voice, as well as for other parts of the *Gymnastice*, those who taught the management of the voice were called *φωνασκοί*, *phonascei*; and under their instructions were put all those who were destined to be orators, singers, and comedians. Roscius had an academy for declamation, at which he taught several persons, preparatory to their speaking in public, or going on the stage. He had a law-suit with one of them, in which Cicero pleaded his cause.

These are proofs sufficient of the dramatic declamation of the ancients being uttered in musical tones, agreeing with those of the musical instruments by which they were accompanied. See DECLAMATION and RECITATIVE.

ROSCOEIA, in *Botany*, being a new and very distinct genus of the natural order of *Scitamineæ*, was dedicated, by the writer of the present article, to his distinguished friend William Roscoe, esq. F.L.S., whose papers in the Linnean Society's Transactions, and especially his New Arrangement of the order in question, printed in their eighth volume, richly entitle him to this botanical honour. Of his

particular observations and discoveries respecting this order, by which he has reduced to clear scientific principles, what had hitherto been an indigested chaos, we shall speak under the article *SCITAMINEÆ*, in its proper place.—Sm. Exot. Bot. v. 2. 97.—Class and order, *Menandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, tubular, cylindrical, its limb sheathing, erect, undivided, membranous at the edge. *Cor.* of one petal, irregular; tube scarcely longer than the calyx, erect, straight, triangular upwards: outer limb ringent, two-lipped; its upper lip broadest, erect, obovate, acute, concave; lower about as long, in two deep, linear-lanceolate, acute, reflexed lobes: inner limb ringent, two-lipped; the upper lip erect, shorter than the outer limb, of two cohering, half-ovate lobes, tapering at the base, and embracing the organs of fructification; lower much longer and broader, spreading, cloven. *Stam.* Filament one, inserted into the top of the tube, short, linear, channelled, erect; anther much longer than the filament, linear, channelled, greatly incurved, bearing pollen in the upper part only, its base extended in the form of two lanceolate, horizontal, ascending, acute, membranous lobes. *Pist.* Germen inferior, oval, very small; style thread-shaped, lodged in the groove of the filament, and of the anther, to whose curvature it conforms; stigma obtuse, concave, downy, just projecting beyond the anther. *Peric.* Capsule? we presume it to be analogous to that of other *Scitamineæ*.

Ess. Ch. Anther two-lobed, incurved, terminal, embracing the style, with a cloven appendage at its base. Outer limb of the corolla irregular; upper lip vaulted; lower deeply divided: inner limb in three parts, two-lipped.

1. *R. purpurea*. Purple Roscoea. Sm. Exot. Bot. v. 2. 97. t. 108. (Hatucon Swa of the Nawars of Nepal.)—This plant was found at Narainhetty, in the mountains of Upper Nepal, by Dr. Francis Buchanan, flowering in April 1802. It is the only species, hitherto discovered, of this very well-defined genus, which should be arranged near *HEDYCHUM* and *KÆMPFERIA*, (see those articles,) to both of which genera it has some points of affinity; but *Roscoea* is distinguished from every other known plant of the *Scitamineæ*, by the irregularity of its two-lipped outer limb, and the peculiar appendages to the base of the anther.

The root is perennial, of several, clustered, spreading, oblong, tapering knobs, producing branched fibres. No aromatic or pungent flavour is perceptible in our specimens. *Stem* solitary, erect, a foot or more in height, simple, leafy, compressed. *Leaves* spreading in two ranks, alternate, oblong, pointed, folded, wavy, entire, smooth, with many oblique parallel veins; pale at the under side; somewhat rounded and heart-shaped at the base, running down into broad, sheathing, compressed, furrowed, purplish footstalks, which embrace and conceal the stem. *Stipula* crowning the inflexure of the footstalk, very short, entire. *Flowers* several, opening in succession, terminal, clustered, sessile, erect, large, and handsome, of a violet-purple, with whitish organs of impregnation; the tube of the calyx of each concealed by the sheaths of the upper leaves.

ROSCOFF, or ROSCOU, in *Geography*, a sea-port town of France, in the department of Finisterre; 4 miles N. of St. Pol de Leon. As a sea-port it is much frequented by those who carry on a contraband trade with England, especially in wine and brandy. The inhabitants used formerly to import linseed, and export linen manufactured in the country annually to the amount of 500,000 livres. Since the

the revolution this trade has been interrupted, but with the return of peace may be easily revived. The harbour, however, without timely precaution, is in danger of being choked up with sand. In the neighbourhood of the town, and throughout the department of Finisterre, the fields are manured with sea-weed. Wood is very scarce, and their fruit-trees occasionally serve for fuel. In the island of Bas they burn cow-dung and sea-weed. Roscoff contains 1000 inhabitants; nevertheless, the depopulation from its loss of trade, the arid sandy ground on which it is built, and the desolated ruins of former establishments, give the place a melancholy appearance of desolation. In this place there is not a single fountain, nor any institution for the instruction of youth, nor any regulation for preserving the health of the inhabitants. This is said to be the place where the chevalier St. George landed, after his unsuccessful attempt in 1745.

ROSCOLÆ, a name given by some medical writers to the measles.

ROSCOMMON, *Earl of*, in *Biography*. See DILLON.

ROSCOMMON, in *Geography*, a county of Ireland, in the province of Connaught, is bounded on the east by the river Shannon, which separates it from the King's county, West-Meath, Longford, and Leitrim; and on the west by Galway, Mayo, and Sligo. Towards the north and south it is contracted into narrow necks of land, between the east and west confines. According to Dr. Beaufort, its length from north to south is 47 miles (60 English), and its breadth about the middle of the county 29 (37 English) miles. The latter varies considerably, being in some parts less than 10 miles. The area measures 346,650 acres, or 541 square miles, equal to 556,847 acres, or 869 square miles, English measure. This county contains 56 parishes, 22 of which have churches. Of these the greater part are under the fee of Elphin. When Dr. Beaufort wrote, the population was estimated at 86,000; what it is at present cannot be ascertained. Roscommon is a flat open country, in some places sprinkled with rocks, in many interrupted by extensive bogs, and but little diversified with hills. The only mountains within the county are in a narrow part between Lough Arrow and Lough Allen; and these are become valuable, on account of the coal and iron which they are found to contain. The lofty Curlew mountains, which join Lough Arrow, separate this county from Sligo. The Shannon beautifully delineates the eastern confines, branching in a course of 50 miles into several fine lakes, of which Lough Ree, Lough Baffin, and Lough Allen, are the largest. The Suck divides it from Galway for a great length of way, till it loses its name and waters in the Shannon. A number of small streams from the interior intersect the county, fertilizing and enlivening the fields. The largest of the lakes is Lough Key, in the north of the county, which is rendered delightful by wooded islands and surrounding groves. The soil is fertile; lime-stone and marl are abundant, and the climate not severe. The county has long been famed for its pastures; but as population increases, wants and cares are augmented, and pasturage gives way to tillage, as a more abundant source of supply. Hence we find, that although pasturage is calculated to cramp population, yet, by the introduction of manufactures, it may be so increased, that pastures must be broken up and tilled. This natural course of events has operated very powerfully in Roscommon. The manufacture of linen and woollen stuffs has been diffused; bounties have also been offered for farinaceous produce; and under these necessities and incitements, pasturage has considerably decreased. It has been contended, that converting such rich pastures to tillage

must prove a great loss to the country; but although the land cannot, for a considerable time, so fully repay the labours of the husbandman, as when in the zenith of their pastoral utility, yet in the end there cannot surely be a doubt of their more amply remunerating the country. In the pastoral economy of this district we find sheep the largest proportion of the farm-stock: bullocks and cows form a lesser share. Mr. Wakefield commends the quality of both. The farms are generally divided by stone-walls. Agriculture is in its infancy, but the abundance of lime-stone has contributed, in a great degree, to promote the extension of tillage. This is conducted on the same plan as in other parts of Connaught, and is thus described by Dr. M'Parlan. "The mode of culture is with a long narrow spade, commonly called a loy. This machine they prefer to ploughs, and assign many reasons for doing so. The hills are very steep, (speaking of Leitrim,) beset with stones; and notwithstanding the soil being generally gravelly, so tough and retentive of wet, as to render ploughing objectionable. They also complain of a scarcity of horses: but, above all, they assign, as a peculiar inducement, the abundance of crop produced by the loy culture compared to that of the plough. In some of the more level parts, ploughing is in practice; and in some others they unite both, first ploughing, then mincing and dressing with the loy. The soil being in general of the stiff argillaceous kind, wherever it is so, the potatoes are planted by dibbling with the *sheven*. In a few places they plant, by spreading the cuts on the dung or green turf, and then digging up the furrows; and in still fewer, where the soil is light and friable, they plant potatoes by drilling with a one-horse plough, particularly in stubble and old potatoe ground." Mr. Wakefield calls this a faithful picture of the cultivation of this district. Roscommon is the shire-town, but Boyle is more thriving. None of the towns are large. The county is represented in parliament by two members only. Beaufort. Wakefield. Robertson.

ROSCOMMON, a post-town of Ireland, and the shire-town of the county of the same name, where the assizes are held. It is situated about three miles from the Shannon, where it expands into Lough Ree. It is a small place, agreeably situated, but has little trade. The ruins of a Dominican friary exhibit some remains of elegant architecture, especially a tomb of Felim O'Connor, king of Connaught, adorned with a number of emblematical devices. Roscommon is 69 miles W.N.W. from Dublin.

ROSCOTTY, a town of Thibet; 18 miles W. of Sirinagur.

ROSCREA, a post-town of the county of Tipperary, Ireland, on the border of the King's county. It is a neat and thriving town. The church is very ancient, and has a curious frontispiece at the west end. Near it stands one of the largest round towers in Ireland, all built with square stone, which is unusual in these edifices. Roscrea was once a bishopric, but was united with Killaloe in the twelfth century. The large old castle was built by the Ormond family. It is 59 miles S.W. from Dublin.

ROSE, in *Botany and Gardening*. See ROSA.

It is a tradition among the ancients, that the god of love made a present to Harpocrates, the god of silence, of a beautiful rose, the first that had been known, to engage him not to discover any of the private practices of his mother Venus. And hence it became a custom to have a rose placed in their rooms of mirth and entertainment, that under the assurance thereof they might be induced to lay aside all constraint, and speak what they pleased. Thus did the rose become a symbol of silence; so that to be *sub rosa*, under the

*rose*, denotes as much as to be out of danger of having any conversation divulged.

ROSE Bay. See NERIUM.

ROSE, *Campion*. See AGROSTEMMA.

ROSE, *China*, the name by which some call the ketmia of botanists. See HIBISCUS.

ROSE, *Christmas*. See HELLEBORUS.

ROSE, *Corn*. See PAPAVER.

ROSE, *Mountain-bay*, or *Dwarf-bay*, a name by which the chamærhodendros of botanists is sometimes called. See KALMIA, and RHODODENDRUM.

ROSE, *Guelder*, a name sometimes given to the opulus, or water-elder. See VIBURNUM.

ROSE, *Virginian Guelder*. See SPIRÆA.

ROSE, *Martinico*. See HIBISCUS.

ROSE of *Jericho*, a name by which some call the hesperis. See ANASTATICA.

ROSE *Mallow*. See ALIZA.

ROSE, *South Sea*, a name sometimes given to the *Nerium* of botanists; which see.

ROSE, *Rock*. See CISTUS.

ROSE-*Root*. See RHONIOLA.

ROSE, in the *Materia Medica*. The flowers of the *Rosa canina*, dog-rose, or hep, are said by some botanists to be inodorous, and yet their fragrance is often very perceptible. The fruit called heps, or hips, has a pleasant acidulous taste, depending on the uncombined citric acid and sugar which it contains. This pulpy fruit is cooling, but possesses no specific medicinal virtue. It is used in the preparation of a conserve or confection. For this purpose the London pharmacopeia directs a pound of the pulp and 20 ounces of refined sugar, in powder, to be rubbed together until they be well incorporated; and in the Edinburgh Dispensatory, it is ordered, that the fresh fruit of the dog-rose, carefully freed from the seeds and inclosed spicula, be beaten into a pulp, and, while beating, that three times its weight of double refined sugar be gradually added. (See CONSERVE). Formerly, says Woodville, it was esteemed useful in many disorders, as dropics, calculous complaints, dysenteries, hæmorrhages, &c. A moss-like excrescence, called "Badeguar," "Rose-sponge," and by the French "Galle cheveluë," is frequently found upon the branches of this tree, and is the habitation of the insect called "cynips rosæ." This excrescence was formerly in great repute as a remedy for various diseases.

The *Rosa centifolia*, or hundred-leaved rose, of which there are many varieties, is improperly confounded in the Dublin pharmacopeia with the damask rose, *Rosa damascena*, which is altogether a different species. The petals of this species are directed for medicinal use. They are of a pale red colour, and of a very fragrant odour, which is to many people very agreeable, and therefore this as well as most of the other roses, are made up into nosegays: and these, in some circumstances, have produced alarming symptoms, such as sneezing, inflammation of the eyes, faintings, hysterical affections, abortion, &c.: and persons confined in a close room, with a large quantity of roses, have been in danger of immediate extinction of life. The petals impart their odorous matter to watery liquors, both by infusion and distillation. Six pounds of fresh roots impregnate, by distillation, a gallon or more of water strongly with their fine flavour. On distilling large quantities, there separates from the watery fluid a small portion of a fragrant butyraceous oil, which liquefies by heat, and appears yellow, but concretes in the cold into a white mass: 100 pounds of the flowers, according to the experiments of Tachenius and Hoffmau, afforded scarcely half an ounce of oil. The smell of this

oil exactly resembles that of the roses, and is therefore much used as a perfume.

The oil of roses possesses very little pungency, and has been highly recommended for its cordial and analeptic qualities. The flower also contains a bitterish substance, which is extracted by water along with the odorous principle, and remains entire in the decoction after the latter has been separated by distillation or evaporation. This fixed sapid matter of the petals manifests a purgative quality, and it is on this account that the flowers are received in the *materia medica*. The pharmacopeias direct a syrup to be prepared of this rose, which is ordered as an adjunct to oil and other purgatives in the diseases of infants; but they are chiefly employed for the distillation of rose-water. The London pharmacopeia directs seven ounces of the petals of the hundred-leaved rose dried to be macerated in four pints of boiling water for 12 hours, and to strain it; and then to evaporate the strained liquor in a water-bath down to 2½ pounds, and to add six pounds of refined sugar, so as to make a syrup. This syrup is prepared, according to the Edin. Pharm. by macerating one pound of the fresh petals of the *rosa centifolia*, or, as it is erroneously denominated, damask rose, in four pounds of boiling water for 12 hours, and adding three pounds of refined sugar to the strained liquor, and boiling so as to form a syrup. This syrup, in doses of a spoonful, or from fʒij to fʒiij or more, is found to be pleasant and useful as a laxative for children, or to obviate costiveness in adults.

The *Rose-Water*, *Aqua rosæ*, (Lond. and Dub. Ph.), *Aqua rosæ centifolia* (Edin.) is prepared by taking 8lbs. (Lond.), 6lbs. (Edin. and Dub.), of the petals, and pouring over them as much water as will prevent empyreuma during the distillation; and then distilling a gallon (Lond. and Dub.), or 10 pounds (Edin.) This water has the agreeable odour of the rose in great perfection, when properly prepared; but it is very apt to spoil, unless it be rectified by a second distillation. As it is free from acrimony, and, except in point of odour, does not differ from distilled water, it is generally employed in collyria, with acetate and superacetate of lead, and acetate and sulphate of zinc. The oil and water, obtained by distillation, and used chiefly in perfumes and flavouring materials, are recommended by Hoffmau as excellent cordials for raising the strength and spirits, and allaying pain. They appear to be of a mild nature, and not liable to heat or irritate the constitution. Rose-water is, however, in great esteem throughout the East, particularly in China and Persia, where the trade of it is very considerable. The rose-leaves, remaining at the bottom of the still, are kept under the name of rose cakes for a perfume.

The flowers of the *Rosa gallica*, or red officinal rose, give out their virtue both to water and rectified spirit, and tinge the former of a fine red colour, but the latter of a very pale one. The extract obtained by inspissating the watery infusion is moderately austere, bitterish, and subsaline. The spirituous extract is considerably stronger both in astringency and bitterness. Water at 212° extracts both its odour and taste; and the infusion strikes a black with sulphate of iron; and also forms a precipitate of a dark colour with sulphate of zinc. The red rose is astringent and tonic. It forms an useful and elegant vehicle for the exhibition of mineral acids, nitrate of potash, and other neutral salts, in hæmorrhages and some other diseases. It has been said, that the flowers of this species possess neither the fragrance nor the laxative power of those of the *centifolia*; but Poterius, cited by Lewis, relates, that he found a drachm of powdered red roses occasion three or four stools, and this not in a few instances,

instances, but constantly in several. Its fragrance is improved by drying; and both the allringency and the colour of the petals are best preserved by hasty exsiccation. Its flowers are chiefly valued for their astringent qualities, which are most considerable before the petals expand, and, therefore, in this state they are chosen for medicinal use, and ordered by the pharmacopœias in different preparations, as those of a conserve, a honey, an infusion, and a syrup. These preparations, especially the first and second, have been highly esteemed in phthisical cases, particularly by the Arabian physicians; who mention some in which they were effectual remedies. The case of Kruger, related in the German Ephemerides, has been thought a more evident proof of the efficacy of the conserve of roses in phthisis pulmonalis; but as the use of the conserve was commonly joined with that of milk and farina-cæa, together with proper exercise in the open air, it has been doubted if these recoveries could be wholly imputed to the roses, though their mild astringent and corroborant virtues certainly contributed much. In some of the cases above alluded to, 20 or 30 pounds of the conserve were taken in the course of a month.

The *Confectio rose gallica*, confectio of the red roses of the Lond. Pharm. is prepared by beating a pound of the unblown petals of the red rose, freed from the claws, in a stone mortar, and adding three pounds of refined sugar, and then beating again until the whole be thoroughly incorporated. The Edin. Pharm. directs the unblown petals of the red rose to be beaten to a pulp, and during the beating to add three times their weight of refined sugar. The *Conserva rosæ*, or conserve of roses of the Dubl. Pharm. is prepared by beating the unblown petals of the red rose, freed from their claws, and adding gradually three times their weight of refined sugar. The confectio of the red rose possesses a small degree of astringency, and is sometimes given dissolved in new milk as a tonic in early convalescence from acute diseases; but its chief use is to form a pleasant vehicle for more active medicines.

*Mel Rosæ*, or rose honey. See HONEY.

*Infusion of Roses*. See INFUSION.

*Syrup of red roses*, *Syrupus rose gallicæ*, is prepared, according to the Edin. Pharm. by macerating seven ounces of the dried petals of the red rose in five pounds of boiling water for 12 hours, then boiling a little and straining; and adding six pounds of refined sugar to the strained liquor, and again boiling a little so as to form a syrup. This syrup is a weak astringent; and as such is added to astringent and stomachic infusions and gargles: it is useful in hæmoptysis and some other hæmorrhagic complaints as a gargle, and its efficacy chiefly depends on the acid; but it is principally valued on account of its flavour and colour. Lewis Mat. Med. Woodville Med. Bot. Thomson Lond. Disp.

*ROSES*, *Essence of*. There is scarcely a more valuable perfume in the world, than the essence of damask roses, and scarcely any thing is obtained from its subject with more difficulty, and in less quantity. All essences or essential oils are, while in the plant, contained in certain vesicles lodged in different parts, and of different structure; these vesicles are in the rose particularly small and tender, and are placed very superficially; the consequence of this is, that there is originally but a very little of this essence in the flower, and this is the very subject that will be dissipated and lost when the flowers are gathered and thrown in a heap together, as they are succulent, and very quickly heat in lying together. To avoid all dissipation and waste of this choice essence, the roses should be thrown into the still as soon as gathered, and distilled with very little water, and

that in a *balneum Mariæ*; then the fire is to be continued so long as the flowers float separate about in the water; but as soon as ever they form themselves into a cake, and stick to the bottom, the distillation should be finished, as they then yield no more essence. With all these precautions, however, it is with great difficulty we can procure any essence of roses. What we obtain by this distillation being chiefly a very odoriferous and fragrant water. In the warmer countries the same caution affords a larger quantity of oil, which may be separated and preserved under the name of the essence. In Italy, they make some quantity of it, but there it is very dear; a vast quantity of the flowers yielding only a very little essence, and that being thick and troublesome in the procuring, as it every where sticks to the vessels.

It is to be observed, that the season of the year as to wet or dry, makes a very great difference in the essential oils of all plants; they are always much finer in dry and hot seasons, than in cold and moist; we find our rose-water in England much finer, and more fragrant, though distilled in the same proportion, in hot and dry summers, than in cold and rainy ones; and Mr. Geoffroy gives an account that he succeeded, one very hot and dry year, in the making essence of roses in France in the following manner.

As the roses were brought to him fresh gathered, he turned them immediately into the still; and drawing over the water into a glass matras, when it had stood by some time, and was perfectly cold, he discovered some of the essence fixed to the sides of the matras, and the surface of the water covered with a thin reticular pellicle. All the contents of the matras were put to filter through a paper, supported by a fine linen cloth; and the filtrated water was added to new roses for many succeeding distillations, the produce of which was all filtered through the same paper. After a long course of distillations, with fresh flowers every time, but still with the same vessels and the same water, there was found in the paper of the filtre a quantity of thick essence; this being carefully washed out of the paper, with a small quantity of the most fragrant of the water, and afterwards separated pure from its surface, was very white and extremely fragrant, and as thick as fine butter. This is not the only essential oil which naturally concretes into this firm state; oil of aniseed, though fluid when distilled, always concretes in the same manner on the first approach of cold; and another oil of this kind is that of the laurel, which is used in some places, though very improperly, to give the scent and taste of bitter almonds, or apricot kernels, to foods of different kinds.

Monseigneur Homberg has taught us how to gain a larger quantity of the essential oil of roses than in the usual distillation, by the previous addition of mineral acids, as the spirit of salt, vitriol, &c. thereto; which increase the fermentation, and joining with the oil, render it more liquid, and easier to be raised by heat. He advises a perfumer (who before scarcely obtained an ounce of oil from a hundred weight of roses) to steep his flowers, for fifteen days, in water made sharp with the spirit of vitriol; by which means the perfumer, upon distillation, found his quantity of oil increased almost a third.

The perfumers keep the structure of the vessel they employ in this distillation a great secret. M. Homberg tells us, it is a large convenient still, that opens in a tube at the top to receive the water, which must often be poured upon the roses, to bring over the oil with it; this it does but very slowly, and so requires that its quantity be large; the still also opens below, that the flowers, when they will yield no more oil, may be easily taken out; but the principal contrivance

contrivance is the figure of the vessel which receives the oil ; this is made like an ordinary matras, from the lower part of the belly of which comes a tube, as from an old-fashioned cruet, and rising to the bottom of the neck of the receiver, it bends outward ; so that though the vessel usually contains but two or three French pints, it conveniently receives and lets pass many hundred pints of the rose-water, without any necessity of being changed ; for a change would lose the small quantity of the oil obtained. The water distilled runs through a pipe into a second receiver ; the oil, being lighter than the water, floats upon its surface, and adheres to the neck of the vessel, as high as the aperture of the little pipe, while the water runs from the bottom of the first receiver into the second. See *Mém. de l'Acad. des Sciences*, 1700.

M. Homberg observes, that this still may be useful to draw off any kind of precious essential oils.

The process for making attar, or essential oil of roses, so much esteemed as a perfume, is related in the "*Asiatic Researches*," (vol. i. p. 332.) by lieutenant-colonel Polier, and is as follows. "Forty pounds of fresh roses, with their calyces, but the stems cut close, are put in a still with 60 pounds of water. The mass is then well mixed together with the hands, and a gentle fire is made under the still. When the water begins to grow hot, and fumes to rise, the cap of the still is put on, and the pipe fixed ; the chinks are then well luted with paste, and cold water put on the refrigerator at the top. The receiver is also adapted at the end of the pipe ; and the fire is continued under the still, neither too violent nor too weak. When the impregnated water begins to come over, and the still is very hot, the fire is lessened by gentle degrees, and the distillation continued till thirty pounds of water are come over, which is generally done in about four or five hours. This rose-water is to be poured again on a fresh quantity (forty pounds) of roses ; and from fifteen to twenty pounds of water are to be drawn by distillation, following the same process as before. The rose-water thus made and cohobated, will be found, if the roses were good and fresh, and the distillation carefully performed, highly scented with the roses. It is then poured into pans either of earthen-ware or of tinned metal, and left exposed to the fresh air for the night. The *attar*, or *essence*, will be found in the morning congealed, and swimming on the top of the water. This is to be carefully separated, and collected, either with a thin shell or a skimmer, and poured into a vial. When a certain quantity has thus been obtained, the water and feces must be separated from the clear essence, which, with respect to the first, will not be difficult to do, as the essence congeals with a slight cold, and the water may then be made to run off. If, after that, the essence is kept fluid by heat, the feces will subside, and may be separated ; but if the operation has been neatly performed, these will be little or none. The feces are as highly perfumed as the essence, and must be kept after as much of the essence has been skimmed from the rose-water as could be. The remaining water should be used for fresh distillations, instead of common water ; at least as far as it will go.

"The above is the whole process of making genuine attar of roses. But, as the roses of this country give but a very small quantity of essence, and it is in high esteem, various ways have been thought of to augment the quantity, though at the expence of the quality. In this country it is usual to add to the roses, when put in the still, a quantity of sandal-wood raspings, some more, some less, from one to five tolahs, or half ounces. The sandal contains a deal of essential oil, which comes over freely in the common distilla-

tion, and mixing with the rose-water and essence, becomes strongly impregnated with their perfume. The imposition, however, cannot be concealed ; the essential oil of sandal will not congeal in common cold ; and its smell cannot be kept under, but will be apparent and predominate, in spite of every art. In Cashemire they seldom use sandal to adulterate the attar ; but I have been informed, to increase the quantity, they distil with the roses a sweet-scented grass, which does not communicate any unpleasant scent, and gives the attar a high clear green colour. This essence also does not congeal in a slight cold, as that of roses."

The quantity of essential oil to be obtained from the roses is very precarious, as it depends not only on the skill of the distiller, but also on the quality of the roses, and the favourableness of the season. In order to obtain 4 mashes (about  $1\frac{1}{2}$  drachm) from 80 pounds, which, deducting the calyces, amounts to something less than 3 drachms per 100 pounds of rose-leaves, the season must be very favourable, and the operation carefully performed. The colour of the attar of roses is no criterion of its goodness, quality, or country. In the year 1787, Col. Polier had attar of a fine emerald green, of a bright yellow, and of a reddish hue, from the same ground, and obtained by the same process, only of roses collected at different days. The calyces, he observes, do not in any degree diminish the quality of the attar, nor impart any green colour to it ; though perhaps they may augment the quantity ; but the trouble necessary for stripping them must, and ought, to prevent its being ever put in practice.

ROSES, *Oil of*. See ROSE, and the preceding article.

ROSE-Fly, in *Natural History*, the name given by authors to a peculiar species of fly, found very frequent on rose-bushes, and produced out of a bastard caterpillar, which feeds on the leaves of that tree. See CYNIPS.

The male of this fly has a long body, the female a short and thick one ; she deposits her eggs in small holes, which she makes in the bark of the young branches, and for this purpose is furnished with a very remarkable instrument, placed at the hinder part of the body, which is a kind of saw.

This is a four-winged fly, and is so common on rose-bushes, that it is scarcely possible to miss it in any of the summer months ; and the parts of the branches where it has deposited its eggs are so vitiated by it, that they also are easily known. They are usually swelled to a greater bigness than either the part above or below them, and are usually somewhat bent ; they are often black on the under side, and among this blackness the holes made for the eggs, and often the eggs in them, may be seen. The head and breast of this fly are black ; its wings also are edged with black, its body is yellow, and its legs yellow, with a few black spots.

If these flies be observed in a summer morning, as they are crawling on the branches of a rose-tree, they will soon be found at work for the depositing of their eggs. These creatures give us a very good opportunity of observing the manner in which they perform this, as they are of a very sluggish disposition, and will stand still even to be taken between the fingers ; so that when one of them is in a proper situation, it may be examined by bringing the eye near it, and by using the common magnifying glasses, without quitting its place or its work ; and if there be leaves of the tree, or small branches of it in the way, they may be removed without disturbing the creature. *Reaumur's Hist. Inf.* vol. ix. p. 145.

There is, besides this species, another fly of the same genus, produced from a bastard caterpillar of the rose-tree, and of the same shape and structure of parts with this, but different

different in colour. The head and breast of this fly are of a deep violet colour, the body is yellow, and the legs and wings are of a somewhat paler violet tinge. This creature also deposits its eggs in holes made in the branches of the rose-tree, by means of a double saw, placed at the hinder part of the body; but, as the former species lays them in a single straight line, this disposes them in a very beautiful and very regular manner in two rows.

*ROSE-Galls*, a name given by authors to certain unnatural productions of the *rosa sylvestris*, or dog-rose, occasioned by the bites of insects. There are two kinds of these, the one very common, the other more rare.

The scarcer kind is usually found on the young shoots, and on the hips, or fruit, and is of a woody substance; the other is hairy and spongy, and is found on the old branches. The woody kind usually appears in the months of June and July, and is always found in clusters. These are composed of ten, twelve, or more galls of different sizes and figures, some round, others oblong, some of the size of an olive, and others not larger than a pea. They are of the common substance of the white wood, or blea, of trees, and when situated on the fruit, they prevent its ripening, and make a very singular figure. They are of a reddish colour, and are usually smooth and glossy, but sometimes they are beset with short and fine prickles.

The hairy rose-gall is too common, and too singular a figure to have escaped the observation of persons in all ages; it has been introduced into medicine in many parts of the world, and is at this time prescribed in Germany, when reduced to powder, in diarrhoeas, dysenteries, and other disorders of the bowels, and to promote urine and break the stone.

These rose-galls, though they appear at first sight composed of tufts of hair, are, however, in reality, made up of several small galls, growing from a bud on the branch, and forming a cluster on the part. They are of an oblong figure, and resemble the shape of a plum-stone. Each of them is the habitation of a single worm, each having one cell in the centre.

All these galls of the rose-tree afford the same species of worms and flies. The proper inhabitants, however, are hardly to be distinguished by the most curious observer from the great variety of species which are found in them, all produced of the eggs of other flies, whose worms are of the carnivorous kind, and are lodged in the gall, not to feed on the juices of the tree, but on the flesh of the proper inhabitant. When the parent-fly, who gives origin to the galls, has deposited her eggs, and the tumour, in consequence, begins to be formed, an enemy of this kind pierces the covering, and sends in her offspring to feed on the inhabitant. These are flies of the ichneumon kind, and several species of them are of great beauty. All the flies described by authors as issuing out of this gall seem to have been of this kind; the proper inhabitant, being a small black fly of no great beauty, is disregarded, while the others have been particularly described.

Mentzelius has given an elegant account of a species whose back is of a fine blue, and its belly purple; and others have figured and described greenish and gold-coloured ones; but these are all ichneumons, all bred of devouring enemies which have fed on the proper inhabitants of the galls, and lived and transformed themselves in their cells.

*ROSE-Wood*, *lignum rhodium*, or *aspalathum*. See ASPALATH.

*ROSE Pink*. See PINK.

*ROSE, Golden*, is a rose which the pope blesses at mass, on the first Sunday in Lent, while they sing *Lætare Jeru-*

salem; and which, after mass, he carries in procession; and then sends as a present to some sovereign prince.

*ROSE, the factions of the red and white*, are famous in our English histories. They had their rise in 1454, under Henry VI. between the houses of York and Lancaster, and ended in Henry VII. who united the two branches. The house of Lancaster had for its badge a red rose; that of York a white one.

*ROSE, in Architecture and Sculpture*, an ornament cut in resemblance of a rose.

It is chiefly used in friezes, corniches, and vaults of churches, and particularly in the middle of each face of the Corinthian abacus. And in the spaces between the modillions, under the plafonds of corniches.

*ROSES, in Heraldry*, is a difference denoting the seventh son of a family.

*ROSE-Nails*. See NAIL.

*ROSE-Diamond*. See DIAMOND.

*ROSE-Noble*, an ancient English gold coin, first struck in the reign of Edward III. when the series of gold coinage commences, and then called the *penny of gold*; since called *rose-noble*, because stamped with a rose. It was current at 6s. 8d., and consequently formed half a "mark," so called as being a grand limited sum in account (Marc, *limes*, Goth.), 8 oz. in weight, and  $\frac{3}{4}$ ds of the money pound. This, as one half of the commercial pound of 16 ounces, is sometimes called "seibra." The noble (which see) was so called from the nobility of the metal, being of the finest gold then, or now, used in the world for coinage; and it was attended by its half and quarter; the proportion of silver to gold being then 1 to 11. This coin was sometimes called the "rose-noble," from both sides being impaled in an undulating circle, resembling the outline of an expanded rose, together with its half and quarter; and these continued the only gold coins till the angels of Edward IV. 1465, stamped with the angel Michael and the dragon, and the angelets, equal to half the angel, or 3s. 4d. were substituted in their place. Antiquaries likewise assert, that gold being scarce in Henry Vth's time, that prince diminished the noble, retaining its former value; but that Henry VI. restored it to its size, and caused it to pass for 10s. under the new name of ryal. Accordingly, the noble of Henry V. weighs only 108 grains now, while those preceding his reign weigh 120. This speaks gold to have increased in value about 10 per cent. The old noble of Edward III. and Richard II. at 120 grains, passed but for 6s. 8d.; but in the fifth year of Edward IV. 1465, the angel was of equal value, though but 80 grains in weight; which shews gold to have increased in value then no less than 30 per cent. Certain it is that the ryal of 10s. and the angel of 6s. 8d. with their divisions of half and quarter, were the sole gold coins till, in 1485, Henry VII. published the double ryal, or sovereign, of 20s. accompanied by the double sovereign, of 40s. See MONEY.

*ROSE Engine, Rose lathe, or Figure lathe*, in the *Mechanic Arts*, is a machine used for turning any articles in wood, ivory, or metal, in the same manner as a common lathe, but it has additional parts, by which the surface of the subject which has been turned, can afterwards be engraved with a great variety of patterns of curved lines, which, in general, are denominated from the French *rosette*, from a slight general resemblance which they have to a full-blown rose, and hence the machine is called a rose engine.

This machine, as we have said, contains all the parts of the *lathe*, (see that article,) and in the same manner as in turning, the work is caused to revolve, whilst the cutting tool is kept stationary; but the difference between the rose lathe

## ROSE-ENGINE.

lathe and the common lathe is, that in the former the centre of the circle, in which the work revolves, is not a stationary point, but a slight motion is given to the centre whilst the work is revolving upon it, the tool being all the while stationary; the surface of the figure which it forms will be, of course, out of round, *i. e.* it will deviate from the circular figure as much, and as often, as the motion is given to the centre.

The art of turning curiosities in wood or ivory, is one of those which is best adapted, of any of the mechanic arts, as an amusement for persons who either have leisure to apply to such subjects, or who require relaxation from mental studies: it has long been a favourite pursuit of many gentlemen, and the machines they employ are very ingeniously constructed. The curious in this art reckon two points of perfection in their works, one where the extreme delicacy, or elegance, of the object renders it admirable, and the other is considered from the difficulties of the execution; the former may be judged by all persons possessed of good taste, but to judge of the latter requires some knowledge of the art, or, at least, so far as to know that the lathe will form only such articles as are perfectly circular, all the parts having a common axis; therefore the specimens of turning are to be more or less esteemed, in proportion as they are more opposed to the circular figure. This art was more cultivated a hundred years ago than at present, and more curious specimens were then produced, such as hollow balls of ivory, containing many excentric figures, formed within each other, all being cut from the same solid piece, and every one beautifully ornamented upon the surface, although only small holes were left through them to gain access to the interior ones: this was carried so far as to form twelve balls of ivory one within the other. A great collection of curiosities of this kind will be found in a French work entitled "Récueil d'Ouvrages Curieux dans le Cabinet de M. Grollier de Servir," 4to. Lyons, 1719. This contains drawings of some very curious articles; but although the art is not so generally practised at the present day as formerly, the machines which are now invented are vastly superior, and, with the same attention, would doubtless admit of the curiosities being equally extended. Messrs. Holtzapffel and Deyerlien, of Cockspur-street, London, have made many improvements in the construction of rose engines, which they execute, as well as all other tools, for ornamental turning, in the most finished style. We have obtained drawings of one of these, see *Plate III. Engines*, in which *fig. 6.* is an elevation in front of the machine. A A B B is the wooden frame; D, the large foot-wheel, to give motion to the mandrel, or spindle, T T, by the band and pulley F. The work is fixed in a chuck I, at the extremity of the mandrel; and the tool is held by the slide-rest K, which, though it has the means of moving the tool a small quantity, to adjust it to the radius of the rose, or figure intended to be cut, still it will firmly retain the position in which it is placed. The upper part, A, of the frame of the machine is made of mahogany, but has within it a cast-iron frame, consisting of two bars, or bearers, which being placed parallel, and at a small distance asunder, leave a groove or opening between them, in the same manner as the cheeks of any other lathe, for the reception of the tenon, at the lower end of the back puppet (shewn by the dotted lines) L, which is used to support the end of a long piece of work; though this is seldom used, because the work can only be turned circular, when the back centre supports it. All work which is to be figure-turned must be held in a chuck, screwed on to the end of the mandrel T; because it is only the mandrel which is moveable, to give those deviations from the circular figure, which are necessary to form the

figured work. For this purpose, the two standards, G and H, which support the mandrel, are not firmly fixed to the bed, A, of the machine, as in other turning-lathes; but they descend between the cheeks or cast-iron bed, almost as low as the bottom of the mahogany bed A, and have there an axis P (dotted), which is parallel to the mandrel, and supported on pivots at its ends; these pivots being received in pieces of cast-iron, descending from the cheeks, and strengthened by the iron bar, Q, extended between them. The two standards, G, H, are formed of one piece, and have a strong bracing of iron between them, in addition to the axis P; but this cannot be seen in the figure, because it is concealed between the cheeks of the bed O. The oscillating motion is given to the mandrel by means of metal rosettes M: these are wheels, fixed upon the mandrel, each having its periphery indented and curved with a waving line, as shewn at M, *fig. 7.* The rosettes are acted upon by a small roller, placed at the end of a piece *n*, which is supported by a triangular bar *m*, fixed parallel to the mandrel, upon the upper ends of curved arms, as shewn in both figures. Now it is evident that when the mandrel revolves, the eminences and depressions of the rosette, applying themselves to the roller of the piece *n*, which is stationary, will cause a vibrating or oscillating motion of the mandrel, and the frame, G H, which contains it. A strong spring is placed within the cavity of the bed A, and applied to the frame of the mandrel; so that it inclines the latter always towards the central or vertical position, that is, the position, when the line of the mandrel is produced, would pass exactly through the point of the screw of the back puppet L; therefore, when the protuberant or waved parts of the rosette causes the mandrel to depart from this situation, the spring will be bent, and ready to force it back, the instant the curvature of the rosette will permit. The spring is slightly curved, and placed in the space between the insides of the iron cheeks of the bed and the frame of the mandrel, so that the middle of the curved part acts thereupon, and the two ends bear against the inside of the frame, to give the re-action. Seventeen different rosettes are placed upon the mandrel, as shewn in a cluster at M, each being of a different pattern. Several are of the kind shewn in *fig. 7*, that is, scoloped out with waves or concave depressions, but differing in the number of waves from 12, as in the figure, to 144, which will, therefore, be very minute. The socket for the piece *n* can be fixed, by its clamp screw, upon any part of the triangular bar *m*, to bring it opposite any one of the rosettes which is required to be used. Other rosettes, instead of having waves or concave depressions, as shewn in *fig. 7*, have convex protuberances. In either case, when the pattern is very fine, the roller upon the end of the bearing-piece, *n*, cannot be admitted, because its curvature would not be sufficiently rapid to suffer it to fall into the depressions. In these cases, therefore, the end of the piece *n* is used for the contact, being rounded, and well hardened and polished, to diminish as much as possible the friction of the rosette revolving, whilst in contact with it.

The slide-rest, which supports the tool, is next to be described: the manner in which it applies to a piece of work, when fixed in a chuck at the end of the mandrel, is shewn in *fig. 6*, whilst *figs. 11* and *12* are on a larger scale to describe it minutely. The rest can be fattened at any part of the bed, by the lower part of the foot, which is supported on the bed, A, of the lathe, and is divided with a dove-tailed groove in the under side, to receive the head of a screw-bolt, going down through the lathe-bed, and fixing it at any place by a thumbnut, as shewn at *k*, *fig. 6*; the groove in the foot is for the purpose of allowing the rest to be moved to and from the

## ROSE-ENGINE.

centre of the lathe, to adjust it to the diameter of the work which is turning. The foot has a strong cylindrical pin fixed upright in the end of it, and this is fitted into a corresponding socket S, formed out of a solid piece, with the lower slider K of the rest; a clamp-screw in the side fixes the socket fast upon the pin, and there is a wheel *s*, cut with notches, at the bottom of the socket, with a catch *t*, fixed upon the foot R, to engage its teeth and hold it fast; by which means the sliders, K, can be fixed, and held fast at any required angle with the mandrel, for purposes we shall hereafter mention.

The upper part of the slide-rest consists of two horizontal sliders, K and *g*, placed in directions perpendicular to each other; to one of these the tool is firmly attached, and by means of screws with handles, the sliders and the tool can be moved in any direction, to follow the tool to the work; K, in both figures, is a frame of metal, formed from the same piece as the socket S; its upper surface is made flat, and upon this a slider, or flat plate, *ee*, is fitted, to move with freedom and precision. A screw is mounted in the opening of the frame, and is tapped into a piece of metal, projecting from the lower side of the slider, so that the screw, when turned round by a handle *d*, fitted on its square end, advances, or draws back the slider, which is guided in a right line by two pieces of brass, screwed to the under side of it, to form a dove-tailed groove, to which the edges of the frame K are fitted very accurately: upon this slider a frame, or two rulers, are screwed, having a second steel slider *g*, fitted in the dove-tailed groove formed between them, and provided with a screw *i*, as the former, to move it. This upper slider carries a piece of metal, with a square hole through it, in the direction of its length, to receive the tool *k*, and a screw at top to fasten it in. The slide-rest being mounted in the manner of *fig. 6*, upon the bed of the lathe, the upper slider, *g*, is parallel with the mandrel, and the lower one perpendicular thereto. For turning flat or face work, the tool is put as there shewn. Now, by turning the screw, *i*, of the upper slider, the tool advances to a contact with the work, which is mounted in a chuck, as in the figure; then by the other screw, *d*, it is moved across the face of the work, turning it as it proceeds to a perfectly flat surface. For turning a cylinder, mounted between centers, the slide-rest is to be turned one quarter round upon the pin in the socket S, so that the upper slider will be perpendicular to the mandrel, and the lower one parallel thereto; in this case, the upper slider must be moved, to adjust the tool to the diameter of the intended work, and the lower slider is moved by its handle *d*, to carry the tool along the length of the cylinder, and cut it as it goes. The whole rest can be fixed at any part of the bed, and can be moved instantly if required. The slide-rest will also turn cones by the following contrivance: the plate, or dove-tailed groove supporting the upper slider, *g*, may be turned round upon the plate *ee*, and fastened at any inclination by a screw passing through a circular groove in the plate. By this means, the upper slider is inclined, in any required angle, to the mandrel, and will then turn a cone, either hollow or solid. The slide-rest presents the tool so firmly to the work, that it will not retreat in the least when any protuberance comes by, but cuts it away, if the strain is not so great as to break the tool: but of this there is no danger if it be properly managed, because the screws advance the tool so slowly, that there is no need to push it forwards suddenly, as it is often unavoidable in turning by hand. The sliders are often divided into inches and subdivisions, by which the work can be made exactly to any dimensions without trouble, or two things may be fitted exactly together. The upper slider, *g*, has a graduated arc to

shew the angle of inclination which it makes with the lower one, when set for turning cones, so that a hollow cone being bored out in a chuck, a solid plug may at once be turned to fit it, without trial, the rest making it certainly of the true angle.

The lathe is put in motion either by the hand, or by the foot of the turner. The latter, when the work is to be turned or reduced to the circular figure, as in any common lathe; and the former, when the work, after being turned, is to be ornamented, an operation which, from its delicacy, requires a very regular motion.

When the machine is turned by the foot, it is done by the pressure upon the treadle E, which acts upon the crank C, on the axis of the foot-wheel, or fly-wheel, D. The motion is communicated from the treadle by a crank-hook, or connecting rod, *a*, fastened to the crank of the wheel, by a collar embracing and turning round at the upper end. When the foot pushes down the treadle, it gives the wheel a rotative motion; and when the crank has been drawn to the lowest point, the momentum which the wheel has thus acquired, draws up the treadle, and thus, by the alternate pressure of the foot, and the momentum of the wheel, the motion is regularly continued. The wheel is made of cast iron, and fixed on the extreme end of the axis; it has two rims of different sizes, and the surface of each is made conical, and cut with three annular grooves, which are recessed, with an angle at the bottom, so as not to have a flat bottom. This form is advantageous, on account of the band having more power to turn the wheel F. These different grooves are made, in order to give different degrees of velocity to the lathe, or to increase the power. The axle of the wheel is made of wrought-iron, except the pivots or centers, and it is bent in the middle to form the crank C: the pivots at the ends are made of hard steel, welded to the iron parts of the axle. The band which connects the fly and mandrel is made of catgut, of such thickness as the nature of the work may require, and is either spliced at the joining of the two ends, or they are fastened together by a steel hook and eye. The band may be either tightened, by shifting it to other grooves in the great wheel, or in the pulley F, of the mandrel; or otherwise by a sliding-piece in the leg B, which is regulated by a screw *x*.

The motion for the hand is given by a small handle O, *fig. 6*; this is fixed upon the end of a spindle, which at the other end carries a small wheel N, communicating by a band with the great wheel D. The spindle is supported in a frame, which is attached to the lathe-frame, by a centre or joint, on which it can be raised up, and fixed by a toothed sector, to tighten the band when it is required.

The pulley F has three or four grooves, of different sizes, to receive the band, and by this means the mandrel may be turned with different degrees of velocity, and made to accommodate itself to the length of the band. The wheel N is made in the same manner.

When a piece of work is to be made in the rose engine, it is first turned true to the size and figure, and then polished, before it is ornamented: therefore the machine is first set to turn circular. For this purpose, the piece *n*, *fig. 7*, is withdrawn, so as to be beyond the reach of the rosette, and a head at *z*, *fig. 6*, being turned, it shoots a double bolt, which locks the frame G H fast in its perpendicular position; that is, when the point of the back centre-screw L will be exactly in the line of the mandrel, the frame being thus rendered immoveable, the machine will turn the same as any common lathe. If the work is of considerable length, it must be supported at the end by the back centre L, at least whilst it is turned circular, previous to being ornamented.

## ROSE-ENGINE.

The back puppet, *L*, is made of cast-iron, and is fitted upon the cast-iron bearers, on which it can be fixed at the required distance from the mandrel by a vertical screw underneath, and a nut, which comes in contact with a horizontal plate or washer below the said bearers. Its centre-screw has a sharp conical point to support the work, and there is a clamp-screw at top to fasten the centre-screw, to prevent it from running back.

The methods of fixing the work to the end of the mandrel whilst it is turned are very numerous, and vary in almost every instance: in general, it is held in a piece of wood, *I*, called a chuck, which is screwed upon the nose of the mandrel *T*, and being bored, or turned out in the manner of a cup, the piece of wood or ivory which is to be turned is driven into it by a mallet till it is firmly fixed: the wood is, of course, cut nearly to a circular figure, before it is fixed in the chuck; it is then wrought with a sharp triangular pointed tool, *b*, which being fixed in the rest, and advanced to the work by the screw *i*, cuts small contiguous grooves on the surface, till it has broken the grain of the wood, and removed all exuberances. The tool being gradually advanced by its screws *d* and *i*, as is required, the work is reduced at length nearly to its intended size and figure, but will be wholly covered with small grooves: to remove these, and render the work even, another tool is next used; this is formed like a narrow chisel, but made very thick, and with an obtuse edge, which is only bevelled on the under side: its edge will remove the eminences between the grooves left by the first tool. The work is then smoothed, by applying to it the edge of a piece of the blade of a broken knife bevelled away; this is held in the hand, and the work is followed up with it, that its sharp edge may scrape away any roughness left by the tools. To polish the wood, a piece of seal-skin, Dutch reed, or glass paper, is held by the hand upon the work as it runs round, and it cuts away a fine powder, making the work smooth enough to receive a polish. This is raised by first applying a piece of bees-wax, till the work is slightly covered with it, then afterwards burnishing or polishing it, by holding a flat piece of hard wood upon it. The finish can be given by the friction of a coarse woollen rag, lightly smeared with olive oil.

Ivory is turned nearly in the same manner, but is polished with chalk and water, and afterwards by the friction of a woollen cloth; or, if it is first touched with an oily rag, and rubbed off with a dry woollen cloth, it will have a very fine surface.

This is only the same process as is used for ordinary turning; but when the work is finished in this manner, the ornamenting is begun by releasing the bolt, *z*, of the mandrel-frame *G H*, and choosing the rosette best adapted to the pattern which is required. The piece, *n*, is set upon the triangular bar, to be in contact with its wave, and will thus give the oscillating motion, as before described; so that when the tool is applied to the work, it will produce a waved or indented surface, or outline, corresponding with the figure of the rosette, instead of the circular figure produced by the common lathe.

If the ornamenting is to be performed upon a flat surface, such, for instance, as the lid or top of a box, it is chucked, as shewn in *fig. 6*, and the point of the tool being applied to it, will cut a waved line. To do this more conveniently, the slider, *g*, is advanced to the work, by pressing it with the hand instead of the screw *i*; for, by lifting up a small spring catch, of which the tail is seen plainly at *3*, *fig. 6*, the slider is released from the nut of the screw *i*, which has no other attachment to the slider than by a tooth on this catch entering into a notch in the nut, and it is pressed into

the notch by a screw *l*. Now, by releasing the screw *l*, lifting up the catch *3*, and drawing back the slider, the tooth of the catch falls behind the nut of the screw, instead of being in the notch; it will, therefore, form a stop, to check the advance of the tool, though it allows it to be drawn back to clear the work, and also to be pushed up towards it by the hand, to cut the line, the stop regulating the depth of the line, as the hand can advance the slider no farther when it meets the nut.

In this manner, a waved line is engraved round the edge of it, such as is shewn in *fig. 9*, the breadth of the line being determined by the depth to which the point of the tool is regulated to penetrate, by turning the screw *i*. The outer line being thus finished, the tool is now withdrawn to clear the work, and the screw, *d*, of the great slider being turned a small quantity, the point of the tool is brought nearer to the centre of the work; here, by pushing up the tool, another line is described; then a third within the second, and so on, at equal distances, until they reach the centre: this makes a very pretty ornament, as in *fig. 9*. It should be observed, that as each line has the same number of waves, or indentations, they will necessarily grow very fine as they approach towards the centre; but at the same time as the deviation from the circular figure is equal in the smallest as well as the largest rings, it follows, that the curves of the waves of each ring, or line, will vary in a very gradual and pleasing manner, being slightly curved at the circumference, and more rapidly towards the centre. This pattern admits of great variety, by employing different rosettes, fine or coarse, concave or convex; but it will always have the waves included in straight lines directed to the centre. A very pretty variation is made by turning the rosette round upon the mandrel a very small quantity every time before a fresh line is described. For this purpose, the rosettes are not fixed fast upon the mandrel, but are fitted thereupon, so as to admit of turning round, being moved by a small screw at the end towards *H*. As an example of the use of this movement, *fig. 10*. is given, which consists of a rose of twenty-four waves. In this, after drawing the exterior line, in the same manner as the former, when the slider is set for the second, the rosette is turned round upon the mandrel a quantity equal to one-fourth of a wave, or one-ninth-sixth part of the whole circle: the circle is now described, and its waves will not fall exactly within those of the former, but a little advanced therefrom. The next time a circle is to be drawn, the rosette is again shifted, and so on. As this is a quantity equal to one-fourth of the space between the waves, it is plain that at every fourth line the waves will fall in lines drawn towards the centre. Still this will not affect the appearance, which will be totally different from the former, (*fig. 9*.) and very superior to it. The concentric lines, in either of these patterns, are made exactly at equal distances, by means of the divisions before-mentioned, upon the slider *K*, or otherwise by divisions made upon a head, which is fitted upon the end of the screw *d*; and the rosettes are set exactly to the quantity they are intended to be turned round, by means of divisions made upon the edge of a circular plate, which is fixed fast upon the mandrel, towards the end *H*, and a line or mark upon the last rosette applies to it. The screw which effects the movement is supported in bearings upon this plate, and acts in the teeth of a wheel, fixed within the hollow of the last rosette. By this means, when the screw is turned round by a key, it causes all the rosettes to turn round together any quantity which the divisions on the circle indicate. On this principle, great varieties of patterns may be made, and they may be greatly diversified by shifting the rosettes alter-

## ROSE-ENGINE.

nately in contrary directions: thus, after eight, twelve, or any other number of rings have been drawn, by gradually shifting them each time, as before described. By reversing the shifting movement to the opposite direction, a total change will be produced; and continuing in this manner for eight or twelve more circles, the rosettes are again to be advanced in the first-mentioned direction, and continued for eight or twelve. This method produces a curious effect, and admits of much variety in the patterns.

After having drawn a waved line, the rosette may be advanced half a division, and then another line drawn, without altering the slide-rest. By this means, the two waved lines will intersect each other, and make a number of loops like a chain of beads. A number of concentric lines of this sort, drawn upon a circle, is very handsome.

We have now shewn the principal distinctions of the patterns which can be described upon a flat surface; but it is evident, that from the number of the rosettes, a very numerous suit of curious combinations can be made. An elliptical and an excentric chuck are adapted to this machine, to screw on at T: a new field is thus opened, which is so extensive as to exercise constantly the taste and fancy of the operator, in producing new combinations, and renders the machine a source of the most interesting amusement. The elliptical and excentric chucks, when applied to a common lathe, will form a great many interesting patterns, but are vastly more extensive with the rose engine. Their construction will be described under TURNING. It is sufficient here to say, that by the elliptical chuck, the waved lines may be drawn in ellipses, instead of circles; and by the excentric, several small waved circles, or ellipses, can be arranged round the circumference of a larger circle, and their intersections produce a very pretty effect.

Another species of rose-turning is performed upon the surface of a cylinder, globe, or cone; whereas that which we have described is only upon the flat surface of a circular piece, or end of the cylinder. To ornament the surface of the cylinder, the slide-rest is turned round one-fourth of a circle, as before described, for forming the cylinder; so that the long slider becomes parallel to the mandrel. In this way the whole surface of the cylinder may be waved; but great care must be taken to advance the tool very gradually, because it will not cut so readily as when turning circular work. By dividing the length of the cylinder into small equal portions, and by shifting the rosettes every time one of these is finished, the waves may be made to follow each other in a spiral direction round the cylinder; or, by a proper rosette used in this manner, very elegant patterns of basket-work may be formed.

There is another movement of the rose lathe, which we have not yet described: this is called the pumping. It is principally used for describing waved lines upon the surface of a cylinder; that is, the surface is left cylindrical, but the lines are waved in the direction of the length of the cylinder, or alternately towards its ends. This is effected by making the mandrel move end-ways in its bearings: for which purpose, the necks upon which it turns are made exactly cylindrical, and fitted very correctly to steel collars, which are fixed into the standards, G, H. It has, therefore, liberty to slide end-ways in its collars, when the pumping motion is required. This is given by rosettes waved upon the edge or side, and acting against the side of a piece of steel, such as *n*, *fig. 7*. A spring, *p*, *fig. 6*, is fixed at the end of the frame, and acts against the shoulder of the mandrel, to force it end-ways, and keep the rosette always in contact with the piece of steel. The rosettes, M, are cut in a waved manner upon their sides, as well as upon

their circumferences; and thus a variety of pumping rosettes are obtained. By this means, curious waving lines may be drawn round a cylinder; or, if the motions first described are used in combination with the pumping, the surface of the cylinder may be waved, at the same time that waved lines are drawn upon it. In this case, the two rosettes employed must have the same number of waves. When the pumping motion is used upon face or flat work, such as is shewn in *fig. 6*, it produces very agreeable effects, by rendering the waves of the line, which the tool cuts, alternately deeper and shallower, so as to give fine and strong strokes alternately, in the manner of fine writing: or, if the tool is not set so deep, they will only be cut on one side of the wave, and diminishing gradually, will not be seen on the other, and thus produce a number of new patterns; as the waved lines will consist of detached strokes, cut fine at each end, and deep in the middle.

Many patterns may be cut very expeditiously in the rose engine by means of screw tools: these tools are formed like a broad chissel, but the edge is cut with notches, so as to present a number of points instead of one continued edge. These points are very exactly equidistant, being intended to cut screws; and therefore the teeth are of the proper figure to form the threads thereof. By a tool of this kind six or eight lines may be cut at one operation, instead of the trouble of altering the slide-rest, and cutting each separately; and there will be a greater certainty of cutting them all to the same depth, and exactly equidistant. The mode of cutting screws by this tool is called cutting flying, and is thus performed in the rose, or in any common lathe, without a slide-rest. The intended screw being turned cylindrical, the points of the tool are applied to its surface, so that they will cut, and the tool is regularly advanced up towards the mandrel as it turns round: its teeth will, therefore, instead of describing circles, trace the spirals of a screw on the work; and if the advancement is timed so exactly that in one revolution the tool is advanced the exact quantity of a space between two adjacent teeth, then the second tooth will, at the end of a revolution, fall into the spiral cut by the first tooth, and one complete spiral being thus obtained, it guides the whole tool, by means of the second tooth, regularly along, the first tooth continuing to cut the spiral forwards till a third tooth lays hold, then a fourth, and so on, till the required length of a screw is cut. The trace of a screw being thus made, the tool is pressed deeper, till the threads are fully formed, the turner taking care, every time, that the end-tooth of the tool gets to the end of the screw, to disengage it, and draw it back, for as it could not advance any farther than the shoulder, it would spoil all the threads by cutting them to circular rings.

This method requires great habit and dexterity to give the motion so exactly that it will cause the teeth to fall properly into the spirals cut by their predecessors, and that without any sudden advance at the place, for the screw would then be what is called drunken, that is, its threads would be more inclined at one part of its revolution than at another, and such a screw can never be fitted exactly with its fellow. The habit of cutting screws accurately with the screw-tool, can only be acquired by practice and experience, the only precaution which is taken being to get the lathe-wheel into a regular motion, and at such a rate as has been found, by experience, will be proper for the size of the thread intended to be cut. The rose engine before us has a very complete apparatus for cutting screws, which deserves a particular description. A tube is fitted on the end of the mandrel at *a*, its circumference being cut with a spiral, or screw-thread of the degree of fineness required: this is called the regulator screw.

H is a slider, fitted to the standard H, and moved by a screw:  $r$  is a wheel fixed to this slider, and having several half-circle cavities cut in it, which embrace the screw, as shewn in *fig. 10*: each cavity or socket has a thread in it, corresponding with the regulator screw. The mandrel being made, as before-mentioned, with cylindrical collars at each end, is at liberty to slide endways by the movement of the regulator, when the screw H draws up the socket  $r$ ; therefore, every thing being prepared for cutting the thread, the screw H is turned; this raises up the slider, and socket  $r$ , to touch the regulator; the tool is then applied by the slide-rest, and the lathe being put in motion, the mandrel will move along endways, and also the work with it, so that the tool will cut a screw, although it is held fast by the rest. In this case the screw may be cut by a single pointed tool, but it will be better to use a screw tool which is of exactly the same thread as the regulator. The turner should be provided with a variety of sets of screw tools, and as many regulators,  $o$ , corresponding to them, which are made like a tube, and fitted on the mandrel, being held by a nut. The socket  $r$ , which is made like a wheel, *fig. 10*, can be turned round on its centre, and has six different half-circle notches cut in it, each adapted to a particular regulator; therefore, by turning this wheel,  $r$ , any of the notches can be applied to the regulator  $o$ , when the slider is raised up by the screw H. This screw regulator may be sometimes used to advantage when ornamenting the circumference of a cylinder of wood or ivory, as contiguous circles, or waved lines, may then be cut in a spiral direction, without moving the slide-rest to cut each one separately.

Another part of the rose engine is for the purpose of turning swash work; this is circular work, but the mouldings or other lines traced round the cylinder are inclined to the axis. An instance is seen in the balustrades of old-fashioned stair-cases, where the mouldings are made to suit the inclination of the stairs. To turn this kind of work, a steel circle, or hoop, V, is fitted on the end rosette of the mandrel, so that it can be inclined from the perpendicular thereto at pleasure: by this means it forms a guide for the pumping motion, which will so regulate it as to turn any work of this kind, *viz.* with the mouldings, or other ornaments, arranged in lines round the cylinder, but these lines will incline to the axis of the cylinder instead of being perpendicular to it.

ROSE, in *Geography*, a town of Naples, in Calabria Citra; nine miles N.N.E. of Cosenza.—Also, a town of Virginia; 20 miles S.W. of Charlotteville.

ROSE *Islands*, *Great and Little*, two small islands among the Bahamas; 12 miles N. of Providence.

ROSE *Island*, an island in the North Pacific ocean, near the W. coast of America. N. lat.  $59^{\circ} 35'$ . W. long.  $146^{\circ} 30'$ .

ROSEA, a name given by some authors to the erysipelas, or St. Anthony's fire.

ROSEAU, in *Geography*, now "Charlotte-town," the capital of the island of Dominica, situated in St. George's parish; about seven leagues from Prince Rupert's bay; on a point of land on the S.W. side of the island, which forms two bays, *viz.* Woodbridge's bay N., and Charlotteville bay S. Roseau is about half a mile in length from Charlotteville to Roseau, and mostly two furlongs in length, but of an irregular shape. It contains more than 500 houses, besides cottages occupied by negroes. N. lat.  $15^{\circ} 25'$ . W. long.  $61^{\circ} 27'$ .

ROSECK, a town of the duchy of Carniola; eight miles E. of Gottschee.

ROSEHEARTY, a fishing town and sea-port of Scotland, in Aberdeenshire, with a tolerable harbour; for the improvement of which lord Gardenstone bequeathed by will

a considerable sum of money; four miles W. of Frazerburgh. N. lat.  $57^{\circ} 38'$ . W. long.  $2^{\circ}$ .

ROSEINGRAVE, THOMAS, in *Biography*, an enthusiastic, ingenious, and worthy musician, of considerable eminence in his youth for his performance on the harpsichord and organ, both as a fightman and voluntary player. His intellects, in the latter part of his life, being somewhat deranged, rendered his character so singular, that he merits some notice for his eccentricities, as well as professional abilities.

He was the son of Daniel Roseingrave, who having been brought up in the king's chapel at the same time with Purcell, was first promoted to the place of organist of Salisbury cathedral, and afterwards of St. Patrick's, Dublin. Daniel had two sons, both musicians: one of them, Ralph, succeeded his father at St. Patrick's; the other, Thomas, being regarded as a young man of uncommon dispositions for the study of his art, was honoured by the chapter of St. Patrick's with a pension, to enable him to travel for improvement; and about the year 1710 he set off for Italy. Being arrived at Venice in his way to Rome, as he himself says, he was invited, as a stranger and a virtuoso, to an academia at the house of a nobleman, where, among others, he was requested to sit down to the harpsichord, and favour the company with a toccata, as a specimen *della sua virtù*. And, says he, "finding myself rather better in courage and finger than usual, I exerted myself, my dear friend, and fancied, by the applause I received, that my performance had made some impression on the company." After a cantata had been sung by a scholar of Fr. Gasparini, who was there to accompany her, a grave young man dressed in black, and in a black wig, who had stood in one corner of the room, very quiet and attentive while Roseingrave played, being asked to sit down to the harpsichord, when he began to play, Rosy said, he thought ten hundred d—ls had been at the instrument; he never had heard such passages of execution and effect before. The performance so far surpassed his own, and every degree of perfection to which he thought it possible he should ever arrive, that, if he had been in sight of any instrument with which to have done the deed, he should have cut off his own fingers. Upon inquiring the name of this extraordinary performer, he was told that it was Domenico Scarlatti, son of the celebrated cavalier Alessandro Scarlatti. Roseingrave declared, he did not touch an instrument himself for a month. After this rencontre, however, he became very intimate with the young Scarlatti, followed him to Rome and Naples, and hardly ever quitted him while he remained in Italy, which was not till after the peace of Utrecht, as appears by an anthem which he composed at Venice in 1713, and which Dr. Tudway has inserted in the fifth volume of his Manuscript Collection of English Music, p. 149: "Arise, shine, for thy light is come," Isaiah, chap. lx. There is much fire and spirit in the introductory symphony of a very modern cast. Roseingrave is here erroneously called a student of Christ-church, Oxford, instead of Dublin, whence he had his exhibition.

On his return from Italy in 1720, he settled in London, and brought on the stage and conducted the performance of the opera of "Narciso," or "Narcissus," set by his friend Domenico Scarlatti; being the third opera that was performed in our lyric theatre, after the establishment of the Royal Academy of Music. He composed several additional songs for this opera, in which the singers were signor Benedetto Baldassarri, Mr. Gordon, signora Durastanti, Mrs. Anattasia Robinfon, Mrs. Turner Robinfon, daughter of Dr. Turner, and wife of Mr. Robinfon, organist of

Westminster-Abbey. Roseingrave's additional songs were composed in the style of his friend Momo Scarlatti, in whose music of Narcissus, though there were many new and pleasing passages and effects, yet those acquainted with the original and happy freaks of this composer in his harpsichord pieces, would be surpris'd at the sobriety and almost dulness of his songs. His genius was not yet expanded, and he was not so much us'd to write for the voice as his father, who was the greatest vocal composer of his time, as the son afterwards became the most original and wonderful performer on the harpsichord, as well as composer for that instrument. But it seems impossible for any individual to be equally great in any two things of difficult attainment.

Roseingrave was likewise the editor of the first edition of Scarlatti's Harpsichord Lessons, in 2 vols. long 4to.

His election to the place of organist of St. George's, Hanover-square, was attended with very honourable circumstances. The parishioners, consisting chiefly of persons of rank and fortune, being very desirous of having a good organist, and unwilling to trust to their own judgment, or be teased by the solicitations of candidates of mean abilities, requested Mr. Handel, Dr. Pepusch, Dr. Greene, and Mr. Galliard, to hear the competitors play, and determine their degree of merit.

The candidates were allowed half an hour each to manifest their abilities on the organ, in whatever way they pleased, and then were severally required to play *extempore* on subjects given by the judges. Mr. Handel did not attend in person, but sent his subject. Among the numerous candidates for this place there were several who acquitted themselves very well, during the half-hour of free-agency, by playing with great neatness pieces they had probably studied for the occasion; but when subjects of fugue were presented to them for extemporaneous treatment, they neither knew how nor when to bring in the answer, or even to find harmony for the themes with either hand when they were brought in. Roseingrave, on the contrary, whose style, though too crude and learned for the generality of hearers, when left to himself, treated the subjects given with such science and dexterity, inverting the order of notes, augmenting and diminishing their value, introducing counter-subjects, and turning the themes to so many ingenious purposes, that the judges were unanimous in declaring him the victorious candidate. The late Dr. Arne and Mr. Mich. Christ. Festing, who were both present at this contention, informed us of these particulars, which happened in the year 1726, and spoke with wonder of Roseingrave as an extempore fughist; but confirm'd the general censure of his crude harmony and extravagant modulation, which indeed his printed compositions imply.

Roseingrave having, a few years after this election, fix'd his affections on a lady of no dove-like constancy, was rejected by her at the time he thought himself most secure of being united to her for ever. This disappointment was so severely felt by the unfortunate lover, as to occasion a temporary and whimsical insanity. He us'd to say, that the lady's cruelty had so literally and completely broke his heart, that he heard the strings of it *crack* at the time he received his sentence; and on that account ever after call'd the disorder of his intellects his *crepation*, from the Italian verb *crepare*, to crack. After this misfortune, poor Roseingrave was never able to bear any kind of noise, without great emotion. If, during his performance on the organ at church, any one near him coughed, sneezed, or blew his nose with violence, he would instantly quit the instrument, and run out of church, seemingly in the greatest pain and

terror, crying out that it was *old scratch* who tormented him, and played on his *crepation*.
